Through a judicious mixture of tradition, adaptation and innovation, the Karen people shape the landscape to create and maintain a high level of heterogeneity. From the resultant rich biological diversity, they extract a multitude of materials and products that fulfill nutritional, socioeconomic, aesthetic and spiritual needs. Within swidden fields under cultivation, major crops of upland rice, maize and, increasingly today, cash crops such as cabbage, are intercropped with an astounding variety of traditional swidden products such as beans, eggplants, cucurbits, sesame, chilies, yams, gourds, pumpkins, various greens, and spices. Fruit trees, cotton and medicinal herbs are also planted in these fields (Rerkasem and Rerkasem, 1994).

Further to this diversity of cultivated species, Karen farmers also foster the rapid recovery of secondary growth in the fallows, not only to maintain soil fertility and limit

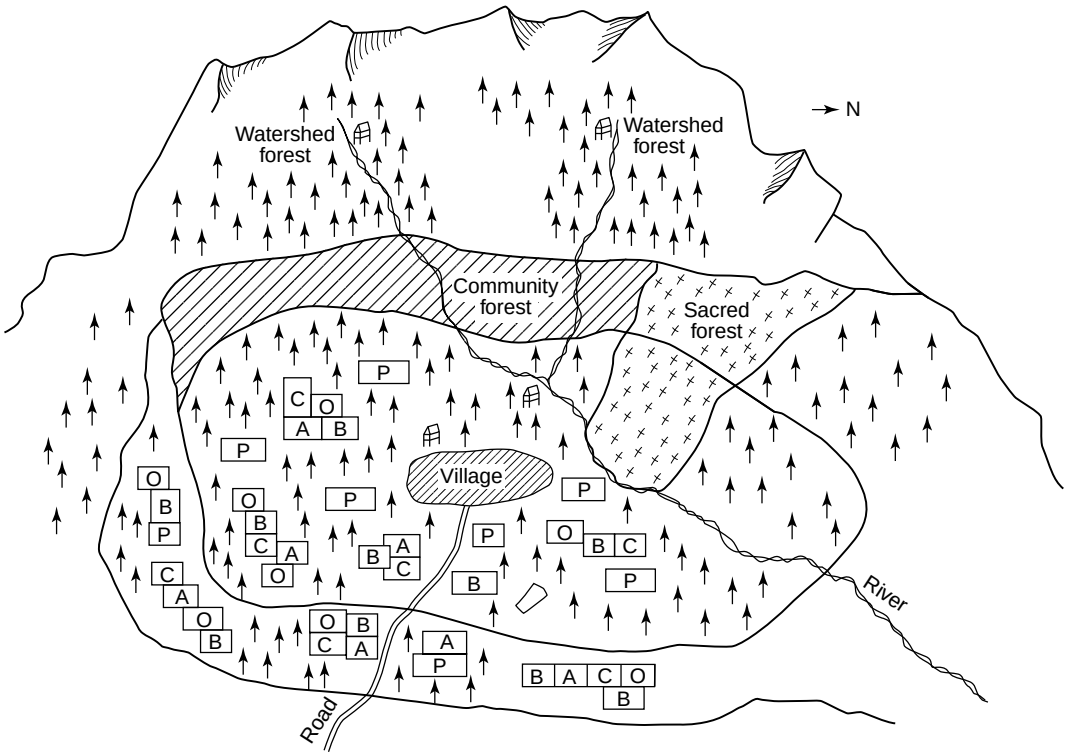

Figure 3 Organization of land use by the Karen of Nong Taw (Chiang Mai Province, Thailand) showing paddy fields (P), swidden fields (O – under cultivation; A – first year fallow; B – 3–4 year fallow; C – 5–7 year fallow), community forest, watershed forest and sacred forest for rituals associated with birth. (Map by J Odochao and C Vaddhanaphuti. Reproduced by permission of Chayan Vaddhanaphuti)

erosion, but also to re-establish a botanical community of which they make full use. When clearing a field for cultivation, branches and brush are left on the ground and burned, providing the soil with nitrogen and carbon-rich ash. Trees are cut well above ground level, leaving roots intact and stumps rising some tens of centimeters above the ground (Figure 4). These stumps sprout quickly, speeding recovery of the forest after cultivation and thus maintaining soil fertility.

Furthermore, plots are distributed so as to ensure that recently used fields juxtapose old fallow plots whose advanced secondary growth speeds the recovery of cultivated lands by providing an abundant supply of seeds. From the first year onwards, the fallow fields provide important supplies of medicinal plants, food in the form of mushrooms, tubers and shoots, as well as areas for the grazing of livestock. After several years, the number of plant species re-established on these sites numbers in the 100s, approaching the biological diversity found in adjacent uncut forest areas, such as the community and watershed forests. The Karen agro-ecosystem also encompasses the use and management of permanently forested lands. Community forests provide wild food products such as mangoes, jackfruit, bamboo shoots, mushrooms, greens and edible herbs, as well as medicinal herbs, firewood, and timber and bamboo for construction. Watershed forests, as vital sources of water for swidden and rice paddy fields, are maintained in a state close to forest climax and strictly protected.

Today the loss of traditional lands to logging interests or commercial plantations and state policies encouraging permanent and intensive agriculture are posing major threats to many swidden cultivators. Less land means shortened fallows and depleted soils, jeopardizing the sustainability of traditional practices. Moving from shifting cultivation to permanent agriculture entails major losses in both biological and cultural diversity, and raises the specter of the millions of hectares of Southeast Asia covered by species-poor *Imperata cylindrica* grasslands, a direct result of the failure of permanent agriculture on phosphorus-poor tropical soils. Rather than import traditional Occidental models of resource exploitation, such as permanent cash monocropping or large-scale non-selective logging, the sustainable practices of small-scale swidden farmers like the Karen should be recognized and supported. They offer numerous benefits including long-term sustainability of local environments and lifestyles, as well as the conservation of domestic crop varieties for many species, and wild plant and animal communities whose biodiversity approaches that of unexploited forest areas and remains far superior to that of permanently cultivated fields. Finally, recent

research suggests that agroforests in general, and shifting cultivation in particular, can contribute significantly to carbon sequestration, by replacing conventional monocropping or *Imperata* grasslands with cyclical systems that include forest production.

INTELLECTUAL PROPERTY RIGHTS AND INDIGENOUS KNOWLEDGE: THE THREAT OF COMMODIFICATION

While biodiversity managers or development practitioners are only beginning to define a role for indigenous knowledge, its utility in another domain has been fully recognized and is being vigorously acted upon. Bio-prospecting, the quest for natural products to be exploited for commercial gain, is explicitly targeting traditional knowledge holders. In this arena, the pharmaceutical, agricultural and biotechnological industries have been particularly active. They recognize that the accumulated knowledge and traditional practices of indigenous communities are a powerful resource that can greatly facilitate the task of identifying useful new varieties of domestic plants or animals, isolating novel biological components, or developing innovative technologies and techniques. Recognition, however, has not automatically led to acknowledgement and the need to share benefits with the community is regularly overlooked.

The patenting of domestic plant varieties, traditional medical products and other biological resources whose identification and use are embedded in traditional knowledge has been a source of grave concern for developing countries and indigenous communities. By conferring upon foreign companies or individuals the exclusive right to exploit for commercial benefit certain inventions' that are in fact based upon indigenous knowledge, the patenting process transforms persons who do what they have always done into patent infringers. In one infamous case, the wound-healing capacity of turmeric, known and used in India for centuries, became a patented invention in the US. As a result, it became illegal for Indians residing in the US to use turmeric for this purpose. Similarly, a European patent on the fungicidal properties of the neem plant privatizes the botanical knowledge of Indian farmers who, for generations, have used this natural pesticide in their fields. In the end, both of these patents were revoked, but only after long and costly challenges mounted by the government of India (Dutfield, 1999). Similarly, the Bolivian National Association of Quinoa Producers has mounted a challenge against a US patent relating to a unique male sterile variety of the quinoa plant, a characteristic long known to Andean peasants and used by them to control the development of new hybrids. As Gari (1999, 6) astutely points out this patent does much more than just hijack indigenous knowledge for the eventual material benefit of a developed country. It also strengthens and spreads the Western paradigm of nature and science , by presenting knowledge pillaged from Bolivian peasants as the cutting edge of biotechnology.

Patents are only one of several legal instruments that constitute the current regime of intellectual property rights (IPRs). Others include trademark, copyright, geographical indication and plant variety rights. For indigenous knowledge holders, IPRs have been more often a source of problems, rather than solutions. Certainly they serve to protect the interests of companies that engage in bio-piracy, the unauthorized exploitation of biological resources and indigenous knowledge. A key debate today is whether contemporary IPR regimes can be adapted to also defend the interests of those who are custodians of indigenous knowledge.

To counter the granting of patents prejudicial to indigenous peoples, actions have been taken before the World Trade Organization under the agreement on trade-related aspects of intellectual property rights (TRIPS).

While providing a forum for overturning inappropriate patents, nothing in the TRIPS Agreement has been expressly designed for the protection of indigenous knowledge. Nevertheless, existing IPR arrangements may offer some viable options, and efforts are being made to explore these possibilities, including the development of sui generis (of its own kind) systems. The World Intellectual Property Rights Organization, for example, has recently created a commission on genetic resources, traditional knowledge and folklore, whose mandate includes the investigation of innovative measures to accommodate the exceptional characteristics of indigenous knowledge systems.

The challenge is a sizable one. IPRs have evolved within narrow socio-economic and political contexts. Designed to protect individuals whose inventions require safeguarding in view of their potential commercial value, they remain largely incompatible with indigenous knowledge, which is collectively owned; whose invention extends across generations; and whose raison d etre is not pro t, but ecological understanding and social meaning. Due to this incompatible nature, legal rights may have impacts quite other than those intended. By protecting select elements in isolation from the larger cultural context, they encourage the fragmentation of cultural systems. By designating knowledge owners, they may trigger social dissension between those recognized as proprietors and others who are excluded. Finally, as IPRs protect knowledge by setting rules for their commercial exploitation, ironically they may in the end merely facilitate the appropriation of traditional knowledge by the global marketplace.

RELATIONS OF POWER: KNOWLEDGE APPROPRIATION OR INDIGENOUS EMPOWERMENT?

The scienti c and development community views indigenous knowledge rst and foremost as a resource to be appropriated and exploited. Even scientists with the best of intentions may accelerate the demise of other knowledge systems by valorizing components resembling science and implicitly (or explicitly) casting dispersions on other elements that in science s view are mere superstition and belief. Such a process captures and instrumentalizes indigenous knowledge, strengthening the hand of those in positions of power at the expense of indigenous peoples.

This is not to argue against the exchange and sharing of knowledge between scienti c and indigenous systems. However, as Agrawal (1999) underlines, it would be irresponsible and a disservice to indigenous peoples to ignore the power relations that de ne such processes, and in particular, to fail to appreciate the implications of the severe power asymmetry between indigenous peoples and proponents of science.

To seek a way forward, it is important to come back to the questions of culture and worldview. For scientists, culture is a foreign element whose consideration falls outside the bounds of their profession (though they would probably agree to associate the cultural factor with the indigenous component of the equation). They are quite reluctant to admit that the culture of science is, in itself, a valid object of study. Cultural constructions such as the opposition of Nature (environment) and Culture (society), and the differentiation of rationality from spirituality, the empirical (science) versus the symbolic (religion), have provided science with its very foundations, and remain today an everyday reality of scienti c thought and practice. These tenets are such an integral part of the scienti c worldview that natural scientists are not aware of them as speci c cultural interpretations of the world. For them, they simply represent reality. Scienti c reality, however, differs from that lived by indigenous knowledge holders, whose conceptions of the world include pathways between natural and societal realms and whose spirituality infuses everyday objects and everyday acts.

In other words, there is no sound basis for deciding that one worldview offers a superior reference point for reality than another. We can of course arbitrarily choose and given science s institutional power, it is not surprising that the objective and rational scienti c method is repeatedly called upon to judge other knowledge systems. But it is important to recognize that this is a societal choice, not one defensible from any neutral or extra-cultural perspective. Consequently, the encounter between scienti c and indigenous knowledge must be understood as a meeting of cultures, with the cultural component as prominent in one camp as the other.

Full appreciation of this perspective alters our approach to articulating (a better term than integrating) scienti c and indigenous knowledge. Emphasis must be placed on leveling the playing eld and appreciating indigenous knowledge not as static sets of information to be conserved *ex situ* and integrated into science, but as dynamic components of contemporary indigenous societies and cultures. Accordingly, the protection of indigenous knowledge may better pass through pathways such as conserving indigenous language (as knowledge is encoded in language), ensuring knowledge transmission within the societies themselves, empowering indigenous societies so as to increase their control over processes of change, and ensuring continued access to the environments upon which their ways of life depend (*see* **Development and Global Environmental Change**, Volume 5).

International Environmental Law

M J Peterson
University of Massachusetts, Amherst, MA, USA

International environmental law is the branch of international law addressing human interactions with nature,

with particular focus on protecting the biosphere, including its subsystems, natural processes, and species diversity from serious harm caused by human activities and regulating the human use of natural resources. Its substantive and procedural principles, norms and rules are expressed in a growing number of global, regional, and bilateral treaties, declarations and action programs issued by international conferences and intergovernmental organizations, and emerging rules of customary international law. These specify goals towards which governments should strive, environmental standards they should incorporate into their cooperative and individual efforts to protect the environment, and certain procedures they should follow in cooperative and individual efforts to protect the environment from signi cant harm.

Because international environmental law only addresses states (acting through their governments), it forms only one part of the legal structure designed to promote greater environmental protection. The activities of individuals, households, groups, and private rms remain subject to the national legal system of the state where they act or of which they are a national. Thus, effective protection of the environment requires that international and national environmental law be aligned. This process has been promoted by the extensive borrowings of principles and norms between both levels, international programs that spread regulatory expertise and increase the administrative capacity of developing states, and the efforts of a highly active transnational environmental movement.

One institutional difference between national and international law makes developing, revising, and enforcing international law more complex: the international system lacks the central legislative, executive, and judicial bodies that maintain national legal systems. Development and implementation of international rules depend on a more complex process of bargaining and mutual in uencing between states equal in legal status as sovereigns but unequal in terms of size, wealth, and level of industrialization. This process is increasingly affected by popular pressures within states and the transnational activities of interest groups and social movements.

Both the general international law applying to all states and particular treaties negotiated between two or more states have long re ected concern about aspects of nature. Perceptions of the abundance of sh stocks in uenced positions in the 17th century debates between proponents and opponents of the principle of freedom of the seas. Sharing navigational and other uses of rivers and lakes straddling the territory of more than one state promoted development of a distinct law on international watercourses. Disease control, protection of plants, migratory birds, and animal species, distribution of shing rights and prevention of over shing on the high seas became the subjects of multilateral and bilateral treaties in the late 19th and early 20th centuries. Pollution at sea, particularly from oil tanker operations and waste dumping, transport of hazardous substances, radiological hazards from military and civilian uses of nuclear energy, and transboundary water and air pollution umes were added to the subjects of treaty making after World War II (Ruster et al., *1983; UNEP, 1990).*

Concerns about protecting nature or natural resources were gathered under the common heading of international environmental law, only after ecological worldviews highlighting the interconnection of natural systems and the deleterious consequences of their alteration by human conduct were diffused widely among governments during the preparations for and discussions at the 1972 United Nations (UN) Conference on the Human Environment (Stockholm Conference) (Schachter, 1991; Caldwell, 1998). The 1992 UN Conference on Environment and Development (Rio Conference), with its emphasis on the strong interconnections among environmental protection, economic development, and participatory governance at both national and international levels ensured that the integration of international environmental law with other branches of international law would be taken as seriously as its further development.

The process of developing international environmental law has been shaped by several particular characteristics of environmental issues. It also involves development or wider use of several procedural innovations in negotiating, revising, and implementing international agreements meant to speed those processes and adapt them more fully to contemporary needs. So far it has yielded considerable, though not complete, consensus on a set of overarching principles and policy norms to guide the handling of speci c environmental problems as well as an ever increasing set of global, regional, and bilateral agreements regarding a wide range of environmental problems.

THE SPECIAL CHARACTERISTICS OF ENVIRONMENTAL ISSUES

International environmental law is distinct from other branches of international law not because it is relatively new, but because international environmental issues have several distinct features that give international law-making and law application in that field a distinct character.

- Relatively large and persistent uncertainty about impacts of human action or inaction on the biosphere is the most important of these characteristics. This uncertainty is a compound of changing scientific understanding of natural biosystems, changing natural system responses to human-induced stresses, and changing degrees of human-induced stress as technology alters, global human population increases, and consumption patterns shift. Uncertainty is not unique to

environmental issues, but it has more sources and appears to operate within wider bounds than for other issues.

- Heavy reliance on expert advice, not just from scientists but also from engineers, resource managers, and economists, marks the formulation and implementation of regulatory decisions because of the breadth and pervasiveness of uncertainty. Many environmental problems are very subtle in their early stages, and their identification depends on the enhancement of human perceptual abilities provided by scientific instruments. Assessing alternate solutions generally involves fairly complex assessments of causal relations among multiple factors as well as comparative cost-benefit analyses.
- Lawmakers must consider impacts over a relatively long time horizon because of the timelags between introductions of new technology or other changes in human activity and alteration of natural systems in response.
- Ensuring national compliance with environmental commitments imposes heavy administrative burdens on governments since most of the activity creating the need for explicit environmental protection is undertaken by individuals, households, business firms, and other private entities rather than by government agencies or officials. In many respects, international environmental law is a set of mutually agreed mandates directing governments to develop and use their administrative capacities in particular ways.
- The activities regulated are characterized by widespread externalities: both the bad effects of neglecting the environment and the good effects of improving environmental protection extend beyond the property of the private entity involved and often beyond the territory of the state where the activity occurs. This means that the full costs or benefits are not borne or enjoyed by the private entity or even the country creating harms or providing benefits to others, with the result that law must often include incentive schemes or other mechanisms for inducing actors to take the full range of costs and benefits into account.

At the same time, international environmental law shares two significant characteristics with other branches of international law.

- Necessity for integration or coordination of rules with other branches of international law. Integration will be particularly strong with those other branches of international law regulating use of physical spaces (law of the sea, law of international watercourses) or the exploitation of resources (much of international economic law). The less extensive overlaps with human rights law and the law of warfare are also sufficient to pose coordination problems, requiring similar processes of balancing the values promoted by the different branches of international law and ensuring that their rules are compatible with each other.
- Entanglement in wider debates about the future structuring of international, national, and local governance. International law will be affected by the results of current debate concerning whether the world will remain divided into some 200 states claiming sovereignty over their individual territories and populations. On the one side are governments and publics resistant to giving up sovereignty, whether by making promises to other states or by transferring significant governing authority to an intergovernmental organization like the UN Environmental Programme or a supranational organization like the European Union. These fears are particularly strong in developing states, where any significant centralization of authority is seen as an effort by the industrial states to maintain dominance of the global economy. The fears have been shared by segments of public opinion on both populist or nationalist right and socialist left in many of the industrial states, who see the process as one of yielding to distant and unaccountable elites. On the other side are two strong currents of opinion within the environmentalist movement regarding national sovereignty as an anachronism: one because it stands in the way of the greater global centralization needed to ensure a sustainable world, and the other because it stands in the way of shifting governance to a smaller scale promoting more sustainable lifestyles through application of local knowledge and face-to-face mutual accountability. Similar debates have raged in the fields of international human rights and international trade. All three have intensified as critics have demanded that the World Trade Organization pay more attention to environmental and labor issues. These critics see the interrelated debates as amounting to a choice between globalization on terms decided by a multinational corporation-dominated elite, and participatory political institutions seeking creation of a just world by regulating markets.

PROCEDURAL INNOVATIONS

The widespread and growing sense of urgency in addressing environmental problems has encouraged government officials, legal advisers, and diplomats involved in developing international environmental law to adopt a number of procedural innovations. These are aimed at speeding up the traditionally slow processes of negotiating multilateral treaties

or developing new rules of customary international law, accommodating the need for a wide range of information in decision-making, and providing greater mutual pressure for implementing agreed policy measures than has traditionally existed at the international level (see, e.g., Brown-Weiss *et al.*, 1998; Kiss and Shelton, 1999; Victor *et al.*, 1998 for greater detail.)

Framework Treaty Protocol Form

The older practice of distinguishing between the main portion of a treaty and annexes, protocols, or schedules containing detailed rules that can be modified as needed through an expedited amendment process, has been developed more fully in the framework treaty-protocol form used in many of the major global environmental treaties negotiated since 1985 (Kiss, 1993). The framework treaty identifies the environmental problem to be addressed and specifies procedures for the meetings of the parties that determine the regulatory measures to be adopted, monitor their implementation by participating national governments, and assess the state of the natural systems involved and the efficacy of the regulatory measures with an eye to their revision. The protocols stipulate the particular regulatory measures selected and may also elaborate on the procedures for joint decision, implementation review, and results assessment. Most protocols are developed later as governments gain better understanding of the problem, develop clearer conceptions of possible solutions, and work out the political deals necessary to assure participation by enough governments to provide good chances of success. By making the protocols relatively easy to add to, delete, or amend (whether by delegating that task to the meeting of the parties or by using rules specifying a deadline for opting out), they can be revised as new information or new understanding of policy options develops. Governments thus take an incremental approach to regulation, rather than attempting to work out all the details in a single negotiation, as attempted at the Third UN Conference on the Law of the Sea in 1973–1982 (*see* Ozone Layer: Vienna Convention and the Montreal Protocol, Volume 4; United Nations Framework Convention on Climate Change and Kyoto Protocol, Volume 4).

Periodic Situation Assessment

All law-making and law revision rests on assessments suggesting that a problem is sufficiently important to warrant attention, can be solved or abated through consciously directed human action, and will likely be solved or abated by adopting a particular set of regulatory measures. International environmental law has formalized situation-specific assessments to an unusual degree because of the need for scientific investigation to demonstrate the existence and causes of an environmental problem and the complexities of coping with uncertainty as regulatory responses are formulated. Scientific assessments of the dimensions of the environmental issue at hand often precede or form an important part of the initial negotiation of an environmental treaty. The major environmental treaties also provide for periodic assessment of both the state of the natural environment and of relevant technology or regulatory measures through parallel scientific and technical advisory committees. These periodic assessments create what Sand (1996, 792) calls a pre-ordained learning process in which governments are kept informed of changes in or newly developed knowledge about natural systems, technology, and the efficacy of regulatory responses.

Ongoing Implementation Review

Since the perceived successes of the effort to protect the ozone layer, environmental treaties have included: provisions for reporting policy actions and relevant statistics regarding production or emission of pollutants, joint review of efforts in a multilateral implementation committee separate from but reporting to the *Conference of the Parties* (COP) (*see* Conference of Parties, Volume 4), and dispute resolution. The considerable success of non-adversarial approaches to encouraging better implementation relying on consultation, persuasion, and provision of assistance for administrative capacity building have inspired debate among international lawyers and political scientists regarding the relative importance of compliance – promotion and a more traditional enforcement approach in promoting compliance with treaty commitments (Chayes and Chayes, 1995 and Downs *et al.*, 1996 provide clear statements of the contrasting views.)

Extensive Use of Soft Law

Building on the traditional international law distinction between the legally non-binding *voeux* or recommendations of international conferences and the legally binding obligations of written or oral promises made to other governments, international lawyers have developed a new concept, *soft law*. It covers statements of desired goals and agreed policy directions forming a political or moral commitment stronger than summarized in the traditional understanding of recommendations but still falling short of legal obligation (Dupuy, 1992). Most soft law, like the Stockholm Declaration (1972) and Rio Declarations (1992) and Agenda 21 (1992), is the product of agreed statements adopted at international conferences, but some treaty provisions may also express soft law commitments. The use of soft law is particularly extensive in international environmental law because of the widespread belief that environmental problems must be addressed more

rapidly than the traditional forms of treaty-making allow. Advocates of soft law approaches claim that they help overcome the hesitations induced by uncertainty by allowing governments to make preliminary commitments that can be adjusted later and permit negotiations to get beyond least common-denominator policy choices. Critics worry that heavy reliance on soft law encourages papering over disagreements and creates confusion about what governments have or have not committed themselves to do, making it harder for others to call them to account for lagging in implementation.

Explicit Opening of the International Law-Making Process to Participation by Non-state Entities

Domestic democratization in many parts of the world and the vast increase in transnational activism by organized social movements have combined to increase demands for broader participation in the formulation and revision of international environmental law and the monitoring of governments compliance with it. Environmental groups have had considerable success lobbying international conferences, inspiring similar activity by other groups while the scienti c and technological assessment panels generally consist of persons drawn from the scienti c, industry, labor, and environmental communities as well as government bureaucracies (*see* **Integrated Assessment, De nition of**, Volume 4; **ULYSSES (Urban Lifestyles, Sustainability, and Integrated Environmental Assessment)**, Volume 4; **Post-normal Science**, Volume 5).

EMERGING PRINCIPLES OF INTERNATIONAL ENVIRONMENTAL LAW

Each branch of international law contains certain broad principles that express a reason to prefer or avoid a particular result or behavior. These principles do not specify how to act in particular situations; rather, they orient action by indicating the goals and other considerations to be emphasized when deciding how to act. The struggle to de ne these principles has been intense because reorienting international law to take environmental protection more seriously has required rede ning the central international legal principle of state sovereignty to highlight responsibilities to protect the natural environment. Some of this rede nition was accomplished by expanding traditional doctrines of good neighborliness and abuse of rights, and reinterpreting the traditional legal maxim *sic utere tuo ut alienum non laedas* (use what is yours in a manner that does not harm others). While successfully expanding state responsibilities towards other states, these adaptations of traditional doctrine fell short from an ecological point of view because they failed to provide a basis for obligation to protect nature, natural processes, or natural resources when the environmental impact of human activity is con ned within the territory, airspace, or maritime jurisdiction of a single state. Efforts to establish that broader obligation have been troubled by two persistent disagreements. The rst involves different emphases on the balance to be drawn between the generally accepted principle of permanent sovereignty over natural resources and wealth, highlighting the right of each state to adopt its own program of economic organization and regulation, with the emerging rules of environmental protection. The second stems from disagreements between those who believe that the basic purpose of international environmental law is to enhance human existence by promoting living within the limits of nature and those believing that its basic purpose is to protect the intrinsic value of the biosphere. These have occasionally inspired strong controversy on particular policy questions, but have played out more generally in the reluctance of many governments to accept the notion of an environmental right. Governments of developing states in particular have worried that accepting such a right might erode the also controversial right to development that they have been advocating for many years.

Recent intergovernmental declarations, multilateral treaties, and controversies regarding their application in particular situations have yielded considerable convergence on a set of principles of international environmental law establishing obligations to weigh protection of the environment heavily in decision-making and action. Though the exact legal status of some principles remains in doubt, and their generality often leads to controversy about their application in speci c situations, these broad principles provide the basic orienting statements of current international environmental law.

- The principle that states must ensure that activities within their jurisdiction or control do not harm the environment in other states or global common areas. This principle has the strongest connection with traditional international law principles concerning the rights and duties of sovereign states, as well as the clearest expression in international environmental declarations and treaties.
- The principle of sustainable development. This is sometimes treated as part of international environmental law and sometimes as a principle mandating the closer integration of international environmental and international economic law (e.g., Sands, 1996). It was rst formulated in its current terms by the UN World Commission on Environment and Development (1987) (Bruntland Commission), which de ned it as development that meets the needs of the present without compromising the ability of future generations to meet their own needs . The International Court of Justice stopped short of calling sustainable development a legal principle in the Gabcikovo-Nagymaros Case

(1998), but did characterize it as an objective that states are legally obligated to take into account in decisions on economic policy and particular projects. Third World governments have been particularly insistent that the principle means that economic development will not be subordinated to environmental concerns; environmentalists have been equally insistent that it means environmental protection cannot be subordinated to economic development. Yet this mandate to balance and serve both concerns provides little guidance for striking that balance in particular situations. It is clearest on questions of time horizon, strongly favoring adoption of longer-term perspectives in decision-making.

- The principle of intergenerational equity. This is closely linked with that of sustainable development through reciprocal reference. Sustainability suggests maintaining natural systems over time spans longer than a single generation, while intergenerational equity is defined in terms of acting in such a way that future generations have as many alternatives in use of ecosystems and resources as are available to the current generation. The notion that future generations have legally enforceable rights has inspired considerable controversy, but there is no serious dissent from the underlying claim that governments and other actors must shift away from a fixation on the immediate future (whether this be the next profit or loss statement for businesses or the next election for governments) if they are to provide adequate environmental protection. The controversy about how to do so is considerable, and fuelled by the way longer-term thinking rubs against well entrenched economic (the discounting of future returns) and political (constituencies are those persons alive today) thinking.
- The principle of common concern. This articulates the belief that environmental problems are the concern of all states and is an effort to institutionalize two standards of conduct. The first is that environmental protection, like more traditional duties to provide effective administration of territory or newer duties to respect human rights, is one of the standard obligations of sovereigns, one of the duties that, paired with a set of rights to political independence, territorial integrity, and nonintervention by other states, are integral to the status of sovereign. Applied strictly, the principle means that failure to adopt adequate domestic environmental law is itself a violation of international obligations, a reading that governments have been reluctant to take very far. The second is that obligations deriving from customary or treaty-based international environmental law are owed to the international community as a whole, not simply to the state or states directly harmed by failures to protect the environment. Ambitious efforts to establish all failures to comply with an environmental agreement as violations *erga omnes* (matters about which any state may complain) still inspire controversy, but the principle has supported the institutionalization of the right to point out implementation failures by other states on a problem-by-problem basis in the new system of ongoing implementation review. This principle is reinforced by the traditional principles of good neighborliness and cooperation among states, which are not unique to international environmental law though they have environmental expressions.
- The related principle of common but differentiated responsibility. This expresses the general terms of ongoing bargaining between developing states and industrial states regarding who will provide what part of the effort and financial resources needed for international environmental cooperation. It rests on moral claims that the industrial states' greater role in causing environmental problems (by industrializing without the burden of environmental protection measures and continuing patterns of profligate resource consumption and waste generation) plus their greater ability to redress them (through possession of more advanced technology and greater financial resources) mean that they should bear most of the burden of environmental protection. In some respects the principle can be seen as a generalized interstate expression of the *polluter pays principal* (*see* PPP (Polluter Pay Principle), Volume 4). Though triggering intense bargaining whenever invoked in a particular environmental negotiation, the principle has promoted use of several methods of differentiating obligations in recent environmental treaties. These include: allowing grace periods that give developing countries more time to meet emission standards; defining different baselines that allow developing countries to increase pollution levels to accommodate a measure of economic growth; providing financial assistance; and even accepting that developing country implementation is contingent on provision of financial assistance. However, the current emphasis on a binary categorical distinction between industrial and developing states will need modification in coming years, partly because at least some developing countries are or soon will be significant contributors to pollution problems and partly because the distinction ignores the highly varied situations and economic performances of developing states. Shifting from the current focus on differential norms and rules distinguishing amongst named groups of states to a focus on contextual norms and rules based on differences in situation (Magraw, 1990) would permit better accommodation to the environmental implications of differences in size, geography, climate,

and economic circumstances of different countries (*see* Common but Differentiated Responsibility Principle (Stockholm/Rio), Volume 4).

POLICY NORMS (PRINCIPLES) OF INTERNATIONAL ENVIRONMENTAL LAW

International environmental law also includes a number of policy norms that provide guidance regarding the forms or objectives of regulatory measures to be adopted at the international and national levels. Most of these policy norms (frequently called *principles* to emphasize their importance, a reflection of the lack of standardized terminology for the various types of legal prescription in international law) originated in the national law of a particular state, but were adopted more widely as their usefulness in promoting more effective environmental protection was perceived. The policy norms of international environmental law thus serve as a summary of and mandate to adopt what governments agree are the best national regulatory practices. More specific guidance regarding the precise sort of regulatory measure to adopt (direct control, emissions standards, ambient standards, product standards, process standards, recycling or return rules) and the sort of related economic incentive schemes to adopt is specified on a problem-by-problem basis in the growing body of multilateral, regional, and bilateral treaties and codes of conduct developed through intergovernmental organizations.

- The polluter pays principle (norm) which asserts that the costs of protecting the environment should be borne by those whose activities pose dangers to it. It developed primarily in national discussions of how to pay for cleaning up or avoiding pollution, and rests on rational choice assumptions that changing incentives by altering the costs of activity or inactivity will trigger changes in behavior. It was developed in the national environmental law of several industrial states to justify imposition of pollution taxes, direct regulations requiring polluters to install specified pollution abatement equipment, and to signal that the days of free use of the environment as a sink for all manner and quantities of waste were at an end. It serves similar functions at the international level.
- The precautionary principle, initially elaborated primarily in West Germany, endorsed in Principle 15 of the Rio Declaration, and incorporated into several later multilateral treaties, mandates that action be taken to avoid long-term consequences of some present-day activity when there is significant uncertainty about the extent or material causes of damage from an activity. Traditionally such uncertainty was used as an argument for deferring the imposition of limits on an activity. The precautionary principle shifts the terms of argument by placing the burden of proof that an activity is safe on those who would undertake an activity rather than on those who would impose regulations. In the strictest readings, precaution would require regulators to allow only those activities posing no danger of harm to the environment. Implementing the precautionary norm raises three interrelated controversies: 1) what standard of proof should guide assessments of anticipated environmental effects, 2) what constitutes a harm, 3) what constitutes a danger of harm. Defining danger requires answering two questions: how much harm could result from an activity and what is the probability of that harm occurring. Disagreement on all these matters has made the norm controversial among those who regard it as requiring elaboration of a generally applicable standard. The level of disagreement declines when the norm is understood as mandating an approach to policy that favors erring on the side of caution in authorizing or regulating an activity (*see* Precautionary Principle, Volume 4).
- The norm that governments should promote use of environmentally benign technologies. It first developed in Western Europe but has won wide endorsement. Any controversy it inspired is focused on how far technology choices may be based on the comparative costs of adopting different technologies, leading to a range of formulations ranging from *best available technology* (BAT) to *best available technology not entailing excessive costs* (BATNEEC). Developing county governments have invoked the norm to support their claims that they should enjoy access to technologies on more favorable terms than currently prevail in international commerce.
- The norm of prior assessment of environmental impacts of proposed activities, first developed in the USA and later adopted in other parts of the world. It supplements the precautionary principle by requiring serious efforts to understand environmental consequences before major activities proceed, and has been linked to efforts to develop more transparent and accountable government through arguments that it should include opportunities for comment from the general public.
- The prior notification norm, which is both a continuation and an extension of international rules with a long history. Multilateral treaties regarding particularly hazardous activities, such as maritime transport of nuclear materials, operation of nuclear power plants, transport of toxic or hazardous substances, and incidents of oil pollution at sea, have long included obligations of notification. Most of these obligations involve notification of accidents likely to have effects abroad; a few

also mandate the sharing of data regarding hazardous or toxic chemicals or the securing of prior consent from the government of another state before shipments of certain substances to addressees on its territory occur.

- The public information norm, which is well developed in the domestic legal systems of western industrial states, but only beginning to be defined in international law. It is given particularly strong emphasis by those seeking to increase the direct participation of non-governmental organizations and other non-state entities in environmental governance, but arriving at a consensus international definition is difficult because of the variety of national practices on the subject (*see* Governance and International Management, Volume 5).

ISEW (Index of Sustainable Economic Welfare) and GPI (Genuine Progress Indicator)

Aggregate economic indicators, such as gross domestic product (GDP), are derived from the system of national accounts (SNAs) that are now standardized across nations. The indicators measure the rate of market and government activity of an economy and are used for comparisons over time and between nations. Economic goods and services produced in households, in subsistence economies, and through the contribution of non-market environmental services are not included in the SNAs and hence are not included in the aggregate indicators. The missing information also results in misrepresentations and misinterpretations of the market data that are included (*see* Ecological Economics, Volume 5). These concerns have led to the development of expanded accounting systems and alternative indicators, the most famous of which are the ISEW and its evolutionary offshoot, the GPI.

Economists frequently argue that it is inappropriate to represent GDP *per capita*, or other indices derived from the SNA, as measures of well-being, or even economic

well-being. Nonetheless, economists and others frequently use these terms in exactly this way. In light of this, many have argued that reasonable aggregate measures of well-being need to be developed. The ISEW was conceived by Herman Daly and John Cobb and developed by Clifford Cobb (Daly *et al.*, 1989) to be a superior indicator of economic well-being. They also hoped that the index would indicate what the sustainable level of well-being was. The ISEW corrects, at least partially, for the absence of the household and environmental sectors in the SNA. It also takes the additional step of addressing equity, arguing that adding $1000 to the annual consumption of a rich person does not improve welfare nearly as much as it would for a poor person. Further, the ISEW does not include government expenditures on national defense, health care, prisons, etc., because they are largely partial corrections for problems that have grown worse over time. An ISEW has been calculated for many European countries.

The GPI in the US evolved from the ISEW and is being promoted by a non-governmental organization, *Rede ning Progress*. GDP *per capita* in the US nearly tripled during the second half of the 20th century. The GPI shows well-being increasing more modestly from 1950 into the early 1970s and then drifting downward. GDP and ISEW show similar patterns in Europe. The ISEW, GPI, and other alternative indicators have played a modest role in environmental debates about economic growth in developed countries and have prodded the World Bank (Lutz, 1993) and national governments (Nordhaus and Kokkelenberg, 1999) to consider amending the SNAs. However, alternative indicators have yet to be incorporated in the debate over North–South equity and global environmental change.

Islam and the Environment

Fazlun M Khalid

Islamic Foundation for Ecology and Environmental Sciences, Birmingham, UK

It has often been observed that Islam cannot ordinarily be described as a religion and that it prescribes a way of life that goes beyond the performance of rituals. The word for religion (d¯n) is found in the Qur'¯an (anglicized spelling: Koran; this is Islam's sacred text on which much of this essay is based). The word d¯n, which appears in 90 different places, often in contexts that place it outside the purely ritual. D¯n in essence describes an integrated code of behavior which deals with personal hygiene, at one end of the spectrum, to our relationships with the natural order at the other. It provides a holistic approach to existence, it does not differentiate between the sacred and the secular and neither does it place a distinction between the world of mankind and the world of nature.

However, this Islamic mode of expression is now severely attenuated, having been swept aside by the forces of history, like the other older traditions, into a domain which treats the natural world exclusively as an exploitable resource. As what we now understand by modernity advanced, as the secular ethic progressively seeped into the Muslim psyche and as industrial development, economic indicators and consumerism became the governing parameters of society, there has been a corresponding erosion of the Muslim perception of the holistic and a withering of its understanding of the sacred nexus between the human community and the rest of the natural order: The creation of the heavens and the earth is far greater than the creation of mankind. But most of mankind do not know it (Qur ¯an 40:56).

For these and other reasons, Muslims in various parts of the world have in recent times sought the reversal of these trends through the re-establishment of Islamic governance based on the Islamic code known as the Shar¯ ah. Deeply embedded in its matrix are detailed and sometimes complex rules, which lay down the basis for Islamic environmental practice. Islamic jurisprudence contains regulations concerning the conservation and allocation of scarce water resources; it has rules for the conservation of land with special zones of graded use; it has special rules for the establishment of rangelands, wetlands, green belts and also wildlife protection and conservation. Much of the traditional institutions and laws associated with sound environmental practice in Islam have now fallen into disuse.

*Although the re-establishment of Islamic governance is an aspiration held by an increasing number of Muslims, there is now a growing movement amongst them, led by thinkers like Seyyed Hossein Nasr (*see **Nasr, Seyyed Hossein**, Volume 5*), who place an immediate priority in dealing with*

the intractable problems that the human race is creating for itself by overexploiting and degrading the planet beyond repair. Credit is due to Seyyed Hossein Nasr for almost single handedly rekindling the consciousness of not only Muslims, but of adherents of other traditions, to the dimension we have come to describe as faith and nature. His first exposition on this subject was a series of lectures in May 1966, delivered at the invitation of the University of Chicago, which was eventually published (Hossein, 1968). He has written voluminously on this theme since then; see, for example, Hossein, 1996. For Muslims this crisis calls for a fresh evaluation of the teachings of Islam and its practice in the present globalized order.

A GLANCE AT THE BASICS

Islam is the name of the religion discussed in this contribution. A Muslim (called a Musselman in the 18th century) is a follower of Islam. The word Islam literally means submission or surrender, and a Muslim is one who surrenders his will to the will of God. A Muslim country is one in which the majority of people are Muslims – there are about 60 such countries in the world.

The roots of Islamic environmental practice are to be found in the Qur'ān and the guidance (sunnāh) of Prophet Muhammad. Prophet Muhammad is the Prophet of Islam and is usually referred to by Muslims as the Messenger of God (Rasūlullāh). He was born in 570 AD in Mecca and died in 632 in Medina, in what is now Saudi Arabia. Over the centuries, Islamic practice has been elaborated by a succession of scholars and jurists responding to real problems experienced by the growing community of Muslims in various parts of the world.

The Islamic worldview is based on the belief in the existence of an all powerful creator who is the same God (Allāh in Arabic) of the other monotheistic faiths, Judaism and Christianity. Muslims learn from the Qur'ān that God created the universe and every single atom and molecule it contains and that the laws of creation include the elements of order, balance and proportion: He created everything and determined it most exactly (25:2) and It is He Who appointed the sun to give radiance and the moon to give light, assigning it in phases ••• Allāh did not create these things except with truth. We make the signs clear for people who know (10:5).

What may be described as the Islamic creed has three aspects. The first is the core value system that Islam establishes, which is islām itself and in this context is taken to mean submission. The second is faith (imān) and the third is good personal conduct (ihsān) traditionally described as righteousness or piety.

Islam, in its verb context, is elaborated in what is commonly described as the five pillars. The first of these is a two-part declaration (shahadā) bearing witness that there is no God but God and that Muhammad is the Messenger of God; the second is the performance of the five daily prayers (salāt); the third is the annual payment of a specific tax (zakāt); the fourth is to fast during the month of Ramadhan (sawm); the fifth is to make the pilgrimage (hāj) to Mecca at least once in a lifetime for those who have the means to do it.

Imān was described by the Prophet Muhammad as knowing with the heart, voicing with the tongue and expressing with the body. This requires the profession of faith in God, His angels, His books, His messengers, the final day and acceptance that life in all its expressions emanates from the divine source.

Ihsān is described as the act of worshipping Allāh as if you see Him, knowing that even if you do not see Him, He sees you. This goes much beyond the ritual prayers; and every good action performed by a believer is seen as an act of worship. This is commonly expressed by Muslims as doing what is pleasing to Allāh, who is ever present, ever watchful.

Taken as a whole as it is intended to be, caring for planet Earth, our only home, is integrated within the framework of this value system. This is then an everyday concern for the Muslim, which the Qur'ān reminds him by saying, We have not omitted anything from the Book (6:39) and He said Our Lord is He Who gives each thing its created form and then guides it' (20:49). We will now look at how this is reflected in daily life.

THE ETHICAL DIMENSION

One of the stories often told by Muslims concerning the environment is the instruction by Abu Bakr, the first Caliph (Khalif) of Islam to his armies. In addition to telling them not to harm women, children and the infirm, he ordered them not to harm animals, destroy crops or cut down trees. There were two elements present in this decree: the first, to establish justice even as the Muslim armies fought, and the second, to recognize the value of nature. It should also be noted that the environment was not an issue or subject for separate treatment in life as it flowed onwards in both war and peace. The human condition was never separated from the natural order. It was a matter to be reckoned with at every moment of existence like the very air we take into our lungs.

Abu Bakr was the first of four rightly guided caliphs who succeeded the Prophet after his death. They were known as such because of the lengths to which they went to incorporate the instructions in the Qur'ān and the Prophet's example into their rule. The rule of the rightly guided caliphs lasted from 632 to 661 (AD) and became the time, including the time of the Prophet, which all Muslims to this day seek to emulate. In attempting to reproduce the Prophetic model what the rightly guided

caliphs did was to set a pattern that would evolve into the matrix that formed the basis of the Islamic legal system known as the Shar¯ah and which very soon came to circumscribe Muslim life. The word Shar¯ah has an interesting etymology with strong environmental connotations. It means a way or path in Arabic and its derivation refers to the beaten track by which wild animals come to drink at their watering places. It is the road that leads to where the waters of life flow inexhaustibly (Eaton, 1994; 180).

As Muslim populations grew and expanded territorially, their requirements in government became increasingly complex and the Shar¯ah accordingly became more sophisticated. To the Qur'ān and Sunnah were added two other elements: the consensus (ijmā) of scholar jurists and the process of reasoning by analogy (qiyās). Islamic law (fiqh) evolved out of this process and there are two other traditional instruments which were incorporated into this system and which could usefully serve the purpose of formulating environmental law in the Muslim world today. The first of these is interpretation in context (ijtihād) and the second is custom and practice (urf wa adāt).

The Shar¯ah expanded and evolved within this framework to set defining standards for Muslim behavior within the divine decrees of the Qur'ān, including *inter alia* family law, civil law, commercial law and environmental law. From the time of the Prophet, law has taken precedence over theology; this is stated to be the case because Islam's concern is about humankind and its relationship with the rest of creation, beginning, of course, with itself. The law is about defining these relationships and the following are examples of how the Qur'ān sees it (4:134).

> You who have imān (faith); be upholders of justice, bearing witness for Allāh alone, even against yourselves or your parents and relatives. Whether they are rich or poor, Allāh is able to look after them. Do not follow your own desires and deviate from the truth. If you twist and turn away, Allāh is aware of what you do

Truth takes precedence over love, even love for one's parents, and love is known habitually to conceal the truth. There is no compromise with truth and justice,

> so call and go straight as you have been ordered to. Do not follow their whims and desires but say, I have imān (faith), in a book sent down by Allāh and I am ordered to be just between you ••• (42:13)

The Qur'ān also asks us to be just to our natural surroundings, We did not create the heavens and earth and everything between them, except with truth (15:85).

Like the Muslims who had succeeded the Prophet and had attempted to give expression to the divine decree, the scholar jurists approached this matter with great diligence and formulated an ethical base derived from the imperatives laid down in the Qur'ān. These imperatives come under numerous headings but they could be distilled into just three categories for our purposes, bearing in mind that public good (al masalih al mursalah) is the ultimate objective (Doi, 1984). Muslims are to do what is right, forbid what is wrong and act with moderation at all times: let there be a community among you who call to the good, and enjoin the right and forbid wrong. They are the ones who have success (3:104). The Qur'ān again uses an environmental theme in exhorting humankind to be moderate; (6:142):

> it is He who produces gardens, both cultivated and wild, and palm trees and crops of diverse kinds and olives and pomegranates both similar and dissimilar. Eat of their fruits when they bear fruit and pay their dues on the day of their harvest, and do not be profligate. He does not love the profligate.

The Shar¯ah also evolved within the guidelines set by three principles agreed upon by scholar jurists over the centuries. They are:

1. the interest of the community takes precedence over the interests of the individual;
2. relieving hardship takes precedence over promoting benefit;
3. a bigger loss cannot be prescribed to alleviate a smaller loss and a bigger benefit takes precedence over a smaller one. Conversely a smaller harm can be prescribed to avoid a bigger harm and a smaller benefit can be dispensed with in preference to a bigger one.

THE NATURAL ORDER IN ISLAM

As the Islamic tapestry unfolded in its expression over the centuries, we discover that there are no references to the environment, as we understand it today. The word *nature*, which is an abstraction, cannot be found in the Qur'ān and the closest modern Arabic usage is the word b¯'a which connotes a habitat or a surrounding. The word nature will continue to be used in this essay for linguistic convenience. For a further explanation on terminology, see Khalid (1999). The Qur'ān speaks of creation (khalq) and it contains two hundred and sixty one verses where this word is used in its various grammatical forms derived from the root kh l q. These verses contain references to the human world; to the natural world of the Earth, from trees to turtles, from fish to fowl; and to the sun, stars and skies. The very first revelation of the Qur'ān to the Messenger used this word in its verb form to dramatic effect, Recite in the name of your Lord who created, created man from clots of blood (96:1). Creation is the fabric into which the tapestry of life is worked.

Creation or nature is referred to as the signs (āyāt) of Allāh and this is also the name given to the verses of the Qur'ān. Āyāt' means signs, symbols or proof of the divine.

As the Qur'ān is proof of Allāh so likewise is His creation. The Qur'ān also speaks of signs within the self and as Nasr (1993) explains,

> ••• Muslim sages referred to the cosmic or ontological Qur'ān ••• they saw upon the face of every creature letters and words from the cosmic Qur'ān ••• they remained fully aware of the fact that the Qur'ān refers to phenomena of nature and events within the soul of man as āyāt ••• for them forms of nature were literally āyāt Allāh.

As the Qur'ān says, there are certainly signs in the earth for people with certainty; and in yourselves. Do you not then see? (51:20, 21).

Writing from another perspective, Faruqi and Faruqi (1986) say:

> Its (nature's) goodness is derived from that of the divine purpose. For the Muslim, nature is ni'māh, a blessed gift of Allāh's bounty ••• to transform in any way with the aim of achieving ethical value ••• Since nature is Allāh's work, His āyāt or signs, and the instrument of His purpose which is absolute good, nature enjoys in the Muslim's eye a tremendous dignity.

The Qur'ān says about these matters (16:65–69):

> Allah sends down water from the sky and by it brings the dead earth back to life. There is certainly a Sign in that for people who hear. There is instruction for you in cattle. From the contents of their bellies, from between dung and blood, We give you pure milk to drink, easy for drinkers to swallow. And from the fruit of the date palm and the grapevine you derive both intoxicants and wholesome provision. There is certainly a Sign in that for people who use their intellect. Your Lord revealed to the bees: Build dwellings in the mountains and the trees, and also in the structures which men erect. Then eat from every kind of fruit and travel the paths of your Lord, which have been made easy for you to follow'. From inside them comes a drink of varying colours, containing healing for mankind. There is certainly a Sign in that for people who reflect.

The universe we inhabit is a sign of God's creation as is the environment of our innermost selves. They both emanate from the One Source and are bonded by only one purpose, which is to serve the divine will. This bonding of the cosmic to the subatomic is the deep ecology of Islam but it is not a relationship of equals as we can see in the hierarchy of the food chain dominated by Man. Whilst the primary relationship is that between the Creator and the rest of His creation, the Creator Himself determined a subsidiary one, that between Man and the rest of His creation which the Qur'ān defines as follows: It is He Who created everything on the earth for you ••• (2:28); We did not create heaven and earth and everything between them as a game ••• (21:16); We did not create heaven and earth and everything between them to no purpose (38:26); ••• He wanted to test you regarding what has come to you ••• (5:48).

The Qur'ānic view holds that everything on the earth was created for humankind. It was God's gift (ni'mah) to us, but a gift with conditions nevertheless and it is decidedly not something that one runs and plays with. The earth then is a testing ground of the human species. The tests are a measure of our acts of worship (ihsan) in its broadest sense. That is living in a way that is pleasing to Allāh, striving in everything we do to maintain the harmony of our inner and outer environments.

As our interaction with the environment evolved, it manifested itself in a range of rules and institutions. As the Muslim community expanded out of its sparse desert environment, it was confronted by many challenges, one of which was relative abundance. This brought about other problems like over exploitation and waste. Muslims applied themselves to these problems assiduously and it would be salutary to look at this legacy. For more information on this subject see Bagader *et al.* (1994); Llewellyn (1992); Dien (2000). The following is a brief summary of how the Shari'ah developed in this area over the past 1400 years.

Legislative Principles

1. Allāh is the sole owner of the earth and everything in it. People hold land on usufruct that is, for its utility value only. There is a restricted right to public property.
2. Abuse of rights is prohibited and penalized.
3. There are rights to the bene ts derived from natural resources held in common.
4. Scarce resource utilization is controlled.
5. The common welfare is protected.
6. Bene ts are protected and detriments are either reduced or eliminated.

Institutions

1. People who reclaim or revive land (ihyā al māwāt) have a right to its ownership.
2. Land grants (iqtā) may be made by the state for reclamation and development.
3. Land may be leased (ijārā) for its usufruct by the state for its reclamation and development.
4. Special reserves (h¯mā) may be established by the state for use as conservation zones.
5. The state may establish inviolable zones (al-har¯m) where use is prohibited or restricted. Every settlement has a right to create such zones managed by the people and where use is severely restricted. Additionally, it is permitted to establish these zones adjacent to sources of water and other utilities like roads and places of public resort.
6. Makkāh and Mad¯nah are known as the two inviolable sanctuaries (al-haramain) where trees cannot be cut down and animals are protected from harm within their boundaries. They serve as examples of best practice.

7. Charitable endowments (awqāf) may be established with specific conservation objectives.

Enforcement

The primary duty of the Islamic state is to promote the good and forbid wrong doing. As part of these functions, it has the mandate to protect land and natural resources from abuse and misuse. From its earliest years the Islamic state established an agency known as the hisbā whose specific task was to protect the people through promoting the establishment of good and forbidding wrong-doing. This agency was headed by a learned jurist (muhtasib) who functioned like a chief inspector of weights and measures and chief public health officer rolled into one. He was also responsible, among other similar duties, for the proper functioning of the h¯mā and al har¯m zones and he acted as what one might describe as an environmental inspectorate.

The development and application of these principles and institutions have seen a decline over the past two centuries, as another worldview based on the exploitation of natural resources for profit gradually overtook this model. We are experiencing the consequences of this now. However, there are clear indications as to how this Islamic heritage has been and could again be put to good use in the modern context.

AN EMERGING RESPONSE

The Muslim world was gradually co-opted into the new world order by force of arms and by force of economics. The first is history and the second present day reality and what the Muslims lost in between these twin processes was the sap of Islam and their unique way of perceiving the universe. For Muslims, their *d¯n* is a whole, an organic reality, where every element has a function as a part of this whole. For example, Islam law does not make sense without the ethical dimension of the divine revelation. Law in the West is amoral. It deals with human ends for human purposes. The Muslim idea of the highest form of civilization is that it is the one that is pleasing to Allah. In today's Western-dominated global order of which Muslims are a part, conspicuous consumption has become the highest imperative. Muslim nation states of which there are now about 60, are willing co-optees to this consumer ethic.

These are however, superficial considerations; and deep in the interface between Islam and the West are two irreconcilable factors that call for some examination. The first is the matter of existence itself and how it is to be defined and the second is the matter concerning money and how it is to be used.

The traditional worldview, which includes that of the West, was challenged by what we have come to know as the Enlightenment (*see* **Enlightenment Project**, Volume 5), having its origins in 16th century Europe. These events are usually seen as a time in which science began its ascendancy over religion. Tarnas (1996) observes that this movement achieved its maturity in the 19th century, finally resulting in a radical shift of psychological alliance from the divine to humankind. Descartes (the French philosopher, mathematician) finally breached the floodgates of the old order by splitting mind from body and proclaiming a dualistic worldview in his well known statement I think, therefore I am (*cogito ergo sum*). One result of the Enlightenment was science, including the scientific capacity for rendering intelligible certain aspects of the material world and for making mankind (in Descarte's own words) Master and possessor of Nature .

This view is on a collision course with how Islam teaches the Muslim to view the world. There is only one master and possessor of nature and that is the One Who created it, Allāh. This is unequivocally expressed in the very first line of the Qur'ān Praise be to Allāh, the Lord of all the worlds (1:1) and the last verse in the Qur'ān Say: I seek refuge with the Lord of mankind, the King of mankind, the God of mankind' (114:1–3) and repeatedly in between. After Descartes, Isaac Newton's world view led to the well known mechanistic conception of the universe and totally away from the holistic and organic interpretation of things. The result was after the 17th century science and religion became totally divorced (Nasr, 1990).

People would find it impossible to live in today's world without money, but one increasingly comes across interesting appraisals of it like the following for example: ••• in spite of all its fervid activity, money remains a naked symbol with no intrinsic value of its own and no direct linkage to anything specific (Kurtzman, 1993). Money has come to be recognized as mere tokens and:

> there is something quite magical about the way money is created. No other commodity works quite the same way. The money supply grows through use; it expands through debt. The more we lend, the more we have. The more debt there is, the more there is.
>
> (Kurtzman, 1993)

These tokens of value that we create from nothing and use everyday grow exponentially ad infinitum. But we know that the natural world, which is subject to drastic resource depletion, has limits and is finite. This equation is lopsided and the question is for how long can we continue to create this infinite amount of token finance to exploit the real and tangible resources of a finite world. Looked at from this perspective, money, as the modern world has contrived it, assumes the characteristics of a virus that eats into the fabric of the planet. The consequences of this become visible as global environmental degradation.

This magical system underwent a metamorphosis in 1971 when President Nixon of the US unilaterally abandoned

the gold standard. This is not the place to go into the background of this event, suffice it to say that, by abandoning the gold standard ••• he also moved the world into a new standard: the interest standard . (Kurtzman, 1993). It is generally known that Islam prohibits usury or the taking of interest and the term used in the Qur'ān for this is riba. (For an appraisal on interest see Diwaney, 1997) This term has wide connotations and simply put, it means one cannot have something out of nothing. Thus, riba is also seen as prohibiting the free creation of credit. The Qur'ān denounces these practices vehemently and we can see why from the foregoing discussion: those who practise riba will not rise from the grave except as someone driven mad by shaytan's (satan's) touch (2:274); also, you who have imān (faith)! have taqwā (awe) of Allah and forgo any remaining riba if you are muminūn (believers). If you do not, know that it means war from Allāh and his Messenger (2:277, 278). No other proclamation in the Qur'ān matches this degree of trenchancy.

The Muslim world today is comprised of nation states (not an Islamic concept) that are wholly or mostly Muslim and Muslim minorities, from the very large to the very small, living in non-Muslim countries. Muslim countries may be divided into two categories. The first, into those that describe themselves as Islamic states but who will freely admit that the way they run their affairs is a far cry from the example laid down by the Prophet, the Right Guided Caliphs and the paradigm of the Qur'ān. The second group consists of secular Muslim states where Islam plays a ritualistic role in varying degrees of intensity. However, both these groups, as willing or unwilling co-optees to the new world order, resort to the methods and institutions that are part of it, in order to trade for instance. One such institution is the banking system, and every Muslim state, Islamic or secular has banks with or without the approval of the scholar jurists who did much to build the Shar¯'ah over the centuries into a potent force for just government.

It should be obvious from this that it becomes almost impossible for Muslims whether individuals or nation states, to give expression to a normative Islam under the present globalized system. A system that is in direct conflict with two fundamentals that are part of the Islamic worldview. There now prevails a schizoid tendency in Muslim society whereby it strives to maintain its deep attachment to Islam while it persists in tasting the fruits of the current order.

However, people are increasingly taking a serious look at the current model of endless growth that supplies a contrived demand for consumer goods, which appears to be insatiable and which is, in the end, impacting on the biosphere with drastic consequences. This concern is reflected in the West by the growth of activism and protest organizations. These same trends (differently expressed) appear in the Muslim world. The form this usually takes is the demand for the establishment of the just order under the Shar¯'ah to replace the socialist and capitalist models, which are now seen as failures. It is difficult to see where these demands for change will take Muslims but it is increasingly felt that the current order is untenable in terms of keeping the planet in good repair.

Muslim minorities, particularly those living in the West, have an important role to play. Living in the belly of the beast gives them the advantage of perspective and their understanding of events could lead to an unique contribution to the melting pot of ideas that could lead us out of this impasse. For example, Muslim groups in the West are re-examining alternative currencies and ways of trading that are based on the fiqh of Islam and not on falsehood (Douthwaite, 1996). Corruption has appeared in both land and sea because of what people's own hands have brought about so that they may taste something of what they have done, so that hopefully they will turn back (30:40). In other words learn from your mistakes.

One could say with a reasonable degree of certainty that the environmental problems we see today would not have happened in a society ordered in accord with Islamic principles because its world view defined limits to human behaviour and contained excess (Khalid, 2000). We have seen how this was done in the realm of environmental protection although its stated aim was not precisely that. Rather it came about in the course of establishing public good, one of the basic principles of the Shar¯'ah. Safeguarding against human excess had the effect of protecting the natural world.

The Shar¯'ah evolved holistically and new situations were dealt with through the processes we have discussed above. However, there is nothing to stop this from continuing. However there are important impediments to its proper application today:

1. The Shar¯'ah is no longer supreme even in Islamic states because of the dominance of the global system now in place. The influence of international trade and finance is a case in point.
2. The Hisbah which was once the environmental enforcement agency is now virtually non existent.
3. Increasingly civil administration is separating itself from the body of the people who are coming to be known as the religious authorities, i.e., a clergy, which is not recognized in Islam. This is the case in the Sunni tradition of Islam, which accounts for about 85% of the world's Muslim population. The Shia tradition has an established clergy. The concept of *d¯n* is wearing thin and as a consequence the holistic approach suffers.
4. Following the Western model, Muslim states increasingly function in watertight compartments. As a mirror of what is happening in the West, Muslim economists and environmentalists are two separate species with opposing perspectives.

5. The nation state model, which all Muslim countries have adopted, has economic development as its highest priority. Coping with environmental change is much lower on the scale.

The following is a crystallization of what we consider to be the essentials which will bring into focus the dimensions of change that are needed today from an Islamic perspective. These ideas have been developed by us over the past decade and discussed at various international forums. However, we are at a disadvantage because the principles we are discussing have been plucked out of the Islamic tapestry so assiduously woven over the past 14 centuries. They work best as part of the whole, but how they fit together in today's context and how the whole can be improved, applied and made sense of are matters for open discussion.

The planetary system, the earth and its ecosystems, all work within their own limits and tolerances. Islamic teaching likewise sets limits to human behavior as a control against excess and it could be said that the limits to the human condition are set within four principles. They are the unity principle (Tawh̄d); the creation principle (Fitra); the balance principle (Mizān); and the responsibility principle (Khal̄fa).

The Unity Principle

Tawh̄d is the foundation of Islamic monotheism and its essence is contained in the declaration (Shahadā) which every Muslim makes and is a constant reminder of faith. It is there is no God but God (lāilāha illa-llāh) and is the foundational statement of the Unity of the Creator from which everything else flows. The second half of this declaration is Muhammad is the Messenger of Allah (Muhammadur Rasulullah). He is Allah, Absolute oneness, Allah the Everlasting Sustainer of all (112:1, 2). It is the testimony to the unity of all creation and to the fabric of the natural order of which humankind is an intrinsic part: what is in the heavens and the earth belong to Allah. Allah encompasses everything (4:125). This is the bedrock of the holistic approach in Islam as this affirms the interconnectedness of the natural order.

The Creation Principle

The Fitra principle describes the primordial nature of creation: Allah's natural pattern on which He made mankind (30:29). Mankind was created within the natural pattern of nature and being of it, its role is defined by this patterning itself. For a discussion on Fitra, see Yasien Mohammed (1996). Fitra is the pure state, a state of intrinsic goodness and points to the possibility that everything in creation has a potential for goodness and the conscious expression of this rests with humankind.

The Balance Principle

In one of its more popular passages, the Qur'ān describes creation thus (55:1–5):

> The All-Merciful taught the Qur'ān, He created man and taught him clear expression. The sun and moon both run with precision. The stars and the trees all bow down in prostration. He erected heaven and established the balance

Allāh has singled out humankind and taught it clear expression – the capacity to reason. All creation has an order and a purpose and is in a state of dynamic balance. If the sun, the moon, the stars did not bow themselves, i.e., serve the purpose of their design, it would be impossible for life to function on earth. This is another way of saying that the natural order works because it is in submission to the Creator. It is Muslim in the original, primordial sense.

The Responsibility Principle

This principle establishes the tripartite relationship between the Creator, humankind and creation. God created everything for humankind and appointed it the vice-regent (Khalif) on this earth: it is He Who appointed you Khalifs on this earth (6:167). This role was one of trusteeship (amānāh) which imposed a moral responsibility, We offered the Trust to the heavens, the earth and the mountains but they refused to take it on and shrank from it. But man took it on. (33:72). This assumption of responsibility made humankind accountable for their actions, Will the reward for doing good be anything but good? (55:59).

We can deduce in outline from these four principles that creation that is both complex and finite is yet exact. It emerged from one source and was designed to function as a whole. Humankind, like the rest of the natural world, was, as part of the natural patterning of creation, in a state of goodness with potential for good actions. It is inextricably part of this pattern, but is the only element of it with choice, that can choose to act against the divine Will using the very gift of reasoning bestowed upon it by the Creator. Submission to the divine will, the natural law that holds in check the instincts of the predator, is the way to uphold our responsibilities as the Creator's Khalif. Humankind are the guardians of the natural order.

CONCLUSION

The position set out in this essay is that of Islam and as we have observed earlier, there is a clear issue of conflicting paradigms. The question is how to implement the teachings and practices of one worldview into an institutional framework devised by another that has a diametrically opposite outlook. Although it may be possible to incorporate the principles of Islamic environmental law into the legislative

programs of Muslim countries, the problem will remain one of implementation unless appropriate institutional arrangements are made to replace the old and now virtually defunct ones. It is also interesting that efforts to meet the challenge of environmental change in Muslim countries are made by secular agencies; this is only to be expected, as this is generally not seen as a Muslim problem. The role of the Muslim scholar jurists has been redefined into a religious one as the nature of the Muslim state has changed in its attempt to cope with modernity. The Muslim scholar jurists were unwilling partners to this change and were replaced by a secularized administration, which gradually weakened the scholar jurists' influence as it began to take charge. However, there is an awakening amongst Muslims to the realities of environmental change and therein lies a paradox. There is just an off chance that this may lead Muslims to the discovery that they may be on the wrong side of the tracks.

Note

The translation of the Qur'ān used is that by Bewley and Bewley (1999). In subsequent references to the Qur'ān in this essay, a quotation is followed by the chapter and verse numbers in parentheses. The actual names of the chapters have been left out for convenience.

Transliteration of Arabic vowels

a pronounced as *a* in cattle, ā pronounced as *a* in father, *i* pronounced as *i* as in n, ī pronounced as ee as in sheep, *u* pronounced as oo in foot, ū pronounced as oo in soon.

ISSC (International Social Science Council)

ISSC (Conseil International des Sciences Sociales) was founded in October 1952 on the basis of a resolution adopted by the 6th United Nations Educational, Scienti c and Cultural Organization (UNESCO) General Conference in 1951, with its secretariat located in UNESCO s headquarter in Paris, the ISSC is an international non-pro t scienti c organization. It has as it aims and objectives the interdisciplinary coordination of research and the promotion of the understanding of human society in its environment. As such, and in line with its primarily organizing functions, ISSC concentrates on the promotion and coordination of social sciences on a global scale. The ISSC, at present is comprised of 14 scienti c international associations/organizations (member associations), six national academies and research councils (member organizations) and a number of associate members, most of them social science associations.

ISSC s ultimate goal is to encourage social scientists and social science organizations to engage themselves in scienti c research of global-scale problems with a special focus on social, cultural and economic issues. In line with this mission statement, ISSC describes its main tasks and functions as follows:

1. to encourage and promote research in the social and behavioral sciences for the bene t and well-being of humanity and its environment, including global issues of concern to the world community;

2. to encourage and pursue global, international and inter-organizational collaborative scientific activities in the social sciences at a multi-disciplinary and inter-disciplinary level among the members of the ISSC;
3. to stimulate, develop, coordinate, enhance and promote inter-disciplinary social scientific programs across institutional, national and regional contexts;
4. to collaborate with the United Nations and its agencies, and particularly with other governmental and non-governmental organizations to further these aims;
5. to provide, through suitable channels, information about its activities and the world's social science community to the public and to other interested parties within the public at large.

In pursuit of these aims and goals, ISSC maintains, at present, a limited number of both interdisciplinary and international research programs. These include the Comparative Research Program on Poverty, and the Conflict Early Warning System Research Program. Together with the International Council for Science, ISSC also co-sponsors the International Human Dimensions Program on Global Environmental Change, a program of special importance for the cooperation between natural and social sciences.

J

Jains and the Environment

Kerry Brown[1•2]
[1]*Harvard University, Cambridge, MA, USA*
[2]*Oakland, CA, USA*

The Jain Declaration on Nature:

> *All the Venerable Ones of the past, present and future discourse, counsel, proclaim, propound and prescribe in unison: Do not injure, abuse, oppress, enslave, insult, torment, torture or kill any creature or living being (Acharanga Sutra 1.4.1.1-2).*
> *translated by Singhvi (1990)*

For nearly three millennia, the Jain people have inhabited a universe that is both inter-galactic and microscopic in its proportions, and bustling to bursting with souls, all of whom are to be treated non-violently (while not proposing harm to microscopic one-sensed beings, Jainism does allow that the practical limit of ahimsa (universal non-violence) is life-forms with two or more senses).

Ahimsa is the first principle of Jainism, and it is a tall order, as the Jains well know. What do you eat? Where do you sit?

The Green consciousness now trespassing on global consumer culture presents a critical challenge and opportunity for a faith that, of all the so-called world faiths, is most obviously and self-consciously saddled with being environmental. If these people can't set an example, who can?

Jainism is of course an indigenous religion, indigenous to India, and most of the seven million Jains still live there with concentrations in Maharashtra, Rajasthan, Gujarat, Madhya Pradesh and Karnataka (Jain, 1986) and perhaps 200 000 Jains in East Africa, the United Kingdom (UK), North America and lightly scattered around the Pacific Rim. More precisely, it is indigenous in the sense that, as well as its 2500 year old philosophical and socio-political roots shared with Buddhism that provide the ascetic, atheistic flavor, and the metaphysical credentials of world religion, there is an older root that is distinctly animist. Together they generate in Jainism one of those invaluable irresolvables that keep a religion alive and tussling with itself. While at one level the Jains are or should be, according to their scriptures, working as hard as they can to get out of the material bondage and heading for eternal salvation, this is a religion that has busied itself with mind-boggling catalogues of the universe's geography, mathematics, biology and physics in which time, space, matter, motion, rest, and souls are all wrapped up together. It is a religion that believes in an infinity of souls that have never existed separately from matter, nor have they created it. Each soul has its own beginningless, endless autonomy, is beleaguered by *karma* (spiritual guilt) that exists as physical particles, and, even after eternal release, will maintain shape and size. It is a religion that has its feet dug firmly, and rather comfortably, in a very real earth while advocating some of the most severe physical hardships imaginable to unearth oneself.

So this is the grain of sand rubbing on the religious order (like the middle-eastern religions' problem of good and evil with an omniscient and beneficent God or Buddhism's compassion for an ultimate emptiness), that either produces a pearl of great value or a very sore oyster. The inner tension has probably contributed to Jainism's long-standing durability and dynamism at both the cutting edge of Indian society and in its courts of power. It is hard to be swept away when the ground you stake is wide, when you've got the skinniest monks and the most well padded magnates. At the most obvious level, the rise of vegetarianism and the demise of animal sacrifice in the sub-continent owe much to the Jains. Mahatma Gandhi's non-violent revolution had Jain fingerprints on it and he acknowledged his Jain friend and mentor Rajchandra Mehta, along with Tolstoy and Ruskin, as the three people who had most deeply influenced him. (Gandhi, 1958). But the modern demands on environmental sensibility and practice are more extensive than even the Jain ascetics' whisk-broom, sweeping tiny creatures out of danger of their tread. And while over 7000 Jain monks and nuns are probably causing less harm than any one on the planet, what about the rest of the Jains?

At a practical level, many Jains are almost outfaced by their faith's complex cosmology and demanding ethics. It is not surprising that they rest on personal vegetarianism, the base-camp of Jainism, and up the ante by removing figs, garlic and onions (thought to have a density of microcosmic life on them), resort to only fruits and leaves of plants, or

just go on a fast. Supplementary actions include sponsorship of one of the Jain animal sanctuaries in India, tree planting, public promotion of vegetarianism and protest on matters such as the killing of millions of cattle with mad cow disease in Britain, culling of kangaroos by Australian farmers, and veal production in Europe. And in the meantime the modern lifestyle of a successful and affluent community has developed which begs all sorts of questions. Nowadays Jain businessmen are part of the industrial complex, jetting the world in planes that dispense more pollutants in one flight than their Mercedes manages in a year, but they would probably still hesitate to burden a horse and ride to London (in Jainism, animal transport is considered an infringement of the animal's autonomy and ease).

Taking the letter of the law expressed a 2000 years ago, identifying its spirit, and creating updated guides for living that are commensurate with where we are now, is a work in progress. This work by one of the oldest guards of the environmental movement has some interesting indicators for us all.

HISTORICAL BACKGROUND

Like most latter-day world religions (with the exception of the body of traditions we call Hinduism), Jainism began as a challenge to assumed spiritual values and, by implication, the socio-economic order.

The first Jains were nirgrantha (the unattached ones). Vardhamana (599–527 BCE) who became Lord Mahavira (great hero), divested himself of the princely trappings of his kshatriya caste, right down to stripping off his clothes and pulling out his hair. He was the 24th and last Jain Tirthankara (ford-builder) in the most recent of the endless cycles of Tirthankaras or Jinas (spiritual victors).

Mahavira was an historical contemporary of Gautama Buddha in the Magadha region, near modern Patna, in northern India. Both men were leaders of anti-brahmanical (and rival) sects in the region, teaching a theory and praxis that had universal law rather than god at the helm, applied itself without caste privilege or the need for brahmanical mediation, and herded souls through the material plane of suffering toward something infinitely more desirable and everlasting. These reform movements were part of the late Vedic period (*circa* 1000–500 BCE) in which meditation and ascetism became paths to a oneness beyond the hurly burly of Indian gods and goddesses. They were also rattling the caste system's cage. Buddhism and Jainism are the only two reform sects from this period to have survived and become religions in their own right, albeit with very different histories, the former fading from India to become one of the largest religions in the world, the latter finding a minority niche in India which it has frequented to this day.

From the start, Jainism, even more than Buddhism, or indeed any other religion, has seen each being's spiritual progress as their personal business, but their physical safety in the meantime as a matter of shared concern. Everybody, however small and simple their consciousness, has a right to be here for their own sake, no one else's, and stay as long as they can, without harm from others. It appears that Mahavira or his followers in some way absorbed a strand in the elaborate braiding of Indian traditions that had a closer eye on the physical here and now. It may have come from previous teachers of the nirgranthas: Pashva, the 23rd Jain Tirthankara (*circa* 850 in Varanasi), or Nemi, the 22nd Tirthankara, thought to have flourished in Saurashtra and been contemporary with Krishna (see Renou, 1953, 114; Jacobi, 1884, 276–279). But from wherever this commitment to understanding the nature and unshakeable physicality of the world came, it has stuck.

> First knowledge of the world, then compassion for it (*Dashavaikalika* 4.10).
>
> translated by (Dundas, 1992, 138)

By the third century BCE, Jainism had divided into two sects, following the sojourn of a group of Jains during famine in the region of modern-day Karnataka. When they returned 12 years later, they were naked and their co-religionists were not. The Jains who had gone south, the Digambaras (sky-clad) sect maintained that complete nakedness was a prerequisite of moksha (eternal release) which also meant that you had to be a man since the female nuns did not take up this practice. This matter and some difference in the details of omniscience have at times led to bitter acrimony between the Digambaras and the Svetambaras (cotton or whiteclad). For the social and doctrinal implications of the controversy, see Jaini (1991).

The Svetambaras are much larger in number and include two reform sects. The Sthanakavasis (hall-dwellers) began in the 15th century and, like protestant movements in Europe and India, decried their religious hierarchy's laxity of practice and trappings of worldly power. The icons of the Jinas and the Jain temples that had become such a spectacular and expensive aspect of Jainism were declared inimical to the process of salvation. Building temples was also reviled for the destruction it wreaked on small life forms in the soil. Sthanakavasi monks and nuns wear a cloth over their mouths, similar to a surgical mask, to prevent themselves inadvertently swallowing small airborne beings.

A further Svetambara split in the eighteenth century generated the Terapanthas (path of the thirteen) who advocated ahimsa (non-violence) as total non-interference, to the good or bad, in the lives of other beings, with the exception of giving alms to ascetics. Both reform sects remain small but are well respected and provide a benchmark of good practice that has influenced the wider community. Despite the Terapanthas non-interference, they are today the most socio-politically active Jain sect.

The other noteworthy matter in Jain history is their survival. What with Hinduism's absorptive powers and the waves of Mughal religious intolerance, it is little short of a miracle to still be there with a distinct identity some three millennia later. The reasons for this as identified by Jaini (1979, 1994), boil down to four general principles which in many ways hold true for Jains' socio-political activity today, environmental and otherwise:

1. *Encourage community participation*: Jain leaders quickly developed a spiritual path and texts for a laity who did not want to renounce everything and take up the life of an ascetic. This laity unobtrusively held their ground when the holy people were under fire from Mughal or Brahman militancy.
2. *Build contacts with the establishment*: Jains had considerable success at converting local maharajahs or establishing an influential presence in their courts. They were seldom completely out of fashion or favor. A Jain monk even managed to persuade Akbar, the Mughal emperor (who reigned 1556–1605) to release prisoners and caged birds and to prohibit the killing of animals on certain days ••• Akbar renounced his much loved hunting and restricted the practice of fishing. However, his enthusiasm took a more predictable turn the following year when those orders were extended and disobedience to them was made a capital offence. (Smith, 1917)
3. *Pick your battles*: in times of strong Hindu resurgence that could have swept them away, the Jaina acharyas (spiritual leaders) kept up their philosophical scrapping with the Brahmans but did not do battle with social and cultural mores. They pegged Jainism tightly to a somewhat rarified spiritual practice. This did of course also weaken their role in social change, as for instance in the acceptance of the caste system as the cultural (but not cosmic) order.
4. *Co-opt popular culture for your own message*: Jain acharyas took the hugely popular arts and literature around Rama and Krishna and produced their own revalued Jain versions. Hindu deities were not so much dismissed from the Jain cosmos as demoted.

The Jain philosophy of anekanta (many pointedness) was no doubt a contributing factor in this diplomatic virtuosity and has remained as an ability to look at an issue and find another way of coming at it.

COSMOLOGY AND PHILOSOPHY

For Jains the physical world is not dismissible either as maya (illusion) or the temptations of Satan, nor is it imminently lovable as the creation of a Creator god. It never started, it will never end and it did not require an eternal spirit to think it up. It just is. Emotions such as love and/or fear of nature that many other religions and the environmental movement bring to it are not appropriate. Maitri, friendliness, with its connotations of detached well-wishing; samyaktva, equanimity; abhaya, fearlessness; kshama, forgiveness for harm done; and daya, empathy, are the key words in the recommended relationship with the rest of the living and non-living world. There is in Jainism a strong tone of pragmatism and a wariness of anything that has a whiff of emotion, of losing one's independence in passion over another, animate or inanimate.

Living and Non-living Entities: Jiva and Ajiva

The second century CE Jain scripture, the *Tattvartha Sutra* (Manual of That Which Is', the only scripture accepted by Digambara and Svetambara sects, translated by Tatia, 1994), explores seven categories of truth. The first category is the existence of souls (jiva), the second is the existence of non-sentient entities (ajiva), namely, matter, time, space, the media of movement and of rest. Both categories are equally real and have been mixed together forever with the aid of subtle karmic matter. The Jain word for a living thing – jiva – is the same word as for soul. To save souls, you save life. And this is not the Neo–Platonic world soul but that of a real person. Every living thing has its own insoluble and unique soul, the knower. It is a horizontal rather than vertical ordering, that recognizes the first principle of ecology, the singularity of each being. It reminds us perhaps not to get so tied up in species salvation that we forget that species is a human taxonomy (using procreative compatibility as the primary criterion) to make order out of a world which in fact never repeats itself. Every individual life is a one-off and has value because it matters to the one who has it. It is not a resource. For this reason an environmental program that included selective culling of species would struggle for Jain support.

> Whatever beings there are, whether moving or non-moving you shall not hurt, whether knowingly or unknowingly. All beings desire to live, no one wants to die. Therefore, a nirgrantha refrains from all acts of injury (*Dasavaikalika Sutra*, 4, 11).
>
> translated by (Jaini, 1979, 66)

The *Tattvartha Sutra* offers the most detailed description of the Jain universe, including mathematical calculations and enumeration of the smallest units of time and space and matter, the qualities and cohesion of atoms, the rings of oceans and islands of galactic proportions and quantity that make up the earthly plane, the categories of life forms according to sensory development, the various classes of karmic particles, the plunging and ascending layers of hell and heaven and their denizens, and even descriptions of black gaps in the sky that are described as dense masses of matter which will suck in a passing god and his spaceship should he veer too near. There is to be sure the ultimate goal of spiritual liberation, but liberation is not so very

distant. It is a state of permanent, disembodied omniscient bliss, still within the cosmos and still within a measurable space. Furthermore, for Jains who are not ascetics, such a vaulted ambition is not to do with this lifetime. They will be reborn.

Like the other eastern religions, Jainism sees material reality as a never ending cycle of creation and destruction, so Jains cannot be so easily mobilized by apocalyptic visions of environmental disaster, as can minds marinaded in the judgement day of the middle-eastern religions. They are mobilized by individual suffering.

Non-violence: Ahimsa (The Philosophy)

> There is nothing so small and subtle as the atom nor any element so vast as space. Similarly, there is no quality of soul more subtle than non-violence and no virtue of spirit greater than reverence for life (*Bhagawati Sutra*).
>
> quoted and translated by (Singhvi, 1990, 6)

Ahimsa is the headline and the subtext of Jain philosophy and practice. It is an intention, a state of mind in which one restrains and ultimately eradicates one s passions, namely anger, pride, deceit and greed thereby restraining the violent acts that arise from these passions. Unintentional harm, even if it kills someone, is not violent. This does leave open the possibility of deciding what is harmful. But the scriptural rider to ahimsa is the proscription against laxity.

Although there are beautiful prayers such as the Kshamapana (prayer of forgiveness) from the Jain scriptures that speak of universal friendship and of deep regret for harm to other beings, the sense of Jain ahimsa is more of non-interference than fussing after. We are not here to protect and coddle other beings or mismanage their affairs, but to let them be. In the business of existence, beings are going to get hurt. So action must be taken with this awareness in mind. Non-action may be preferable. In a hyperactive global society, that thought is almost unthinkable. And of course non-action has its own problems when others are taking actions that are harmful. The live and let live approach, which is often the corollary by which Jains explain ahimsa can be laissez-faire.

Independence: Parasparopagraho Jivanam

Parasparopagraho Jivanam

The popular sutra parasparopagraho jivanam (*Tattvartha Sutra* 5.21) is often translated as all life is interdependent, but it does not have the same meaning as in Buddhism, where the idea of an individual self has only a nominal reality. The individual self is very real for the Jains and one is stuck with it for eternity, so interdependence is interdependence. It is not oneness dressed up as twoness. True,

> One who neglects or disregards the existence of earth, air, re, water and vegetation disregards his own existence which is entwined with them.
>
> quoted and translated by (Singhvi, 1990, p 7)

But ultimately we are all alone.

> Man it is you who are your only friend, why do you want a friend other than yourself? (*Acharanga Sutra* 1.1.3.4. A Svetambara scripture).
>
> translated by (Dundas, 1992, 37)

Action and Reaction: Karma

The principle of action and reaction is native to most religions, and to physical science, and the very basis of our environmental troubles, but astonishingly absent from political and economic policy. For Jains, it is fundamental that your actions *will* have results that will affect *you* as well as others. The mechanism of karma is a major preoccupation in the *Tattvartha Sutra*. Following the categories of sentient and non-sentient beings, the next four categories of truth take up the mechanism of karmic particles, their in ux, binding, cessation of in ux, and falling away, respectively. There is communality about the results, although not to the point that we can quietly unload the results of our misdeeds on someone else and slink off unharmed. Independence is at least as important a tenet as interdependence. The instinctively scienti c mind of Jains is also apparent here. Retribution is not a matter of interference from another dimension. Karmic particles of different varieties exist as subtle matter which ow and stick to us according to our thoughts, words and deeds. They are a missing link between what are usually considered two dimensions, spiritual and physical.

Finally, we must note the seventh category of truth, liberation from worldly bondage that the cessation of karmic in ux makes possible. Much of Jain practice is promoted in the scriptures on the basis of personal bene t on the path to spiritual enlightenment (and tolerable reincarnations in the meantime) rather than for ecological or social bene t. But as we shall see, in the socio-political climate of today, a shift in perspective is evident.

Anekantavada: The Doctrine of Many-sidedness

The Jain doctrine of anekanta, literally, not-onesided, states that all knowledge, except the omniscience of a liberated soul, is only partial truth from a particular point of view. Every individual, not just human, has his or her own unique worldview. All are incomplete but valid views of reality with a personal mix of truth and delusion (courtesy of deluding karmas). Anekanta sweeps away anthropocentrism and dogma. To deny the validity of other s views or to see one as total truth leads to the blindness of dogma.

In Jainism, empirical science is one of five types of incomplete – and until there is wisdom – distorted knowledge. Although there is not the space to explore them here, the Varieties of Knowledge, Gateways of Investigation, Philosophical Standpoints and the Sevenfold Predication of Reality (as both permanent and changing) provide the intellectual grist of anekantavada, and are mechanisms for clearing or at least seeing a few blind spots before trying to find solutions (Tatia, 1994, 9–27, 135–140). It produces an instinctive non-exclusivity in the mind that has done much for Jain survival and which Jains bring to any situation, including environmental problems.

Wisdom, Knowledge, Action: Samyag-darsana-jnana-caritra

The doctrine of anekantavada is downstream from the Three Jewels of Jainism in which wisdom comes before knowledge which comes before action and together they take us to enlightenment. Truth or wisdom is not about the number of practical facts that we have under our belt but the values which inform our selection and the use of these facts in our actions. It seems so obvious (and the Jains are not alone in pointing it out) yet more than 2000 years later information technology is tipped to save the world. And knowing for instance that fossil fuels are harmful, has not changed the fact that our homes and businesses are emitting greenhouse gases as if there were no tomorrow. Modern society is living proof of the Jain philosophy that there are many views, much knowledge, but they do not equal wisdom.

PRACTICE

Ahimsa and the Five Vows

Non-violence in Jainism is essentially restraint. Restraint is related to scarcity of resources but the opposite, the seething abundance of the world and the damage that can be done when you start crashing around in a crowded place.

The Jain laity have been given identity and direction by a set of anuvrats, little vows, that are the same principles but with less strict practices than those of the mahavratas, great vows, of the monks and nuns.

> Abstinence from violence, falsehood, stealing, carnality and greed, these are the vows (*Tattvartha Sutra* 7.1).
>
> translated by (Tatia, 1994)

Ahimsa, non-violence, the first of the five Jains vows is described in the scriptures as the fence of the other vows. All are based on restraint. They are a quintessentially passive position, and therefore deeply antithetical, horrifying even, to globalizing Western culture, yet an increasingly necessary component of effective environmental preservation. How far do you go?

Vegetarianism is the start and sometimes the finish of ahimsa for Jains. No flesh or eggs, and there are many other reductions of diet beyond this; all the way to fasting, which tends to occur in the Jain calendar when other people have feasts. Food and sex are the first ports of call, but restraint in movement of oneself and one's goods, in the accumulation of possessions are all prescribed. Stealing is defined as taking anything that is not given, which, in a world where there is no creator god handing out pastoral rights, puts a very tight reign on our use of natural resources.

Ahimsa and the supporting vows challenging the idea that we should express ourselves as widely and noisily as possible. Just because you can do something doesn't mean you should or that it is worth doing. Self-restraint sits next to the Jain injunction for self-reliance.

JAINS AND THE ENVIRONMENT TODAY

There is among many Jains today, especially the youth, the feeling that saving the environment is their call. Contemporary Jain identity is increasingly identified with nature conservation as a social responsibility rather than primarily a path to personal liberation. Our Environment, Our Responsibility' (front page of Ahimsa June–December, 1997).

Despite the unmatched extremes of their ascetics, *per capita*, the Jains would number among the richest religious communities. Their indomitable interest in materiality has generated fabulous arts and crafts, as well as an economically and politically successful community. Their worldly muscle is beyond their numbers. Professionally, they are concentrated in disciplines and arenas which have direct sway on the post-industrial juggernaut. The mechanism that drove Jains into businesses and professions which these days include the motor industry, agricultural commodities, textiles and their associated chemical industries, information and communications technology, pharmaceuticals, diamond cutting, accountancy, politics and publishing, was the ancient prohibition on professions recognized to be harmful to other life such as animal husbandry and its by-products, forestry, hunting, fishing, quarrying, mining, and the military. Even crop farming is a moral minefield for a good Jain. It's not easy to grow things without killing other things. Once upon a time, business was a relatively harmless undertaking. Now the Jains find themselves in an environmental quagmire. Modern business practice and its growth into sustainable environmental practice is where, potentially, they can contribute most.

The articulation of modern Jain identity is exemplified in two publications of the early 1990s, and in the activity they spawned. The publications reveal developments in Jain thought and social organization as well as some of the processes by which environmental activism is taking hold.

The Right Literature

The Jain Declaration on Nature is a small booklet. The Jains were the eighth faith community to produce such a declaration when they joined the World Wide Fund for Nature (WWF) Network on Conservation and Religion in 1990. (The work of that network has since been taken over by the Alliance for Religion and Conservation (ARC)).

The scale of international input from members of all Jain sects including businessmen, religious leaders, scholars and political figures was unmatched by any other faith. This tiny faith community also produced a declaration that had the biggest circulation. The first print run was 5000 and it has been reprinted twice in English and translated and printed in Gujarati and Hindi. It has operated almost as The Jain Declaration, appearing as basic information at non-environmental events such as the exhibition of Jain art at the V&A Museum in London and the 1993 World Parliament of Religions. It provided text and set a tone for other publications.

The presentation of the Declaration and Jain entry into WWF's Network was, for the Jains, an historic event marked by, among other things, the inaugural souvenir edition of the quarterly Ahimsa with articles on conservation from Jains all over the world. Ahimsa has continued to produce news for the international Jain community with a strong environmental emphasis. The existing Jain press in India, including one of its largest media groups, the Times of India, owned by Jains, also picked up the event and recognized its historic importance.

Refocusing

It is by looking at *The Declaration on Nature* and a contemporaneous translation of the almost 2000 year old *Tattvartha Sutra* and its classical commentaries that we see the dynamism of Jainism in response to its environmental grain of sand. Both works were produced under the auspices of the London-based Institute of Jainology with the collaboration of the India-based Bhagwan Mahavir Memorial Samiti. At one level, there is nothing in the lucid ten pages of *The Jain Declaration of Nature* that is not somewhere in the dense 370 pages of *That Which Is: Tattvartha Sutra*. But although nothing has changed, everything has changed. In *Tattvartha Sutra*, the principles exist in a dizzying cosmological order through which the reader is marched for the purpose of understanding how to free oneself from the tenacious grip of diverse karmic particles that block one's spiritual liberation. In *The Jain Declaration on Nature* these principles and practices are stripped down to the core and described not in terms of the individual's spiritual gains but in terms of the good of the whole natural world. The two are not, of course, mutually exclusive, that is the Jain point, but it is a matter of emphasis.

To take an even more specific example, the all important sutra 5.21 of *Tattvartha Sutra*, parasparopagraho jivanam, which was quoted and elaborated upon in the Declaration, and also appears on its dedication page. The literal translation is most closely expressed as Souls impact one another through their will'. In *That Which Is: Tattvartha Sutra*, the translation is Souls render service to one another' (these services are then identified as both beneficial and harmful). The Declaration translates it as All life is bound together by mutual support and interdependence'. It is a subtle shift of language, a slight change of anekanta, but it is a move from accepting the interference of others whether you like it or not, to actually needing them. Again, as anyone who has family knows, these things are not mutually exclusive.

The variants in translation of this maxim provide an example of how environmental issues are realigning and refreshing humanity's various orthodoxies, not just across what had been a growing scientific–religious divide, but between spiritual traditions. To return to our particular example, the shift in emphasis from independence' to interdependence' by Jains and by the modern *zeitgeist* owes at least as much to Buddhism as to the ecological sciences.

Intra-faith and Inter-faith

There is nothing like a shared crisis to bring people together. Like most religions the Jains have managed to fight more vehemently among themselves than with anyone else; the 2300 year old dispute between the Digambaras and the Svetambaras over the requisites for spiritual enlightenment is probably one of the longest running domestic quarrels' in history. *The Jain Declaration of Nature* and the translation of *Tattvartha Sutra* marked an historic collaboration across all Jain sects whose only precedent had been the celebration of the 2500 anniversary of Mahavir's *nirvana*. Jains from all over the world and all sects came to present the Declaration in London and in the process discovered that amongst them they were doing, and could do, more than they realized for conservation. It opened up channels of individual and organizational communication, which continue to function.

For Jains, joining the WWF also offered the possibility of collaborating with other religious communities on environmental programs. As we have seen, tolerance and collaboration with other faiths is Jain, both philosophically and historically. The journal *Ahimsa* has included positive ecological attitudes of other faiths to highlight the shared ground (*Ahimsa*, vol. 7 no. 4, June–Dec. 1997, 8). This touches on one of the time-bombs of our escalating environmental troubles, the scramble for diminishing resources that will breakdown along community lines, which in the first instance is usually religious. Interfaith work becomes part of a preventive program.

The Establishment and Social Change

The Jain Declaration was the entry document into the Network of the largest environmental non-governmental organization in the world whose president, His Royal Highness (HRH) the Duke of Edinburgh, has championed collaboration with religions. The Institute of Jainology (IOJ) was the driving force behind the Jain Declaration. The IOJ's board of trustees, primarily businessmen, called in Jain political figures in India and abroad, the acharyas of the four Jain sects, the only other all-sect Jain organization (based in Bombay and again dominated by businessmen) and international Jain scholars. The main author of the Jain Declaration was India's High Commissioner to Britain through much of the 1990s.

The Jain Declaration was presented to HRH Prince Philip at Buckingham Palace. Prominent Jains from India, Africa, America and the UK came to present it. The event was surrounded by community celebrations and prayers and spun into the first Jain Environment Day organized by Jain youth in London. It was taken very seriously as a commitment to work with WWF. The Declaration was subsequently presented to the Prime Minister of India.

The environmental outreach to Jains and other religions by WWF and more recently by the World Bank's Vice Presidency for Environmentally and Socially Sustainable Development, taps naturally into that hybrid phenomenon of religion as a world institution. The World Bank heard very clearly from the Jains that agricultural practices such as the feeding of vegetarian animals with the pulped offal of their own species and then the animals' slaughter by the millions in Britain when they subsequently developed mad-cows' disease' is not only totally unacceptable but deeply distressing to Jains.

Jain Environmental Action

What does this mean in practical terms?

Vegetarianism

Vegetarianism is, for Jains, the first vow of any true environmentalist. They continue to be tireless proponents of it throughout India. In the UK where 10% of the population are now vegetarian, the Young Indian Vegetarian Association is Jain dominated and they also have an active role in the national Vegetarian Society. In the process of validating and promoting their practice through public campaigning, young Jains are also being educated ecologically; they are learning about the macro-economic choices for agriculture that raise questions not only about what you produce but how and where you produce and distribute it.

From Animal Sanctuaries to Nature Reserve

Jain animal sanctuaries and hospitals for old and sick animals are a feature of India. In a land where human habitats are under threat by overpopulation, it has been hard to think of, let alone, protect the habitats of other beings. So the first Jain nature reserve was in the UK and was one of the earliest endeavors after the presentation of the Declaration. With the advice of the local council's environmental department, it was established at the largest UK Jain center on the outskirts of London with 32 ha of oak trees, some 300 years old, valuable wetland, and many species including the endangered badger. The reserve was opened on the first Jain Environment Day in 1992 organized by the Jain youth and attended by 1000 local Jains. Local schools as well as the Jain community are actively encouraged to visit it. Every summer the youth association works to ensure its vitality. It provides a small example of a shift in Jain understanding of their ahimsa for other beings – habitat matters.

Reforestation

In India and abroad, tree planting is a popular Jain environmental activity both as a sponsorship by the adult community and as something that children do. Schoolchildren at Bahubali Vidyapith in Karnataka have reforested the hillside behind their school.

Holy places are now also part of this activity. The distinctively designed and superbly engineered Jain temples are among the most beautiful and beautifully maintained in India. And they continue to be built on a scale that has not been seen in the West since the days of the great European Cathedrals. They are important centers of community life. With the exception of the Sthankvasi and Terapanths sects, funding a temple is recognized as a karmically meritorious act as well as one which affords status in the community. Palitana in Saurashtra is the site of the largest Jain (Svetambara) temple complex, more a small town, a stunning cluster of white pinnacles which, until not so long ago wandered over the brown hills of Saurashtra with only one tree left. It is said to be where the first Tirthankara of this epoch, Rushabhdeva, gave his first sermon. Reforestation of these hills with native trees was a direct response to joining WWF. For some years, the IOJ has been working with local Jain trusts, the Gujarat government and their foresters, the local community and ARC. Water systems are in place and planting is being done in batches of 1000 trees. The project has included a 9-day environment camp for 200 students and 10 professors who, along with instruction, planted 2000 trees.

Greening of Palitana' is a model and an attempt to direct some devotional energies and resources swirling around temples toward the natural world.

Jain Youth in Rural India

Over several decades, *Veer Seva Dal* (Brave Service League') in the states of Karnataka and Maharashtra has had youth participation numbering in the hundreds of thousands. The activities have been traditionally Jain, including

strong campaigns for vegetarianism among the rural villages and also native tree planting, much needed in a land where basic human needs for fuel are still tied to wood. Over 100 000 trees have been planted. Hillsides and roadsides to Jina shrines have done particularly well.

This pool of committed young villagers is a potential resource that can be tapped into for a number of tasks, including helping to make the transition to solar energy from wood fuel, eliminating the use of pesticides, and other environmentally sustainable village-level projects.

Western Jain Youth Working the Five Vows

Giving up all possessions, most forms of food, curtailing your movements and, when the time comes, fasting to death, is not the sort of stuff that attracts people in droves any more than telling people they have to give up their fossil fuelled, agri-business lifestyle. As the Jains have discovered, there is a fine line between moderating one's extremes and faking it.

The Jain laity have traditionally used their five vows as a basis for evolutions in their lifestyle, not as a great leap into goodness that never happens. The Young Jains group in the UK took up this approach in their dealings with the environment – identifying modern causes of harm to nature that could become part of one's vows of restraint against violence, those tricky negotiations with the self we all face around the use of cars, levels of consumerism, etc. The principle is basic, but you have to build the habit, and start to create a new normality.

Business: The Hardest Nut to Crack

Given that business was the practice that once took Jains away from acts of *ahimsa*, its role in generating environmental harm is not an easy thing for Jains to face and goes straight to the heart of their current life in the world. As noted earlier, Jains have avoided any professions or businesses where there is use, or traditionally recognized destruction, of the bodies of living beings, but knowledge about how we destroy other life is growing daily. The fact that some fertilizers sold to the third world' are bone meal (often banned in the West), has recently come to the attention of Jain business people who are buying agricultural products such as sugar cane and groundnuts for their factories. If it is confirmed that their suppliers are using these fertilizers, then alternative sources or fertilizers will be found. Yet Jains are the diamond merchants of India, they will cut diamonds for jewelry but they will not mine them because of the damage to earth-dwelling life forms caused by mining. Someone else does that. The importance of highlighting interdependence' in Jain thinking becomes clearer. In modern business it is possible to destroy other life without direct contact with their bodies. You just have to destroy their habitat.

The Ahimsa Environment Award was launched under the auspices of the IOJ at the Indian High Commission in London in 1993 and promoted and judged with the assistance of WWF. The Award took the five Jain vows as the basic questions for competitors to answer:

- *Non-violence*: How has your organization/group reduced its production of harmful waste?
- *Truth*: How open is your organization/group about the impact of its practices on the environment?
- *Non-theft*: How much use does your organization/group make of sustainable and non-depleting resources?
- *Restraint*: How much has your organization/group reduced its use of natural resources?
- *Non-possession*: How does your organization/group implement sharing of the Earth's resources?

The winner in the business category, announced at a dinner attended by three hundred UK Jains, was a recycling paper manufacturer and the runner-up was the creator of ecological balanced plant macrocosms for offices. The Award has not continued but, like so much of the work, it opened a door. Especially for the younger generations, business practice is now linked to environmental practice and to the Jain vows. How far the Jains go with that is still to be seen.

The business and political wherewithal of the Jains and their religious teachings that do not need to have environmental principles wrested from an anthropocentric grip, offer this ancient religion an extraordinary opportunity to be a leader in one of the most important challenges of modern life.

> The Jain tradition ••• enthroned the philosophy of ecological harmony and non-violence as its lodestar •••.
>
> (Jain Declaration on Nature)

> Jains should be leading examples of environmentally-friendly citizens.
>
> (Ahimsa Environment Award promotional leaflet)

Judaism and the Environment

Aubrey Rose CBE
Barnet, Hertfordshire, UK

Judaism is the religion of the Jews. It has a continuous history of almost 4000 years and, like Hinduism, is not only one of the oldest of faiths, but one which has been the source of other major religions.

Although particularistic in being linked to one people, it is universal in its concepts and beliefs. Its uniqueness is that it has survived whether its adherents dwelt in their natural home, the land of Israel, or whether scattered over the face of the earth.

Due to the history and the multi-millennial experience of the Jewish people, Judaism has relevant teachings that are global, that relate to the environment, as well as to the process of change. In fact because it emphasizes learning and action rather than dogma and theology, it has not been in con ict with developing scientific ideas, such as evolution.

Thus, it has been possible for a leading modern ecologist, Professor David Bellamy, to state:

> *It is indeed a sobering thought that the early writings of the Jewish people encompass all the basic recommendations of the World Conservation Strategy.*

It is likewise no coincidence that individual Jews have played a notable role in the advance of knowledge and of science through the ages, and especially in the last two centuries when Jews were gradually freed from institutional discrimination and persecution that had affected them in the past.

> *The earth is the Lord s and the fullness thereof The world, and they that dwell therein.*
>
> *(Psalm 24)*

These words encapsulate the Jewish approach to the environment.

The sense of wonder at the world around us pervades the history and the writings of the Jews. Not only in the biblical creation story of the Garden of Eden, through the founding fathers of the tribe, Abraham, Isaac and Jacob (*circa* 1800 before current era (BCE)), on to the development of the nation in the time of Moses and Joshua (*circa* 1200 BCE), but throughout the thousands of years of Jewish history.

This amazement at the manifold expressions of nature went hand in hand with a realization that there was an eternal force moving through all things, whom the Hebrews called God, and other names, but, unlike all other peoples, insisted that divine force or being could not be reproduced in any physical form. Thus was the purest form of monotheism born.

With such a basic belief, and a relationship of thanksgiving to the Eternal, it is not surprising that the people developed many teachings as to the preservation of man s home, planet Earth, and all that it contained.

Nor is it surprising that, once centuries of clerical and legal oppression were thrown off, and the modern age of scienti c discovery began, Jews, unhindered by theological dogma, played a notable role in the advance of science, the ever-widening systematic discovery of the nature of God. There was no con ict.

Thus, what follows will endeavor to describe in more detail Jewish teachings and practice which, in relation to the environment, were most advanced. Those teachings were based on a belief that we are the recipients of God s bounty, and that the moral law, as to the sanctity of life and living things, is the inevitable corollary of such basic faith.

Judaism is based on both faith and reason, on the soaring idealism of the biblical prophets and on the practical application of basic teachings by the rabbis, over millennia, adapting to changing circumstances. The expression *rabbi* bears no comparison to priest. It simply means one acknowledged to have a degree of knowledge and learning and, hopefully, wisdom, that enables him (or now her) to carry out teaching, and judicial and pastoral duties.

Whilst there is belief in a future life, Judaism is very much a this-world faith, seeking, through a sense of balance and moderation, justice and reason, to advance mankind s physical and spiritual condition, and thus to become closer to the eternal spirit, in fact as the Hebrew Tikkun Olam indicates, to repair the world.

It is a remarkable story, which, despite emanating from a tiny people, has been a major influence on world history. Hence its approach to the environment is worthy of consideration.

The future of our planet and all in it depends largely on Man's own actions. If those actions are guided by a moral law balancing needs, then the planet can survive. If, however, there is no guiding law, and material exploitation proceeds apace, regardless of consequences, then environmental change will be so drastic that we may well destroy the globe, the environment, and ourselves. Judaism is one of the world faiths that try to bring the moral law into our treatment of our home, our planet.

A brief word, therefore, about Jewish history is necessary to indicate the background to environmental teachings.

Whilst there are various theories as to the origins of the Hebrews, the general view is that they emanated from a tribe based at the confluence of the rivers Tigris and Euphrates (now in southern Iraq), their leader being Abraham, born in Ur of the Chaldees. His wanderings took him eventually to the land of Canaan, a land promised to him and his descendants.

Among those descendants were his son Isaac and grandson Jacob, the latter producing a progeny later identified as the 12 tribes of Israel. The group prospered agriculturally, especially when Jacob's son Joseph held a position of authority in Egypt, where most of the Hebrews dwelt for over 400 years.

Persecution and slavery led to the exodus from Egypt of what had now become a nation in about 1220 BCE under the inspired leadership of Moses and thence to the conquest of the promised land under Moses' successor Joshua. Subsequent government by Judges was followed by the appointment of monarchs, the most notable being David who established a centralized authority in Jerusalem.

By 930 BCE on the death of David's son Solomon, the kingdom split in two, the northern half, Israel, succumbing to the Assyrians in 721 BCE, whilst the southern part, Judea, flourished until 586 BCE, when most of its population were carried off to Babylon.

Before the century was out, however, Jews began to return to Judea, to reestablish the Temple as their national shrine, and to continue their religious life. Greek influence later pervaded the land, although sovereignty was regained after the revolt of the Maccabees in about 140 BCE, though Roman control was established in 63 BCE.

Efforts to restore national freedom continued for decades, exploding in the Jewish revolt of 66–70 Current Era (CE), brutally suppressed by Rome, though flickering again in 132 CE, another vain uprising against the dominant Roman power. Jewish sovereignty in the land was not restored until 1948 with the establishment of the modern state.

Perhaps almost as remarkable as the story in the land itself is the Jewish Diaspora (dispersion of the Jews). The Babylonian community flourished for over 2500 years until 1960, whilst, at the time of the birth of Christianity, Jews were settled throughout Mediterranean lands. In fact those communities enabled the Christian message – Christianity being then a sect of Judaism – to bear fruit amongst pagan peoples.

There was also a Jewish Diaspora in Arabia, as indicated in the story of the Prophet Mohammed, as well as in India. The main Diaspora developed in western Europe in the first millennium, developing extensively from about 1500 in eastern Europe. Similar communities arose in parts of the British and Dutch empires, where religious tolerance reigned, extending to South America, the Caribbean, Australia and parts of Africa.

However, the bulk of world Jewry in 1850 lived in eastern Europe. Russian persecution and pogroms led to a massive movement of Jews, from 1880 to 1914 westwards, resulting in the present communities of western Europe and, especially, the United States. Also, from about 1880 began the Jewish return to the land of Israel, though Jews had always lived there throughout the centuries. This movement accelerated with the advent of Nazism in the 1930s, as well as the movement from Arab lands after 1948.

This continued existence of a people largely separated from its native land for such periods of time has continually perplexed historians, as it appears to have no parallel. Yet the sources of this survival are clear, and have a distinct bearing on the Jewish approach to ecology. Most of Jewish history for the first 2000 years of the people's existence derives from the Bible, confirmed frequently by archaeological discoveries, as well as some writings by non-Jewish sources.

But the last 2000 years has seen an immense burst of Jewish creativity, particularly rabbinic Judaism. The first five books of the Bible, known as the *Torah*, and the teachings of the Prophets, set out, not only beliefs as to God and morality, but also highly detailed instructions as to treatment of the land, animals, trees, an ecological blueprint as David Bellamy recognized.

For example the destruction of fruit trees was forbidden, even in time of war, according to the book of Deuteronomy. This was enlarged upon by rabbinical teachings, first in the Mishnah, a codifying operation completed in about 200 CE as well as in the Talmud, compiled during the subsequent 300 years in Jerusalem and Babylon, containing over 3 000 000 words in 63 books.

From the simple admonition not to cut down fruit trees the rabbis and teachers developed the doctrine of *bal tashchit* – thou shalt not destroy – enlarged on by subsequent teachers to prevent people committing waste, the basis of modern recycling processes. The great Jewish philosopher and teacher, Maimonides (1135–1204), in turn enlarged on this basic principle as follows:

> It is not only forbidden to destroy fruit-bearing trees but whoever breaks vessels, tears clothes, demolishes a building, stops up a fountain or wastes food, in a destructive way, offends against the law of thou shalt not destroy'. Judaism affirms without reservation that the world is God's creation and that whoever helps to preserve it is doing God's work.

Clearly most, if not all, major religions developed in pre-industrial times, when populations were small, and when the land, its ownership and use, dominated society. It could be argued therefore that these religions are not relevant to our present problems. But that would be shortsighted and superficial. What religions did, and certainly what Judaism did, was to lay down certain essential principles, often based on moral values, which could be adapted as society evolved.

It is worth looking at a few fundamental beliefs and values of Judaism to see how they affect environmental practice. The creation story in Genesis is instructive. Our environment, our world, all creation, was the work of God. This labor took six days. On each day God looked at what he had achieved and saw that it was good . After the creation of man in his own image , God saw that it was very good .

This story, be it accepted literally or metaphorically, reflects Jewish optimism that life is good, but also that the unity of God is reflected in the unity of all creation. Hear, O Israel, the Lord our God, the Lord is one, is the famous statement of Jewish belief.

Albert Einstein, in pursuit of that unity, refers to the manifestations of the profoundest reason and the most radiant beauty. Enough for me, the mystery of eternity of life and the inkling of the marvelous structure of reality. He reflects the glowing words of Isaiah and the Psalmist as to the wonders of creation, when he refers to a rapturous amazement at the harmony of natural law, which reveals an intelligence of such superiority that, compared with it, all the systematic thinking and acting of human beings is an utterly insignificant reflection .

Evolution presents no problem. As a modern commentator, Chief Rabbi Dr Hertz, states, there is nothing inherently un-Jewish in the evolutionary conception of the origin and growth of forms of existence from the simple to the complex, and from the lowest to the highest .

Judaism regards man, made in God's image, as being at the apex of this structure, enjoined not merely to subdue nature, but also, as stewards or trustees, to till it and to preserve it (Genesis).

Out of this creation story two important environmental teachings emerge. First the institution of the Sabbath day, a uniquely Jewish idea. On each seventh day not only must human beings rest, but also the land, and all the animals, perhaps the first animal right in history. This idea of rest for the land is in complete accord with modern agricultural theory. It extends also to every seventh year (Shemittah), and to the 50th or Jubilee year. Thus, in a way, Jews recognized that man had a duty to respect the rights of the land and of animals, all part of creation.

The second teaching relates to biodiversity. Again and again in the creation story reference is made to of its own kind – grass, seeds, fruit, trees, sea and land creatures, birds, each after its kind. This acknowledgement of biodiversity is reflected also in the story of Noah and his ark, into which went many species, with a view to procreation and replenishing the earth.

This respect for the existence of species, their right to exist, is the basis of the Jewish view of conservation. There is also reflected concern for the individuality of the species. The Bible sets out in great detail which species may or may not be eaten, which species may not be yoked together, e.g., the ox and the ass, as the stronger will harm the weaker.

Indeed concern for animals is reflected throughout biblical and rabbinical literature. A righteous man has regard for the life of his animal (Proverbs) led on to the Talmudic injunction that a man should feed his animals before himself. The Biblical book of Exodus enjoins one to take care of stray animals; even animals of one's enemy, and especially of injured animals. There is a like prohibition against killing an animal together with its young, to prevent one witnessing the death of the other. Maimonides again:

> The panic of animals under such circumstances is very great. There is no difference in this case between the pain of humans and the pain of other living beings, since the love and tenderness of the mother for her young is not produced by reasoning but by feeling and this faculty exists not only in humans but in most living things.

The Talmud, with its diverse opinions from 2000 contributors, is agreed, however, that unnecessary pain should never be caused to animals or living creatures (*tsa'ar ba'alei chayim*). Thus, Judaism is opposed to fox or big game hunting, bullfighting, any use of animals for sport which causes pain. Also abhorrent is the trapping of animals for luxury furs, the mowing down of elephants for ivory or merciless hunting of whales.

For self-defense or for food, animals may be killed, and *shechita*, the process of ritual slaughter, is an attempt to lessen pain caused to the animal. In fact the ideal diet was intended to be vegetarian (Genesis 1.29), but meat-eating was permitted after the time of Noah, provided the blood, the life of the animal, was excluded before eating. This contrasted vividly with the practices of surrounding peoples.

These few points illustrate the extraordinary respect Judaism has for life, in Hebrew, *chayim*. There is sanctity to life, which must be respected. Thus, in Talmudic times capital punishment was rarely carried out. In modern Israel, the death penalty was abolished except for Nazi criminals. Only one person has been executed in 50 years, the Holocaust murderer Eichmann. Even the strict injunction to

desist from work or other acts on the Sabbath is overruled in the interests of preserving life (*pikuach nefesh*).

Modern Israel has become an ornithologist's delight. There is a mass annual migration of birds, of many varieties, northwards and southwards. These birds are cherished and sanctuaries are built for them. Five hundred species of birds have been observed. In almost all Mediterranean countries, there is a mass slaughter and shooting of these migrating birds. Not so in Israel, the birds are living beings. Whilst culling may at times be necessary, to kill birds as a sport is not part of Judaism or the Jewish tradition.

Perhaps Judaism's view of the environment is best illustrated by its attitude to trees. The tree is a thing in itself as well as a symbol. It appears in the first chapter of Genesis. By the second chapter it has become an allegory, the tree of life. The tree in Genesis is instructive. In 1901 Jews established as one of the oldest environmental bodies, the Jewish National Fund, primarily to plant trees in the arid Holy Land. Every Jewish household worldwide has, since then, had a little box in which pennies, cents and centimes were deposited to raise money for trees.

Since 1945 over 200 000 000 trees have been planted in Israel, to prevent soil erosion, create shade, preserve the water level, each tree, of its kind, planted according to the nature of the soil and climate, pines near Jerusalem, cypress on coastal plains, and eucalyptus and acacia in saline soil in the southern Negev and Arava.

In what in early Talmudic times was a well-wooded country, restoration in the 20th century has resulted in 40 000 ha of natural forest, 40 recreation areas and parks, 700 picnic and recreation sites, while scientific planting in the desert-like Negev, savannahization, is creating a new and hopeful situation that could be of benefit to all desert areas in the world.

Whilst Judaism celebrates both a secular and religious New Year, it also has a special New Year for Trees (*Tu B'Shevat*). As winter departs and spring approaches, this festival is celebrated worldwide by a burst of tree-planting, especially by children.

The extraction of oil from land and seabed was a major environmental feature of the 20th century, with prominent political and economic consequences. There is a view that, in the 21st century, water will replace oil as a dominant issue. Seas and rivers, lakes and streams, have suffered from chemical pollution, a significant global change. World health authorities estimate that 80% of disease arises from impure, affected water.

As with trees, Judaism has a similar view as to water. Its purity is vital. It is also a symbol. The Bible, and the rabbis, constantly refer to living waters (*mayim chayim*). But in actual terms, the same principles apply. Water should not be wasted but conserved. Hence, innovative procedures were developed such as trickle drip system of watering plants, desalinization, irrigation procedures, transportation of water by a water carrier, use of solar energy for heating and hot water, accumulating and diverting flood water through dams, creating a marine nature reserve on the Red Sea coast, as well as a process for recycling water and funding steps to prevent marine pollution.

It is instructive to cite an example of, how with the best of intentions, mistakes can be made. The Huleh lake wetland in Galilee was drained, as other wetlands have been drained. The result was not what was expected. The wetland had operated as a natural filter and cleansing mechanism for the Sea of Galilee, slowing down water movement, allowing nutrients to be used by the wetland species. The drainage resulted in problems, causing silting and algae blooms, as well as a loss of species.

So the whole process had to be reversed, and now the Huleh wetland is again a source of joy, for species, birds and people. Another vital Jewish teaching is thereby illustrated, the interdependence of all phenomena in creation, which we disturb at our peril. There is a typical Talmudic story, or Midrash, of God taking Adam by the hand in the Garden of Eden and saying, Look around you. See what I have given you. Look after it well, because if you destroy it, there will be no one to put it right. This illustrates another Jewish belief that we have free will to choose between good and bad, and, environmentally, between positive change and negative change, between sensible conservation and ruthless destruction.

It is possible that just as the plague of human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) burst on mankind in the second half of the 20th century, multiple chemical sensitivity syndrome (MCS) may become the 21st century affliction. It is estimated that one in one hundred people, especially in industrialized countries, suffer from this disease. It afflicts those who are sensitive to all the impurities poured into the air; petrochemicals, pesticides, air fresheners, sprays for home and farm, disinfectants, fungicides, toxic substances, and other seemingly benign substances that actually add to the greenhouse effect and stratospheric ozone depletion. For an increasing number of people air pollution represents a potent, ever-present threat to their health, if not to life itself. Many are prisoners in their own homes. Researchers have now also discovered an alarming increase in bronchial illness, especially asthma. What we are doing is simply poisoning the air, and ourselves.

The problem, even in pre-industrial times, was considered in the Bible and by the rabbis of old. Deuteronomy enjoined the efficient clearance of excreta. The Talmud even stated that one should not live in a place that has no privy (or even no vegetable garden or flowers). How surprising to find in the book of Leviticus advocacy of substantial green belts (*migrash*) around certain cities, a principle developed by later rabbis to apply to all cities.

Maimonides' description of polluted air over eight hundred years ago, cannot be bettered:

> The quality of urban air compared to the air in the deserts and forests is like thick and turbulent water compared to pure and light water. And this is because in the cities, with their tall buildings and narrow roads, the pollution that comes from the residents, their waste, cadavers, and offal from their cattle, and the stench of their adulterated food, makes the entire air malodorous, turbulent, reeking and thick, and the winds become accordingly so, although no one is aware of it.

Maimonides might almost have had some modern cities in mind.

He continues with advice as to where to live so as to avoid the polluted air. All these biblical and rabbinical provisions emanate from the view that the people should be holy, for which purpose cleanliness of mind, body and environment, was essential. One rabbi commented, physical cleanliness leads to spiritual purity . Hands had to be washed before eating, on rising from bed, and after going to the privy. To emphasize the significance or the soul of each act or sight, a blessing (*Berachah*) was to be intoned. Hence, Judaism is full of blessings, for every possible occasion, the gift of food, the gift of beauty, the gift of wisdom, and the gift of life.

The rabbis of Mishnah times, 1800 years ago, even set out views on limitation of noise pollution. Incidentally, *à propos* the population explosion, a major factor in environmental change, the rabbis stated the biblical injunction (*mitzvah*), be fruitful and multiply was satisfied if parents had at least two children.

It is not surprising that the Bible and the Talmud were so concerned with environmental matters. Land and livestock were the chief forms of wealth. Jews were the people of the land as much as of the Book. Their main festivals, New Year (*Rosh Hashanah*), Passover (*Pesach*), Pentecost (*Shavuot*) and Tabernacles (*Succot*), although overlaid with religious significance, were all basically harvest festivals which encouraged men and women to appreciate the cycle and produce of the natural year.

Also, what Judaism did was to bring moral teachings into each festival so that, for example, the harvester is enjoined to leave part of the land's produce for the poor, the widowed and the orphan. This is a biblical injunction, one of the many commandments (*mitzvot*) of the faith. The Bible, apart from its historical and religious content, is also, in effect, a textbook of the environment.

It contains the most wonderful and detailed descriptions of landscapes, animals, and flowers. The Psalms, Song of Songs, Isaiah, Ruth, are full of environmental allusions, decked out in the most vivid and beautiful language.

The Bible has been an immense help to those administering the 280 Nature Reserves in Israel, guiding them in the restoration of animals to the land such as the oryx, which had long disappeared. By chance, Israel, and Jerusalem itself, are at the meeting point of three climatic zones. In the northern half of the country, with its Mediterranean climate, as Professor Safriel, formerly Chief Scientist of the Nature Reserves Authority points out, not less than 25 species of wild progenitors of food plants live in natural habitats. They constitute an unprecedented rich genetic source; a bank of genes for resistance for use by farmers the world over.

He points out that seeds are normally stored in gene banks, whereas the wild plants in their natural habitats are continually exposed to the changing environment and their general constitution is constantly molded by the forces of natural selection . An echo perhaps of the words of Genesis each of its own kind .

Yet another echo relates to Professor Safriel's description of the vital thin layer of microscopic, unicellular algae that carpets the desert surface of the Negev, the southern half of the land. Professor Safriel compares this to the surface in Sinai where the desert is overstocked with goats and camels who tear off the delicate algal mesh and the desert's soil crust breaks and disappears. Interestingly, it was the rabbis of Talmudic times who warned against the damage done by allowing sheep and goats to feed without control.

Professor Safriel adds that Israel as a whole, being at a global climatic transition zone, has major world significance in monitoring environmental change, particularly global warming due to the greenhouse effect. Who would have thought that, when medieval cartographers placed Jerusalem at the center of the world, they may have had a point!

One benefit from being so sited is that the Hebrew University Botanical Gardens in Jerusalem, in its 24 ha, is able to grow plants, bushes and trees native to the five world continents, a treasure of botanic diversity.

Thus, love of land and its produce has been a golden thread running through Judaism and Jewish life from the earliest times. In this century, Jews have developed arboreta, herb gardens, experimental botanic centers for plants and trees, worldwide, from Exbury Gardens in Britain to a plant resource station in Hong Kong, from remote farms in Nova Scotia, Canada, to the hillsides of Brittany, France, and of course, Biblical gardens in Israel and elsewhere.

The following illustrates this attachment to nature. In the eighteenth century in Eastern Europe, there arose an exciting, exuberant, religious grouping called *Hasidism*. They believed not only in study and learning, but in joyful prayer and song. Their founder was to be seen invariably in fields and forests. In 1760, one of the foremost figures of that group, Rabbi Shneour Zalman, married. He received a substantial dowry. With his wife's agreement, the whole of that dowry was placed in a fund to help

Jews develop agricultural settlements and to learn the arts and crafts connected with farming and the land. Thus, though urbanized, largely through external pressures, Jews have never lost their attachment to nature and the land, rediscovering in recent years, particularly with the impact of the return to Israel, the basis in nature for much of their Jewish heritage.

The land of Israel is today beset with numerous and serious environmental problems. These are largely the result of the sudden influx of people from many lands in the last half century, but there are dedicated people imbued with the spirit of the past who actively pursue the causes of conservation and balance between the needs of nature and of society. For example, the high aims and clear philosophy of the Nature Reserves Authority reflect well the principles enunciated by both Bible and Talmudic rabbis, adapted to the modern scientific world. Those aims are summarized by the Authority as follows:

> All living organisms and natural phenomena have a right to exist – nature is beauty and a fundamental component of our physical and cultural existence – nature is quality of life – nature is the main resource for scientific progress which improved the wellbeing of humanity – human progress depends upon a positive relationship with nature – we must practice the wisest use of nature's richness without diminishing its reserves – protection of genetic diversity of wild species found in Israel could be critical for the future of human agriculture and animal husbandry – we are obligated to preserve this life-support heritage for future generations.

Neither Bible nor rabbis could have expressed the Jewish view better.

There are many examples of Jewish teachings on the environment. Only the main points can be touched on in this review. Much of value, especially detail, is necessarily omitted. There is an understandable and perennial problem for scientists, who deal in provable facts, experimentation and observation, in recognizing the religious impulses enshrined in many faiths. Yet modern quantum physics may be moving closer to the insights expressed or hinted at in the teachings of world religions.

Certainly Judaism is not opposed to science, as witness the disproportionate number of Jewish scientists, provided the essence of humanity, of individuality, is not thereby abused. Reverence for life and creation is essential, as also is humility.

When Job rails against fate, God says to him,

> Where were you when I laid the earth's foundations? Do you know the laws of heaven? Or impose its authority on earth?
> (Ch. 38)

The Jewish view of the world is God-centered, not man-created. In Abraham Joshua Heschel's words, the world is not a gigantic tool-box for the satisfaction of man's needs . Rather does Judaism say, in humility,

> How manifold are Thy works, O Lord. In wisdom has Thou made them all.
> (Psalm 104)

These words were echoed thousands of years later by Albert Einstein when, pursuing the idea of a unified field force, he continued to be amazed at the mystery of life, the marvelous structure of reality, and the search to comprehend a portion, be it never so tiny, of the reason that manifests itself in nature .

Another ethical value in the Jewish outlook is moderation. Judaism, from Genesis and the Ten Commandments onwards, through rabbinical law (*Halacha*), has always imposed behavioral limits on individuals. Moderation implies a self-limitation on consumption and accumulation of wealth or as Isaiah described it adding house to house, eld to eld .

On the contrary, the rabbis of old taught Who is rich? He who is happy with his portion .

Hence the ruthless pursuit of wealth, development that takes no account of ecological cost, of the assault on nature, on forests, seas, land, atmosphere, witnessed in the 20th century, is contrary to the spirit and teachings of Judaism as developed over millennia as society itself evolved.

As the pace of scienti c discovery increases, and may perhaps develop in ways we cannot as yet foresee, so the challenge to Judaism, and all other religious faiths, will grow. There will be evolution, adaptation, advance, yet the basic principles enunciated so long ago by the Hebrew prophets and developed, century after century, by the rabbis, will continue to be the guiding light of Judaism and of the Jewish people.

K

Kelly, Petra

(1947 1992)

Petra Kelly was a founder of the German Green Party and a forceful leader of environmental and eco-feminist causes. Petra Karin Kelly was born in Guenzburg, Bavaria, in what was then West Germany. In 1960, she moved to the United States with her mother and stepfather, US Army Colonel John E Kelly, her biological father having left the family in 1954.

Living in Columbus, Georgia, young Petra became involved in the civil rights movement. She went on to study at American University (BA 1970), and won a Woodrow Wilson National Fellowship, serving as a teaching assistant for one year. Kelly was active in the student movements against the Vietnam War, nuclear energy, and for civil rights, social justice and women's rights. She worked as a volunteer in the presidential campaign of the late Senator Robert F Kennedy.

In 1970, her 10 year old sister, Grace, died of eye cancer. Petra responded by founding, with her grandmother a cancer research support foundation in her sister's name. In 1971, she received an MA in political science from the University of Amsterdam. She worked as a civil servant within the European Community headquarters in Brussels. In 1973, she formally adopted an orphaned Tibetan foster daughter, Nima. In 1979, she helped found the Green Party, committed to principles of non-violence and environmental protection. When in 1980 she became party leader, she was the first woman in German history to head a political party. She held the post of chairperson and speaker for the Green's executive board until 1982. On March 6, 1983, Kelly was among 27 Green Party members elected to the German parliament, the Bundestag. She served in the Bundestag until the election of December 1990, failing to win the requisite percentage of the votes, 5%, to ensure parliamentary representation.

Kelly was honored with the Swedish Parliament's Right Livelihood Award in 1982, and the Peace Prize of the US group *Women s Strike for Peace* in 1983. She was on the international board of the World Women's Congress in 1990–1991, within the Women's Environment and Development Organization.

In the early 1980s, she became involved with a fellow Green Party MP, retired Major General Gert Bastien, 25 years her senior. They were inseparable and a powerful force, jointly calling for accountability for superpowers' possession of nuclear and other weapons of mass destruction, opposing German economic ties with South Africa, organizing tribunals to examine human rights in Tibet, and China's treatment of dissidents. She and Bastien were arrested in 1983 for blockading US military bases.

In October 19, 1992, Kelly and Gert Bastien were found in their home dead, both of gunshot wounds. The Bonn police concluded that Bastien had killed Kelly and then himself. No suicide note was left, and Bastien appeared to have been interrupted, stopping in mid-word in a mundane letter, his electric typewriter still on. This and the unlocked upstairs door have left some to suspect an unknown assailant was responsible. Regardless of the theory, two things are clear. Kelly did not die by her own hand, and the world lost an inspiring and powerful voice.

Kondratyev Cycles

see Kondratyev, Nikolai Dmitrievich (**Volume 5**)

Kondratyev, Nikolai Dmitrievich

(1892- 1938)

Nikolai Dmitrievich Kondratyev was an outstanding Russian economist of the 20th century. His work is widely recognized internationally, and the term Kondratyev Long Wave is named after him. (In the US, for example, he became a member of the American Academy of Social Sciences, the American Economic Association, The American Statistical Society, and the American Association on Agricultural Economic Problems.)

Nikolai Kondratyev conducted fundamental investigations into the theory of long-wave economic dynamics; he is the author of works on predicting and long-term planning of economic development and on mathematical statistics and agrarian sector development. The idea of economic long-wave cycles was based on Kondratyev's analysis of a large body of statistical data on the dynamics of the average level of commodity prices, capital interest, wages, foreign trade turnover, and the extraction of cast iron and lead, covering a • 140-year period. Kondratyev not only predicted the great world depression of the late 1920s–early 1930s but he also believed in its inevitability.

Orthodox Marxists attacked Kondratyev's concepts and he was persecuted for his beliefs. He died in one of Stalin's prison camps but he was finally rehabilitated posthumously in the Russian restructuring period.

Landscape, Urban Landscape, and the Human Shaping of the Environment

Brenda Lee
Montréal, Quebec, Canada

For ve centuries, landscape has been used to describe domesticated nature (historically, the British sense), the apparently untouched wild (the American sense) and the pictoral representation of both. It is a complex concept within which the natural and cultural, visual and functional, real and reproduced, interpretive and descriptive, bounded and boundless have been very tightly interwoven. As a technical term, landscape is believed to have been rst used to relate natural and cultural elements in landform by Carl Sauer Morphology of Landscape (Sauer, 1925). In the last two decades its capacity to connect has been exploited by an increasingly wide range of historical, cultural and feminist geographers, and by researchers outside the geographic eld.

Sympathetic branches of archeology, cultural anthropology, culture studies, literary criticism, sociology, philosophy and art history, to link cultural perception of place within society and nature, to the forms that comprise the physical world. Next to place, landscape has become the most important medium for exploring culture - nature interactions. Metaphorically, landscape has replaced context to portray the sweep of signi cant features that meets a focused gaze. Landmarks of its modern use might begin with J B Jackson's founding of Landscape Magazine *in 1951, and include Hoskins (1958); Nairn (1965); Lynch (1972); Williams (1973); Meinig (1979); Watkins (1982); and Cosgrove and Daniels (1988).*

In the natural sciences, landscape ecology developed from the recognition that the proper study of ecology must include Humankind's very signi cant interventions. Applied ecology, although de ned much earlier in the German scienti c literature, was given form in Europe and North America in the early 1930s; it wasn't until the early 1980s, however, that the term landscape was widely accepted as a functionally bounded unit of those patchy ecosystems that Humankind's activities produce (e.g., see Tjallingii and de Veer, 1982, and for an overview of the consolidating disciplines, Schreiber, 1990 and Forman, 1990). The International Association for Landscape Ecology was founded in 1982 to unite the increasingly proli c European and North American work in the biological, geological and geographic sciences. This work has selective links to, but is not integrated with, related activities elsewhere in the humanities and social sciences.

LAND INTO LANDSCAPE: THE MEANING OF THE TERM

The meaning of landscape has therefore never been more complex. Its ambiguity was marked by Meinig (1979) through an identification of 10 of the scenes that it was possible for the scanning eye to behold: nature (the skin of mother earth); habitat (man's domesticated home on earth); artifact (evidence of man's intention); system (of interconnected elements, hydrological to highway); problem (condition of deterioration demanding remedial action); wealth (via a financial appraisal of its worth, existing and value-added); ideology (symbol of the values, the governing ideas, the underlying philosophies of a culture); history (the complex cumulative record of the work of nature and

man in this particular place); place (the unique constellation of characteristics and experiences of each locale); and aesthetic (function subordinated to the painterly laws of intention, form, light and balance).

Two versions of its original and essential meaning exist. The first reaches back beyond the first English usage of the Dutch painters' technical term *landschap* (*landskip* recorded in 1598; the correct *land-scape* in 1603) to the Old English *landscipe*, interpreted as the district or region inhabited and worked by a particular society of people. J B Jackson anchors the old English term in the original neolithic relation of land and its first farming populations. The Northern European Germanic word *land* referred to a clearing and *scape* to a collection of like objects. Similarly, in the southern regions, the Latin *pagus* or *pact*, established the essential socio-political nature of the derivative in modern Romance languages. Landscape was the worked territory of farming peoples. Perceptual definitions are, importantly, derivative.

The second account places more significance on the break in usage (no record exists of the term in middle English) and the cultural development of self that accompanied the exploration of nature as a significant subject of art. Since antiquity, nature had played important decorative, iconographic and supportive roles for the mind, keyed to various symbolic associations; and to medieval and early Renaissance minds, nature was a key medium of Christian symbolism and allegory. It was painters from Switzerland (Konrad Witz – 1400–1447 AD – being the first fully to embed his figures within a topographically identifiable countryside), the Low Countries (Joachim Patinir, Hubert and Jan Van Eyck, Pieter Brueghel the Elder (1400s–1600s), Italy (Giovanni Bellini, Giorgione – Brunelleschi having earlier worked out scientific perspective – 1460s–1500s) and Germany (Albrecht Durer, Albrecht Altdorfer (1500s) who constructed the bases in spatial form and light for the first landscapes that were painted for the value that they had themselves: the 17th century Dutch explorations of nature-based reality that gave interpretive primacy to the individual experiencing subject. This was a time when the new perspective allowed a more realistic and enigmatic nature to emerge on paper, and when the new Renaissance fascination with things-in-themselves began to enliven nature, human and wild. This new nature had a life of its own, and the tension between emblematic projection and expressive interpretation characterizes all early landscape art. The transition from emblem to expression – i.e., from a landscape mirroring cultural associations to that evocative of the personal experience of nature, has been often explored in theatre (Zimbardo, 1986), poetry (Wasserman, 1968), literature (Abrams, 1958) and landscape design (Hunt, 1992). Landscape here has become, in Malcom Andrews' words, worldscape (1999): the myriad of compositions that can be formed from interacting natural and cultural lives-in-themselves. From political to scientific, each picks out its field of significant objects and relationships.

While it is difficult not to use the term *landscape* for all historical treatments of humanized nature, this second understanding is founded in the belief that the concept's modern English formulation accompanies, and depends upon, the individuation and internalization of the analytic Western self. Landscape is, in this sense, essentially a perceived composition of meaningful objects. It is landscape that most accurately represents Cooper's (1992) definition of environment as a field of significance. Landscape, which encompasses the changing patterns of sky, land use and seasonal weather and vegetation, is thus a momentary individual phenomenon, which, like the connoted word, is generalized to a series of widely accepted denotations. This second understanding is sometimes portrayed as purely visual or pictorial; but the aesthetics of land is argued to be much more active, supporting bodily orientation and the related phenomenological experience of being expressly here; doing expressly this (Berleant, 1997; Cooney, 1999) in some space.

The meaning of landscape to those professions dedicated to its design and management has a particularity of its own.

For practitioners of landscape architecture, landscape is narrative: a historically produced composition of biogeochemical forces and the artifacts of human use, which cannot properly be a site of possible intervention until it is understood (see Spirn, 1998). In practice, since conflicts must be resolved and indeterminancies settled in making a design or management plan, only the most practicable outputs of the natural and social landscape sciences can be drawn upon.

For environmental managers, the historical narrative exists, but is normally superseded by the structural detail, which is so difficult to integrate into landscape design: i.e., the characteristics and interactions of its composite units. These units are typically the bounded areas of interest that form patterns within a landscape. Landscape to an environmental or ecological manager is thus the largest functional unit within which smaller sub-units operate, both horizontally and vertically: i.e., an ecosystem. Its study as an (open) system has, since the early 1950s – and more actively, since the early 1980s – gathered together the disciplines previously isolated in specialized studies of ecosystem components (air/weather, surface/subsurface, rock, soil, plants, animals, etc.) so as to assess comprehensively their reactions to, and effects on, human action (see for example, Williams, 1993). *See also* Landscape Ecology, Volume 2.

CHANGING HUMAN PATTERNS ON THE LAND: THE EARLIEST CULTURES

If we move to the earth's landscape itself, the earliest human effects can be traced to the African Old World

tropical forest, whose primates are thought to have given rise to the hominids that first moved out into the grassland and savanna. Through three major glacial periods (500 000–8000 BC) Paleolithic hunting societies survived in small encampments, of which evidence has been found in the north African coastal countries, the east Mediterranean, Italy, France and the British Isles. With the recession of the Wisconsin glaciation, these societies advanced out into the temperate forests of every continent. Their general patterns of movement and settlement (population at that time of around five million) are interpretable through pollen analysis and the relative locations of settlement remains. Those unearthed are small, temporary shelters, the oldest of which lie within the French Terra Amata beach camp (400 000 BC): a grouping of oval huts, sized to hold about 15 people, formed of branches or small trees supported by exterior rings of stones. Palaeolithic sites in general show evidence of hearths (fire is thought to predate the period), wooden spears, hand axes and the separation of living and ritual quarters. It is the paintings in the ritual caves of France and northern Spain that appear to mediate the powerful spiritual relationship between the earliest human societies and their world, where nature appears as a force rather than a place itself.

The agricultural revolution producing the Neolithic landscape (8000–4000 BC) introduced the dynamic force of the human reorientation of natural purpose. Not only were wild grains cultivated (wheat and barley); but both plants and animals (dogs, goats, sheep and pigs) were domesticated – i.e., they were genetically selected wittingly or unwittingly, and thus induced to develop in ways that depended upon human care and will. Control of nature was here being taken into human hands. Originating in the area of the Mesopotamian river valleys, cultivation and domestication were extended west along the shorelines of Mediterranean and Atlantic Europe, changing forest coverage patterns through clearing, exhausting soils and simplifying ecosystems through substitution of the myriad forest and grassland species. Irrigation, which may have started in Egypt about 3050 BC, or perhaps earlier in Iraq, allowed intensification of both agriculture and settlement (development of the hydraulic civilizations of the Tigris, Euphrates and Indus valleys) and brought further changes in the form of salinization, a primary contributing factor in the Sumerian abandonment of land and settlements that peaked about 1700 BC.

In terms of built form, the oldest known Neolithic settlement is Jericho (7500 BC); the largest and most complex, Turkey's Catalhoyuk (6000 BC), which was fed by the new urban function of trade. These are both highly compacted sites, of mud-filled timber frame construction, which turn their backs on the landscape, opening inward and upward. The most haunting remnants however are the Neolithic ritual structures – sacred monuments, temples and tombs – the best known of which is Stonehenge (c. 2000 BC). Built and rebuilt over a millennium, its purpose may have been to understand and celebrate the astronomical geometry of the sky (but this remains under active debate).

Another expression of landscape was perfected in the Egyptian civilization (4000–100 BC) taking its cue from the forms and rhythms of the Nile: 800 km of fertile plain bisected by the river and bounded by desertified grassland. Memorial structures paralleled the river course, the pyramids in Upper Egypt and the temples, incised into the Lower Egypt mountains themselves, to the north. Settlements, although similarly orthogonally disposed, were clearly subsidiary to the monumental landscape, constructed to memorialize what became after the unification of Upper and Lower Egypt (about 3000 BC) the absolute ruler: in the Old Kingdom he was the son of Re, the Sun God; in the Middle Kingdom, he became God himself (Re and the transcendent Amon).

ANTIQUITY

When we turn to Greek culture (a primary root of Western culture), we find the relation between attitudes to nature and patterns of settlement and exploitation to be less clear. Aristotelian *ontology*, or the study of the nature of existence, places Man and his endeavours firmly within the natural realm. On the one hand, Nature was, in general, the theatre of the Gods; and the notion of a pastoral retreat, although immortalized in the Roman poet Virgil's *Eclogues* and *Georgics*, actually originated with the Greek school founded in Alexandria by Theocritus (c. 300–260 BC). On the other hand, the various understandings of civilized human advancement were each tied in some way to the control of natural forces. Greek cities had no treatment of waste; and its agriculture – goats and sheep, vineyards, olive groves and cereal crops – was notoriously hard on the soil cover, particularly on the more ecologically fragile mountain slopes. Coates (1998) remarks on Plato's (unheeded) account of the environmental effects of clearing and overgrazing in his dialogue *Critias*, likening the bared Attic mountainsides to the emaciated form of a once flourishing man.

Coates also points out that, in any case, perception of the natural world for the Greeks was not as a place or locale but a constellation of forces, albeit with human personalities. It was these forces and their biogeological effects that supplied some of the most important design determinants for Greek buildings. City design began as an intuitive response to distinct land formations, the practical art of city building not formally constituted until the Roman technical writings of Pliny, Frontinus, Varus and Vitruvius. In contrast to the static sculptural forms of Egypt, early Greek city building was organic, asymmetrical and

sensitive to the perceptual rhythms of sequential colonnaded space.

The late or Hellenistic Greek city-states formed a foundation for Roman reconstruction in the second century BC. In contrast to the Greeks, the Romans were engineers and administrators, intent on extending Roman law over the colonizable world. This was accomplished through construction of the renowned roads, bridges, aqueducts and lines of fortification, the orthogonal division of land into farming units and the founding of settlements also along orthogonal grids tied most often to shoreline geometry. By the third century AD, Rome had stretched its imperial infrastructure completely around the Mediterranean Sea, north to Scotland, and east to Trabzon on the southeast coast of the Black Sea, founding, apart from most of the important Italian cities – Paris, Nimes, Trier, Lyons, London, Vienna and Cologne.

Roman law made manifest the divine will. The monumental impulse was, as a result, foundational to Imperial construction, which extended the reach of its built form through development of the arch. From the enormous cadenced aqueducts to the massive amphitheatres, stadiums and baths, Roman city design compressed its components into axial routes, moving large quantities of earth to do so. As Coates (1998) again notes, it was a resource-intensive civilization: the Roman baths alone must have consumed enormous tracts of forest. At its most extensive, the Empire reduced the Mediterranean temperate forest to the upper slopes of much of the Middle East and North Africa, stripping the soil of its fertility and flood control capacity as well. Agricultural land was further reclaimed through large-scale drainage of marshlands in central Italy and the Tiber estuary. With an AD 250 population of 1.2 million, Rome itself was a significant source of human and animal waste. The environmental contribution to the Empire's disintegration, although not traditionally recognized, was argued as early as 1864 by George Perkins Marsh to be significant (Marsh, 1970). *See also* **Marsh, George Perkins**, Volume 3.

Although Imperial structures were designed to dominate the land completely, the Jellico and Jellico (1975) point out that design of the smaller places such as the delicately poised Temple of Vesta at Tivoli (205 AD) demonstrated a capacity to balance sensitively the natural and human orders. This capacity was exploited in the Roman gardens, which expanded in importance with the size and luxury of the Roman villa, and the public parks that lined the Tiber.

MEDIEVAL LANDSCAPES, THE ENGLISH EXAMPLE

The disintegration of the Roman Empire into Germanic states in the West and the various components of the Byzantine Empire in the East was accompanied by a decay of its vast urbanized network and of the cities it had fed. Apart from the few that remained as active trading centers, such as London and Milan, and the founding of Rome s Christianized capital, Constantinople (330 AD), most cities disappeared as vital centres. This occurred through losses in population (famine, disease, lowered birth rates) and desertion to the rural areas, where increasingly autocratic estates could provide the protection and livelihood that the Empire under siege could not. In contrast to the classical, the medieval landscape was therefore essentially a working countryside.

Its pre- and post-Roman plant composition and coverage, previously thought to be substantially native, is now argued to have been impacted by intense competition for all land types woodland, peat, forage pasture amongst the peasantry, and between these and the hunting landed gentry. By 1086, 85% of England s native woodland and wood pasture was gone, and many of its large indigenous mammals. Population density then varied by county but, for example, it averaged 13.5 per 100 hectares in the ve east midland counties assessed by the Medieval Settlement Research Group (Lewis *et al.*, 1997). Expansion of cultivation onto the poorer soils subsequently speeded land conversion to the unwooded pasture associated later with England s rolling hills.

The earliest and structurally most important forti cations were the monastic colonies. It was here that the ordered life now tted to the tasks of the new spirituality was maintained until it passed to the urbanizing settlements, complete with clock, account book and structured day (Mumford, 1961).

The later forti ed estates and towns were organized to support the structures and routines of feudal privilege (defense, industry, trade and capital accumulation); at the same time, the unforti ed towns, villages, hamlets, farm clusters and individual farmsteads were organized to meet the needs of the agricultural sector. The commonly imagined medieval town was walled off, having fractured and in lled the Roman grid to create a tight maze of narrow lanes bounded by unbroken building walls, relieved by irregular green spaces, dominated by town and/or guild hall, gothic cathedral, church or chapel, and perhaps a palace or castle. New towns and additions to old ones were normally built along a exible grid, however, and unwalled settlements were often arranged around a broad delineated eld system, communal grazing area or cattle route to upland pasture. Settlement, in general, expanded with the 12th century feudal revolution and died back in the 14th century following the plague (1348 1349) and its recurrences, associated labour shortages, the deterioration of particular soil types that forced a switch from grain cultivation to pasture, and the conversion of whole villages and their eld systems to enclosed pasture (Lewis *et al.*, 1997).

RENAISSANCE LANDSCAPES: ITALIAN AND FRENCH CLASSICISM

A central aspect of modernity is the secularization of many of the elements of the medieval religious framework. The forces that led to this include:

- the spread of a proto-market economy in the 15th century, its move to the outer edges of towns, specialization and increasing trade across Europe, Asia and the Americas;
- the development of the new science, particularly the 16th century challenges to the Scholastics' hold on truth;
- the relocation of divine spirit within the laws and manifest reality of the natural world itself;
- the insight that the inner core of the individual was a realm that was not fixed, but was worthy of being explored;
- the challenge presented by Copernicus and the discovery of the New World putting all previous knowledge in doubt, and fostering a stance of scepticism.

Before the widespread use of the efficient manufacturing technologies that this new philosophy unleashed, the great releases and achievements of the Renaissance remained within its arts. Among the most important of these was the secular garden, the product of a revival of the classical appreciation of nature, classical building form (principally via Alberti) and the increasing attractiveness to the Florentine and Roman aristocracy of the rural retreat. This retreat was enclosed, as was its medieval predecessor, but, since it was set into the Italian hillside, it necessarily offered spectacular views into the countryside beyond.

Of the most accomplished, Alberti's Villa Quaraccchi, Tribolo's Villa Medici and Boboli Gardens, Raphael's Villa Madama, Ligorio's Villa d'Este, Vignola's Villa Lante, the Villa Bernadini, Santi di Tito's Villa Bombicci, and the Villa Gamberaia, the most complicated might be the 1652 Baroque Villa Garzioni, in Collodi, Tuscany. Its seven levels connect a small open-air theatre in the rear, down a sloped parterre, through a series of stair-connected landings, to a central heraldic tapestry of boxed hedge and reflecting pools. What was newly valued here was the relevance of the Roman pastoral ideal: the belief that exposure to the countryside could be a powerful urban antidote, a source of spiritual and aesthetic renewal. And of course from here, the commodification of landscape was just a short step away.

In France, Andre le Notre (1613–1700) (amongst many others) brought the villa garden to its ultimate expression for Louis XIV in Versailles, by wrapping it around the residence and extending its constellations of grand avenues out through the forest to form a great imperial landscape. Views within this extraordinarily complex composition are directed infinitely outward through the use of the long penetrating allee and the recapitulation of sky in its numerous reflecting pools. As Eisenberg (1998) reminds us, this was a landscape in which power was expressed – not vertically as with medieval castles and cathedrals – but horizontally, outward with the expansive aspirations of its Sun King. Its astronomical cost, in materials, water provision for its pools, canals and baroque fountains (a full display consumed more water daily than the 600 000 residents of Paris), potted plants, trees, hedges and the labour for installation and upkeep, not to mention in human lives lost in construction, aggravated publicly that of upkeep of the court. It contributed to the subsequent shift in emphasis to those landscapes which nature could (largely) maintain herself.

THE ENGLISH LANDSCAPE GARDEN

The deepening and extension of the pastoral ideal was accomplished in Britain. The plea for nature as the wellspring of human freedom was first made at the turn of the 18th century by Addison, Shaftesbury, Pope and Switzer, although a garden that would follow nature's irregularity was described as early as 1685 (Sir William Temple's *Garden of Epicurus*). Characterizing the transition from Renaissance formalism to the point at which the English country house was unmoored from its axial attachments and set aloft in a sea of grass, amid archipelagos of wood (Eisenberg, 1998) is Sir John Vanbrugh's Castle Howard (1701–). Himself a set designer, Vanbrugh's achievement was to work out the spatial arrangement of the Palladian redesigned medieval castle and its 16th and 17th century grounds to incorporate the principles and literary references just retrieved from the classical tradition. He alluded as well to his own Gothic past. What he produced was a carefully choreographed blend of ancient, medieval and new: a rolling English meadow partitioned with lake and woodland marked by Gothic references (gates, walls) that recontextualized a series of classically referenced architectural forms (temple, bridge, obelisk, pyramid). In 1770, Thomas Whately wrote that it must be examined, compared, perhaps explained, before the whole design ••• is well understood (Hunt, 1992).

This was in fact Hunt's comment on the landscape at Stowe, the naturalization of which by William Kent (c. 1735) produced one of the most influential (and best maintained) examples of emblematic landscape. Kent's Temple of Ancient Virtue literally engages in dialogue with the Temple of British Worthies across the dip of a lagoon bisecting his Elysian Fields, the grounds overall containing over 30 such referential structures.

Hunt places the transition to a garden that evokes an interior personal, rather than an exterior social, reaction in Kent's Grecian Valley at Rousham (1738). He notes: the subtle varieties of the valley afford a landscape that seems

to answer our moods, that allows a unique and individual response by each visitor to its unobtrusive character (Hunt, 1992). We are here at the genesis of modern landscape. Its arrangement of visual elements and evocative depths are traditionally believed to have been drawn from the paintings of Claude, Gaspard and Salvator Rosa; these may have been more influential in the literary picturesque, however. For spatial structure, argument is made for Renaissance stage design, particularly the court masque scenery of Inigo Jones. The elements of Kent's expressive landscapes were codified by Lancelot (Capability) Brown, whose popularity gave him a tremendous amount of English land to clear, carve, plant and irrigate in his characteristic pastoral mould.

Studies over the past two decades in English art/architectural history and historical geography have pointed to the impacts of the enclosure movement that privatized these grand estates. By transforming the working countryside into genteel recreational grounds, blocking views of distracting functions and aestheticizing the poverty of those remaining on or visible within its frame, those contributing to the picturesque movement not only appropriated land for landscape, but created a universe that eliminated and/or instrumentalized its rightful historic users and use. The shift in ownership also created increasingly concentrated and intensified farms, feeding a growing population and sending increasing numbers of the formerly landed peasantry, into the cities. The pastoral ideal contributes independently of these very real effects, however, and it is possible also to say that an eminently debatable Romantic, expressive view of nature was here taking hold. As Hunt (1992) points out, the picturesque tradition of these designers gave each a frame for admitting a particular amount and form of educated wilderness into the domestic country scene. It is this tradition that has structured landscape design ever since. (See later section on Parks Movement.)

THE EUROPEANIZATION OF NORTH AMERICA

It is now understood that just as the Neolithic agricultural landscape was more domestic than wild, that of the pre-Columbian New World contained complex cultures interacting in equally complex ways with their own native environments. North American ecologists are moving toward their Scandinavian counterparts in the rejection of wild or primitive ecosystems altogether and their substitution by the concept of gradients of human impact (Williams, 1993). Estimates of Amerindian densities in the early 17th century have been raised from sparse to those approaching Western Europe in the American east coast forests. Each Amerindian Nation developed its own means of controlling and exploiting resources: cereal crops and corn were extensively cultivated, fish and game harvested; lines of communication and trade established; territory (and its patterns of use) taken, lost and recovered. Human use is suggested to have produced a landscape mosaic prior to European settlement. The fire used to produce the clearings and shoots that attracted game, and to keep open cultivated land, for example, may have produced much of the midwestern prairie; the fish and game harvested may have reduced species diversity, and certainly limited populations of large game such as elk and buffalo. Relations with nature have been described as a matter of contractual agreement based on pragmatism, fear, and respect born of self-interest (Coates, 1998); but it is clear that they were also tuned to a life within nature for which the West had no appropriate theoretical model.

European conquest replaced indigenous common property conventions with a system of privatization and exploitation geared to commodity production and trade. It famously brought disease, a change in religious orientation, dispossession, and relocation; and environmentally, much more timber clearing, more intensive and destructive patterns of cultivation, much larger permanent settlements and a significant upgrading of resource use. It was depletion that pushed the fur trade – originating along Quebec's Saguenay and St Lawrence routes through the Great Lakes, for example – west to the Rockies. Replacement of fur in the early to mid 19th century with the timber and charcoal industries stripped the US of half its forest cover by the 1920s. Fire further introduced large populations of aspen and jack pine into the then simplified native forests, particularly around the Great Lakes and areas of the Rocky Mountains.

Urbanization began in port towns along the Atlantic and St Lawrence coastlines and remained a port phenomenon until its westward expansion in the 19th century. Until then, people actually moved away from the urban centres to small resource-based communities and farms. Urban society was limited to the few large port/administrative cities in both Canada and the US; if rural, it remained a thin elite layer over discrete areas of countryside. Into the second third of the 19th century, just 8% of Americans and 3% of Canadians lived in towns over 5000. It was not until the colonial economy was superseded by factory production in the last half of the century that significant movement from country to city began, and its specialization at the turn of the century, that the cities began to explode. By 1930 in the US and 1960 in Canada, the urban–rural ratio was 50–50; by 1990 in both countries it was just over 70%.

That life took place within a rural landscape for most North Americans until some time in the mid-20th century did not prevent the shaping of both cultures by views of nature that were strongly idealized. In fact, both nations were deeply split. On the one hand, there was the pastoralism identified with nation in Britain and the US, and the wilderness that turned much of the early Canadian culture inward. The ideal of nature as a cleansing source, as a

retreat from urban ills, is, in all Western cultures, itself deeply ambiguous: it is at once a source of personal/national moral strength and of the elite exclusionism discussed in the previous section (see Buell, 1995 for its American implications).

Practically speaking, its rejuvenative potential was the source of the early Parks Movement (see later section on Parks/Garden Cities Movements); its economic potential was mined unabashedly by the railway industry on both sides of the border in the last quarter of the 19th century, to promote the touristic picturesque. On the other hand, there was another Nature, the Nature that (literally) fed colonial mercantile exploitation and the vigorous industrial capitalism that was established when mercantile structures finally gave way. Here, the dignity of humankind lay in its capacity for control; and John Locke's interpretation of Nature provided the (God) given resources with which to begin.

19TH CENTURY INDUSTRIALIZATION

Industrialization transformed agriculturally based economies and landscapes to economies and landscapes devoted predominantly to resource extraction, refining and manufacture: a development with massive global consequences, both rural and urban. In Britain (the first nation to undergo industrialization), as across Europe, the textile industry, coal mining, and pig iron production, were intensified through introduction of the mechanized loom, the replacement of water with steam power and large-scale iron foundries, thereby tripling growth in industrial towns in the first half of the 19th century.

Factories, coexisting with home manufacture, took over in the last half of the century as the available technology upgraded expectations of what kinds of output could be forthcoming in an increasingly dynamic capitalism. Factories were redesigned to transmit power and reduce the ever-present hazard of fire; they were iron-framed, initially to support the heavy machinery used to spin flax; and made vastly larger and more complex as the scale of operations increased and processes became more diverse and dangerous. Concrete was introduced toward the second half of the century, first in ports and then, as it was cheaper than iron-frame, into construction of the factory buildings themselves. Factory complexes walled in vast courtyards around their central power source(s) creating environments of noise, heat, dust, smoke, refuse and noxious by-products.

Power production depended on, and tended to concentrate around, the coal mines (themselves centres of human and environmental devastation). All this was integrated and increasingly concentrated, first by the systems of engineered canals and then by the new networks of railroads. While there clearly existed many industrial landscapes, those prior to the 1830s stimulated more fascination and awe than disgust; while those during and after the 1830s could, for the vast majority of residents, be characterized by Mumford's phrase, factory, railroad and slum . The pattern of New World industrialization tended to be led by resource extraction, but the industrial cities on all continents were increasingly tooled to produce and distribute the products intended to increase quality of life: the urban environment of production, now severed from that of consumption, was thus unserviced, unrelieved, bleak, filthy and crowded beyond description.

THE PARKS/GARDEN CITIES MOVEMENTS

The appalling condition of 19th century western industrial cities fed the view that urban life, if productive of a nation's finest culture, was in principle bad for the soul and destructive to one's health. Reform was pushed from the bottom up, by women's societies, church groups, physicians, architects, landscape architects, engineers and town planners, particularly in Germany, Britain and the US. Following the 1893 Chicago World's Fair, impetus from North American sources committed to design and civic improvement coalesced into a *city beautiful movement*, producing European inspired designs to ennoble the city's core. These featured the classically designed, monumentally scaled institutions and urban components that industrial cities lacked: grand treed avenues, plazas and parks, parliamentary buildings and city halls, colleges, museums, libraries, etc. What was sought was coherence, visual variety and civic grandeur (Van Noos, 1977). However, the state of the city's basic sanitary, service and transportation infrastructure, fragmentary, often privately (and terribly) run or missing altogether – and of its housing stock – was a concern as early as in the 1860s.

A key component that predated the beautification movement and survived its destruction was the redemptive insertion of Nature into the city as parkland. Its most powerful North American advocate, landscape architect Frederick Law Olmstead, was concerned primarily with integrating the park fully into the large-scale town plans then being initiated and he developed many of the techniques by which this could be done. His designs (along with his partner Calvert Vaux), among them New York's Central Park (his first, in 1858), Brooklyn's Prospect Park, Washington's Capitol grounds, the park systems of Buffalo and Boston, and Montreal's mountain park, drew explicitly on England's pastoral garden design: landform and planting were arranged to isolate the park from the city and to create experiences both of enclosure and of the vastness of nature itself.

Water was wound through meadow and forest; texture was increased through insertion of rocky outcrops and planting variety; experiential variety and surprise were,

overall, inserted into a serpentine formation designed to maximize tranquility. Facilitating this was the separation of vehicular from pedestrian traffic, the roads crossing the park sunk below, thus protected from, the level traversed on foot. Olmstead's strenuous attempts to keep out other reform activities (political as well as recreational) were consonant with his belief that the park must remain an antidote to city life and that political conflict would dissipate within a commonwealth of free and diverse people, contained in an orderly public environment, governed by a benign and sanitary administrative state (Blodgett, 1996).

The obvious problems with this kind of politics in an increasingly structured, and multiethnic, population, combined with increasing pressure for the infrastructure supporting active recreation and team sports, pushed parks design into an interactive, urban phase by the 1920s. Particularly during the post-war boom of the 1950s, parks were created to house the modern recreation facilities: pools, courts, gymnasia, community centres, playing fields and tracks. The new park was a community hub. Further rounds of evaluation were brought about by the city planning exercises of the 1960s and again in the early 1980s, when smaller neighbourhood parks and children's playgrounds were added to increasingly integrated networks, and play equipment was introduced, standardized, or rejected for adventure playgrounds and finally reintroduced.

The redemptive ideal of Nature survives, however, not only in the large open parkland that remains in most Western cities, but – equally importantly – in the now controversial villa in the countryside concept resident in the winding, spacious suburb. What only kings could demand once, was now the prerogative of every commoner who could get hold of the land itself (Mumford, 1961). The standards for urban living laid down in such suburban communities as Olmstead's Riverside (near Chicago, 1869) had been codified particularly by Ebenezer Howard and Clarence Perry into requirements for residential living. Howard's *Garden Cities of Tomorrow* (1902), outlining a cooperative joint-ownership alternative to capitalist land development, placed a network of new urban settlements of fixed population size (32 000) *into* rather than *over* a natural landscape, protecting residential areas from industrial encroachment and both from growth by an encompassing greenspace and the agricultural land beyond. Howard and the members of his 1899 Garden City Association were responsible for England's first new towns, Letchworth (designed by Unwin and Parker, 1902) and Welwyn garden cities (1917); and suburbs (Unwin and Parker's Hampstead Garden, north-west London, 1905–1909). Garden city concepts underlay 13 other British new towns, those in the Union of the Soviet Socialists Republic, Holland, Sweden, Italy, Australia and later variants across both the old and new worlds. They have remained at the core of low-density residential construction (see for example, Hall and Ward, 1998). Clarence Perry's *The Neighbourhood Unit: a Scheme of Arrangement for the Family-Life Community* (1929) systematized conditions he had enjoyed in the Long Island suburb of Forest Hills Gardens. Residential units called neighbourhoods were laid out around community centres and elementary schools, the walk to which would not exceed 15 minutes. In both concepts, all homes were furnished with their own tiny remnant of estate life: the grassed yard.

In this way, the urban fringe that had previously been home both to the rural estates and the dispossessed became accessible to the middle class. The tight walking/horsecar city of the 1850s–1880s, expanded by the radiating corridors of the electric streetcar (to the 1920s) and the local road networks of the 1930s and 1940s finally consumed the vast suburbanizing areas on its periphery, with the construction of the freeway networks of the late 1940s, 1950s and 1960s.

The most memorable and difficult legacy of early 20th century civic design may be that of the wholesale creation of new national capitals: Edwin Lutyen's monumental Edwardian New Delhi (1912–1913) for example; the garden city/City Beautiful-inspired Canberra, work of American architect and associate of Frank Lloyd Wright, Walter Burley Griffith (1913); Brasilia (1960s), the astonishing work of modern art by artist/landscape architect Roberto Burle Marx and a team of architects originally associated with Le Corbusier.

WHERE WE ARE: THE MODERN/ POSTMODERN LANDSCAPE

Modern urban landscapes are clearly identified by post-war efforts to disentangle and systematize land uses (separating home, commerce and industry; street from major artery or freeway); to upgrade use-intensity (achieving a higher capital return, particularly on the new commercially integrated office towers and the interior commercial malls themselves); to highlight the structural monuments to commerce (downtown's ever taller and more distinctive corporate buildings/symbols); and to transform the post-industrial city into a site of consumption and entertainment.

All of these developments have been highly controversial, and attempts have been made since the early 1960s to counteract the separation of city components, the reduction and privatization of public space (streets, squares, parks), the intense commercialization of downtown areas and functions, and the ever-expanding use of adjacent farm and wetland (perhaps started by Jane Jacobs' groundbreaking 1961 work, *The Death and Life of Great American Cities*). There has existed, from this time, a movement that itself is scattered, internally diverse and conflictual to re-instill the best of the pre-industrial city. The new urbanism, in its many manifestations, seeks to reintegrate home and

commerce, restore people and function to public space, compact and diversify the spread-out, single-use areas now comprising modern cities.

To move forward, to the earth's millennial landscape, we might pick up Keekok Lee's distinction between the *natural* and the *artifactual*. The natural is that which directs itself, which contains its own teleology or goal-oriented mechanisms; the artifactual is that which has been willfully produced by Man, the material embodiment of human intentionality (Lee, 1999). Today, the frontiers of human control extend far and run deep. Human-induced change is now, in most of the signi cant realms of the environment affected, of unprecedented size. Many forms of human alteration have either become signi cant fractions of natural change or surpassed it altogether (Meyer, 1996).

It is clear that rates of change, their impact, recoverability and bene ts vary signi cantly across the globe, and that it is no longer possible to label all change to the natural landscape bad. It is, in fact, no longer possible in most areas to distinguish a natural landscape from another kind.

A globalizing economy has brought more of the earth s land surface under a capital maximization regime; at the same time, an increasingly sophisticated microtechnology has allowed human penetration into the smallest of organic processes, taking over genetic control of an increasing array of organisms hoped to provide economic bene t in some way. Some of these organisms have wide-ranging impacts when released into natural environments, willfully or by mistake. The effects of introduced species are controversial, but past experience with known cases has shown that the temporary species enrichment often spells impoverishment in the long term (Meyer, 1996).

> Furthermore, technologies of the rising future, such as molecular nanotechnology, in synergistic combination with biotechnology and microcomputer technology, could intensify this tendency to eliminate natural kinds, both biotic and abiotic as well as their natural processes of evolution or change.
>
> (Lee, 1999)

In sum,

> it can at least be asserted that an overall picture is apparent of unsettlingly rapid, sizable, and escalating change in the global environment. If regions differ in their immediate vulnerability to it, their increasing interdependence in a world economy more tightly knit than ever before may make them unprecedently vulnerable in the long term.
>
> (Meyer, 1996)

We have moved from the inscription of our gods onto the landscape to the inscription of the landscape itself. The number of texts dealing with our understanding and treatment of nature has exploded in the last ve years. They deal with the questions: what can we now call Nature? landscape? and what now, can we experience as our gods? These have become not simply timely, but fundamental questions to a growing number of people.

THE REHABILITATION OF EARTH THROUGH ART

Questions about land, power, form and meaning have been asked and answered most directly in the realm of *land art* (the term *land art* itself is more common in Europe; *Earthworks* and *Earth Art* tend to be used in the US). Thrust into the ow of American art genres in 1968 by a few American gallery renegades, its antecedents explicitly reach back to the earliest human landmarks. The rst of these were clearly spirit-related. In the most extensive and celebrated of the neolithic painted caves, the Lascaux Caves in the Dordogne (25 000 10 000 BC), the placing of animal and human images upon the rock surface seems to have meant to bring into being the forces surrounding the progress of life. The reality of the images literally animates the cave enclosures and structures the experience of its progressively powerful rooms. Neolithic megaliths later made these forces manifest on the land s surface, the tombs and monuments transforming select sites and landscapes into sacred places of ancestral respect. The apogee of these monumental forms however, the later Stonehenge in Wiltshire (2000 BC), seems to have been constructed for the Gods themselves, as were the pre-Roman land scrapings (e.g., Berkshire s White Horse of Uf ngton). These produce images that can only be fully appreciated from above, by a transcendent, celestial eye.

The making of land into monument, paradise, arcadia, temple, tapestry, stage, emblem, canvas and sculpture from Babylon s elaborate hydraulic gardens to the small perfect residential creations of contemporary landscape architects Garrett Eckbo and Michael Hough is land art. The movement that brought the earth s surface back as an explicit medium in the 20th century, however, grew out of the minimalist sculpture of the 1960s, itself created as a series of stark environmental statements. In moves designed to break free of the commodi cation of art, its modernist gallery commercialism, artists sought more democratic, spiritually valid media and viewing sites. Once a small number of sculptors in the US, Germany, Japan and England had discarded the pedestal and the gallery, they began to produce works which formed their own sites. The use of land had been pre gured by Isamu Noguchi s (unbuilt) World War II designs for forms that spoke the unspeakable: *Tortured Earth* (1943) reproduces the bodily ravages of war in large slashed earth mounds; *Sculpture To Be Seen From Mars* (1947) would have mounded the face of a desert into the blank, shocked geometric features of post-atomic Man.

Practitioners were drawn to land art not only by the state of art, but also by the earth, and the practice of landscape

architecture. Michael Heizer sought to found a uniquely American art on the excavation and emplacement of a human geometry on the landforms of southwest desert sites.

I think the earth is the material with the most potential because it is the original source material (Bourdon, 1995).

Walter de Maria began in Germany, but produced his most memorable work in the American southwestern as well. His 1974–1977 Lightning Field near Quemado, New Mexico planted 400 stainless steel poles in a grid aligned for height (averaging just over 6 meters) on the desert floor. The work tends to disappear in the glinting sun of the day and, in the occasional storm, grounds the spectacular play of lightning it is designed to attract. The Bulgarian-born Christo and his wife Jeanne-Claude then outdid the others for spectacle (and socio-economic organization) by (among other similar projects) covering a bay of Australian coastline (*Wrapped Coast, Little Bay, One Million Square Feet*, Sydney 1969), joining two Colorado mountain peaks with 381 m of orange flame and fold (*Valley Curtain*, Grand Hogback, Rifle 1970–1972) and most famously, bringing 5.5 m of gleaming white sail down 40 km of California countryside into the Pacific for two weeks in 1976 (*Running Fence*, Sonoma and Marin Counties). It is Robert Smithson, however, who produced the prose to articulate the movement's soul. Smithson was attracted to the expressive and rehabilitative potential of industrial sites. He is best known for his spiral of limestone and black basalt curving off the shore of Utah's Great Salt Lake (1970).

This site was a rotary that enclosed itself in an immense roundness. From that gyrating space emerged the possibility of the Spiral Jetty (in Beardsley, 1998).

British land art has tended to the more subtle and ephemeral. For Richard Long (*Walking a Line in Peru* 1972, 1975 *Line in the Himalayas of White on Grey Stone*, 1981 *A Line in Scotland*) the walks themselves, the arrangement of stones and artifacts of the actions photographed are his works of art. Hamish Fulton photographs his walks through environments visibly unmoved by human intention. Andy Goldsworthy's *Cracked/Broken Pebbles* (Lancashire 1978) and his gold-leaf wrapped rock (*Yellow Elm Leaves over a Rock, Low Water* Oct. 15 1991 Dumfriesshire, Scotland) set up small beautiful acts of Man in nature. David Nash's *Wooden Waterway* 1978, and *Running Oak Table* 1978 lay odd and distinctly human arrangements of natural materials into a forest clearing. Ian Hamilton Finlay has created a small, densely allegorical neo-classical turf and cut-stone inlay landscape, *Little Sparta* in the Pentland Hills, Scotland. Finlay's return to socially reverential emblems is explicit and changes with his intervention through time.

Land art has also produced the environments more commonly associated with landscape architects. Robert Morris, Herbert Bayer and Andy Goldsworthy have worked with reclaimed industrial and urban waste sites. Michael Heizer used the material and topography of a reclaimed strip mine overlooking the Illinois River to create the massive mounded forms of five indigenous water creatures (*Ef gy Tumuli* 1983–1988, Ottawa Illinois, for the Ottawa Silica Company Foundation). The newest urban land art, however, is the garden, particularly in the hands of designers such as Peter Walker (e.g., *Tanner Fountain* on the Harvard Campus, Cambridge, Mass. 1984, where a sphere of mist is projected over concentric circles of stones placed within a shallow grassy bowl) and Martha Schwartz, whose 1979 *Bagel Garden* turned the front of her Boston terrace house into a tapestry of delicately planted black soil, purple aquarium gravel overlain with shellacked bagels and framing box hedge. Schwartz typically uses unconventional materials and a combination of formal historical and minimal/pop art forms to turn landscape into its own particular art (*see* **Art and the Environment**, Volume 5).

CONCLUSIONS

The very fruitful integration of the natural and social sciences, and the arts, in the study of landscape and cityscape, has paralleled the globalization of human-induced change. This change is an extremely complex, locally distinct phenomenon, sensitive not only to culture and population growth and decline, but also to policy initiatives at every level and the powerful programs of international finance, development and aid.

The compelling attraction of nonhuman nature and of the landscape that reflects its formative forces has, in part, been that of the *essential other*: of the powers and beings beyond our control that surround and contextualize our human life. The modern humanization of the planet itself threatens to recontextualize human life with the products of its own making, that is, to make perfectly narcissistic an existence once shared with its originating forces and beings. What this would do to the conditions of life that have inspired fear, awe, love and creative dialogue since Man has been able to contemplate his own small size is yet to be understood.

Leapfrogging Technology

see Leapfrogging Technology (**Volume 4**)

Leopold, Aldo

(1887- 1948)

The name Aldo Leopold has become something of a mantra among environmentalists. The use of this man's name evokes, from his writings and his personal example, a sensing of the scientific complexity of the biological world, combined with a sensing of the elegant beauty which can be discerned in natural science. It is associated with a code of ethics: a code that offers a moral baseline by which our social system could exist constructively within the limits of biological productivity.

At his birth in 1887 in Burlington, Iowa, there seemed to be no reason to anticipate the intellectual impact that this person would have. At the time of his boarding school at Lawrenceville School in New Jersey, he was noted as a bright and somewhat reclusive lad, who had developed a remarkable ability to see and to interpret nature, with an insight that others could not see. At the time of his graduation from Forestry School at Yale University

(1909), his biographers note evidences that he may have appeared to his contemporaries as quite self-assured: a feature, which might have contributed to some initial management problems during his employment with the United States Forest Service (1909–1924). But during this time, his extraordinary perceptive skills with nature led this young forester to discern two impending catastrophes that others could not see: the destructive effects of runaway deer populations, and the impending debacle of soil erosion. At this early age, he was able to foresee the need for preservation of wilderness, and he originated the establishment of the Gila Wilderness area in the state of Arizona.

When Aldo Leopold published his book on *Game Management* (1932), and became of Professor of Wildlife Ecology at the University of Wisconsin (1933 until his death in 1948), he had earned a reputation as a fine scholar, a writer of impressive power, and an intellectual leader (albeit in a non-classical academic subject). Yet in his lifetime, his perceptiveness and his grasp of ecological issues was not always appreciated. While Aldo Leopold was recognized as the leader of the profession of wildlife management, his efforts to provide scientific leadership in resource management in the State of Wisconsin were voted down. His authorship of some of the most perceptive ecological and philosophical essays focused on the beauty that can be perceived in nature, and led to ethical generalities that were recognized as stunning pieces of writing. Yet four major publishing houses rejected his manuscripts that later led to the book, *A Sand County Almanac*. At the time of his death, in 1948, the power of the mantra of Aldo Leopold was only making its first emergence.

But then, *A Sand County Almanac* was accepted by a publisher just days before he died: note the powerful metaphor of a major leader of ecological and ethical thinking who died while fighting a grass fire on a neighbor's farm. It is probable that his blend of scientific knowledge about natural history, ecology, and management, with the essentials of ethical behavior that can serve as the baseline for sensible ecology, was the powerful pulpit from which he could speak about mankind's relationship to the natural world. I personally doubt that he felt that his writings and teachings would have a very widespread impact. But then the full tenor of his post-mortem voice began to rise in the last half of the 20th century. The readership of *A Sand County Almanac* rose continually during the 50 years after its publication (1949, Oxford University Press, New York), breaking the usual performance of literary/scientific books which ordinarily have a half-life of about six years. Instead of fading, this book has been reprinted more than thirty times, and sold more than two million copies in the last 50 years. It has been translated into nine foreign languages. The demand has been sufficiently great that a second book of his essays was published in 1953 (*Round River*, Oxford University Press, New York). Several other collections of his early writings have appeared (*Aldo Leopold's Wilderness*, edited by D E Brown and N B Carmony, Stackpole Books, Harrisburg PA, 1990; *The River of the Mother of God and other essays by Aldo Leopold*, edited by S L Flader and J B Caldicott, University of Wisconsin Press, Madison, WI, 1991; *For the Health of the Land*, edited by J B Callicott and R E T Freyfogle, Island Press, Washington, DC, 1999; and *The Essential Aldo Leopold*, edited by C Meine and R L Knight, University of Wisconsin Press Madison, WI, 1999). And, most important, a definitive and sensitive biography, *Aldo Leopold, his life and work*, has been written by Curt Meine (University of Wisconsin Press, Madison, WI, 1988).

Today, the mantra of Aldo Leopold has become a byword for environmentalists around the world; this man is considered to be the father of the science of *restoration ecology*. His central role in terms of ethical life-styles has stimulated the formation of a new branch of ethics and morality centered on the health of the Earth. One example of his concise definitions of a land ethic: A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise. People come regularly to visit his farm in Wisconsin as a site of inspiration and intellectual renewal. Aldo Leopold has become a powerful mantra for ethical life-styles.

Being introduced at meetings of environmentalist groups, I have had lovely youngsters shriek, Oh, you must be the son of Aldo Leopold followed by embraces and kisses. At another meeting recently, the chairwoman suggested a standing ovation for the son of Aldo Leopold. It is difficult to define the magnitude of the stimulus that this man has left to the world of environmentalism.

Life Style, Private Choice, and Environmental Governance

Peter Timmerman
University of Toronto, Toronto, Canada

One of the great emerging issues that society faces is the relationship between lifestyle choices and environmental

burdens. The most obvious way of describing this governance problem is the shift from point-source problems, which characterized many jurisdictional responses in the 1970s- 1990s, to current non-point source problems. But it is much more complicated than that, and poses signi cant social, political, and economic concerns for the 21st century.

DEFINING ENVIRONMENTALISM

A central issue in contemporary environmentalism is how to deal with life-styles and private choices. The environmental movement has until now not been able to convince people that many looming environmental problems are rooted in the larger production and consumption patterns of modern society. There is a lot of lip service given to life-style changes, but the underlying patterns are tenacious. To deal with this – many environmentalists believe – will require a transformation of the economic/industrial production system, on the one hand; and on the other, a lifestyle transformation amoung individuals and families. There has obviously been some movement on both these fronts. Industries have been altered; and individuals and households have blue boxes; schools have green curricula; the environment is everywhere. But the environmental agenda is persistently driven by a purity model and not a sustainability model.

The purity model emphasizes clean air, pure water, and the elimination of waste products. It fits in very well with the residual Puritanism of many Anglo Saxon countries, and the whole range of related middle class values. It is naturally associated with personal health, and the general fears about pollution and toxic chemicals. For Ministries of the Environment, this has meant a strong focus on environmental health, on toxin abatement, on end-of-pipe elimination of pollutants, and so on. The environment enters as a carrier or pathway for the delivery of toxic chemicals.

Of course, the other aspect of the environmental agenda is present. People have a broad concern about endangered species and some endangered spaces. There is also broad support for doing something, as long as it is not too onerous (e.g., blue boxes). There are also fears about global climate change and other global issues. But it is clear that after 30 years of the environmental movement that a broad reconsideration of lifestyles by the vast majority of the population in developed countries (let alone developing countries) has not happened.

If it is assumed that consumption of goods and services, especially with the advent of consumerist lifestyles in the developing world, will drastically increase, there are usually two safety valves proposed. The first safety valve is that the greening of industrial production and materials and energy use is rapidly improving, and that will mean that we will be able to continue our consumptive lifestyle without increasing the ecological burden. The second safety valve (related to the first) is that a knowledge and service economy will gradually virtualize a substantial range of current commodity flows.

Neither of these assumptions is completely plausible. While there have been substantial savings made in the elimination of many metals, materials, and energy, the economic growth patterns seem to have simply begun filling the new space available. There is also little evidence that virtualization is going to replace the need for physical resources any time soon. For example, teleworking seems to be a factor in increased car use in suburban belts.

FUNDAMENTAL DRIVERS OF THIS EMERGING ISSUE

Perhaps the fundamental driver of this issue is the model of human well being encapsulated in middle-class ways of life. This is now being promulgated through the media, a model which was embryonic in Southern California and in early suburban New York in the late 1940s, but which has now spread around the world. This lifestyle carries with it a set of intrinsically woven choices about urban and suburban housing, garden structures, transportation biases, and so on. These seem to be only marginally separable, though some separation has been made – for example, smoking and hard liquor consumption patterns have changed drastically over time.

Behind this model is a second driver, namely the powerful assumption of choice as the core element in freedom and freedom of expression. This assumption is historically rooted in a set of religious practices and ideals (concerning free will and sin in Christianity), but has more recently become incorporated within economic theory. In the 19th century, economics was transformed away from a classical model of analyzing supply and demand curves based on resource, labor, and land use, into a neo-classical model which developed the notion of the rational allocation of scarce resources by individuals seeking to maximize their personal utility. This model dovetailed effectively with the rise of consumer society. We now have a cultural model of self-fulfillment encapsulated in the phrase: shopping is freedom. The objects that we buy are now the carriers of self-expression and creativity.

This consumerist ethos is most overtly widespread in children and teenagers, who are acutely conscious of label, product, and status. The school system is currently under assault by corporate marketers and others

attempting to break down the barriers between the cultural space of school and the cultural space of commercialism. At the heart of this struggle is the struggle over who will control the myths, stories, and images of society.

HOW WILL THIS ISSUE FURTHER EVOLVE?

The place of government in this situation is very dif - cult, for a variety of reasons, not the least of which is a long history of misguided government intrusion into trying to reshape human behavior. Nevertheless, the women s movement and other activities prove that governments do have a clear role in fostering and enabling change through legislation, advice, and leadership roles. A simple example of this in the case of consumerism has been government support for alternative automobile eets, recycling, and using pilot activities as examples of best practices.

The big problem, as already mentioned, is the disjunct between personal choice, personal lifestyle and the recognition of those choices and the burden on the environment. I suspect that this is about to alter, in part because the environmental movement is undergoing a signi cant shift in its areas of concern (*see* Editor s Introduction and **Environmental Politics**, Volume 5). It will become ever clearer that the relationship between personal well-being and environmental well-being is much subtler and more powerful than has been credited hitherto. The best example is the extraordinary case of the stratospheric ozone hole, where people suddenly found themselves threatened with the violation of a basic right that they did not even know they had before the right to walk outside on a sunny day.

It will be clearer as the 21st century continues that these kinds of threats threats to the fundamental fabric of life through species loss, climate change, biotechnology, and the rest, will threaten the very de nition of the human. This is already unsettling, but it will become even more unsettling as violations of immune systems, private genetic information, and global deterioration in certain ecosystems accelerate. One can predict that the relationship between these issues and fundamental issues of human well-being will force a recasting of what constitutes the environment and environmental well-being, and that personal sustainability and environmental sustainability will be more tightly drawn together.

This development will allow governments, citizens, non-governmental organizations (NGOs), and industries to renegotiate the boundaries of choice, freedom, and the burdens that current patterns of choice are placing on the environment. This will be very dangerous, but very necessary.

Literature and the Environment

Peter Timmerman
University of Toronto, Toronto, Canada

The relationship between the arts, in general, and environmental change is complex, and certainly not restricted to the presence of images or descriptions of nature as content. Literature poetry, plays, novels, non-fiction is, in part, an alternative environment where the powerful tools of literary form can work within a set of internally generated imaginative rules to explore communicable experience. Literature may be said to have its own ecologies, and has certainly generated worlds of its own.

This article focuses, through the examination of selected pieces of literature, on the Western literary tradition; and for a variety of reasons, including space restrictions, deals with the mainstream tradition, particularly in works of the Romantic period (1750 1850). One of the other reasons is that Romanticism is a pivotal moment in modern literature, as well as culture more broadly; and it is a direct in uence on the rise of modern environmental thought and practice. To elucidate the importance of Romanticism, I draw upon the myth-critical school, associated with the work of the Canadian literary critic, Northrop Frye (1947, 1968), which, whatever its limitations in other areas, provides a very powerful apparatus for entering into some of the more revolutionary aspects of literary practice as it applies to cosmologies and mythologies.

In particular, this article argues that a central role of literature in the context of environmental change is to be an expression and sometimes a fomenter of changes in world views. This is one powerful way in which literature interacts with environmental change: that is, not just recording people s feelings about changes in the natural environment, but challenging and restructuring their mental maps of the world by means of story, character, style, language.

INTRODUCTION

In the summer of 1816, a group of English hippies including Lord Byron and his friend Percy Shelley went to Lake Geneva in Switzerland. Coming after the battle of Waterloo, 1816 was the rst time that anyone from England had been allowed to travel in Continental Europe for a decade, and tourists ocked across the Channel. Lake Geneva was special because it had been the site of a famous romantic novel by the French philosopher Jean-Jacques Rousseau, *Julie: or The New Heloise*, and

the little party of travelers was looking forward to a summer of wandering around the shores, soaking up the atmosphere.

Unfortunately, the summer of 1816 was the year without a summer thanks to the explosion of Mount Tambora in the Southeast Pacific, which cast a pall over the skies of the world, and cooled off or deranged weather patterns everywhere. Lord Byron and his party were forced to stay inside their rented house and watch the rain, day after day. On one such day, they all decided to make up ghost stories. Shelley's wife, Mary, had a dark dream, which she turned into what everyone agreed was the best of the ghost stories, about a scientist who decides to create a human being. Thus, *Frankenstein* (Shelley, 1818) was born.

This is an interesting example of the relationship between the environment and literature, and highlights one way in which much of the creative interplay between the constructed world of human culture, and the natural world within which that culture is created, works. It is almost a parody of the not very creative idea that the environment might be a cause of literature, the way people used to argue that geography causes culture. It is only marginally less creative than the conventional notion that the environment appears in literature as the content of the novel, poem, or play.

A more useful way of thinking about literature and the environment derives from the Romantic movement of the 18th and 19th centuries – though not completely beholden to it – which focused on seeing literature as in part an expression of human exploration of the relationship between the self (consciousness, mind, imagination) and the outside world (nature, environment, materiality); but that the nature of this expression was not just the content, but the quality of style, the voice of the author or narrator, the shape of the stories being told, and so on.

One critical element in this exploration is provided by *metaphor* – the imaginative leap between two different realms or categories as seen by the creative mind. This mind need not be a literary mind – the Gaia Hypothesis (*see* Gaia Hypothesis, Volume 5), that the Earth might be seen as a single, living organism – is a creative metaphor; though many scientists would opt for its milder cousin, the *simile*; that is, the Earth may be treated for the moment as if it were akin to an organism, or a self-organizing system of sorts. Another example is provided by the 19th century chemist, Kekule, who could not solve a problem in the arrangement of chemical bonds, and had a dream about a snake biting its own tale, which gave him the idea of the potential for the circular bonding pattern: another creative metaphor.

METAPHORIC AND RATIONAL LOGIC

The anthropologist Gregory Bateson, just before his death, wrote a pathbreaking comparison between metaphoric and rational logic through comparison of two syllogistic patterns (*Men are Grass*, Bateson, 1987). The first, very familiar, syllogistic pattern is:

Men die.
Socrates is a man.
Socrates will die.

This Aristotelian syllogism is (in part) a deductive machine with a hypothesis (Men die), a fact in the world potentially subsumable under that class (Socrates is a man), and then a new relation when the fact is put into that class (Socrates will die).

A second pattern, which looks like the first, but is in fact a logical fallacy is:

Grass dies. Men die. Men are grass.

This is the fallacy of affirming the consequent, and its fallaciousness (and dangerousness) can be seen in the following further example:

White is pure.
There are white people.
White people are pure.

The grass syllogism, however, is familiar to readers of the book of *Ecclesiastes* in the Bible, as a powerful linking together of two different categories (men, grass) by means of metaphor. This kind of categorization and making of connections can be as systematic and powerful as the rational logic associated with scientific hypothesis generation; but the *two solitudes* (to use C P Snow's term) can be antagonistic to each other. Indeed, it has been one of the complaints of the modern poet that the scientist is draining all the poetic mystery out of the world, by challenging the traditional web of metaphoric connection; while, on the other hand, the scientist complains that writers don't know any science.

What makes the writer's world work is the making of connections that may not be overtly rational, but may make meaningful sense as metaphor. For example, there is no scientific reason why blue should be associated in Western culture with the musical *blues*, but most writers will be able to play on those associations when necessary. Similarly, the idea that a weeping willow is actually weeping is obviously absurd to a botanist or forester; but as a symbol, it may well be a powerful carrier of an emotion in a story.

One thing that separates modern literature from earlier literatures (and non-Western literatures) is that earlier literatures can depend on the expectation that the entire culture within which the literature operates also subscribes to metaphoric logic. It is only in modern Western culture that the idea that nature and human experience have no metaphoric connection to each other has flourished.

Among the reasons why Shakespeare continues to have such an influential role in modern culture is the fact that

he lived at a pivotal moment in the shift away from a universe of mutually resonant meaning (the end of the 16th century), and is sensitive to the shift, very often giving us some characters who still respond to traditional signs and symbols of the environment, and others, more modern, who dismiss them merely as old wives' tales.

As an example of the former, the night before Julius Caesar is stabbed in Shakespeare's play *Julius Caesar* (1597), Cicero and Casca speak. Casca reports on what he is seeing:

> Casca: Are you not moved, when all the sway of earth
> Sways like a thing unfirm? O Cicero!
> ••• never till tonight, never till now,
> Did I go through a tempest dropping fire.
> Either there is civil strife in heaven,
> Or else the world, too saucy with the gods,
> Incenses them to send destruction.
> Cicero: Why, saw you anything more wonderful?
> Casca: A common slave – you know him well by sight –
> Held up his left hand, which did flame and burn
> Like twenty torches joined; and yet his hand
> Not sensible of fire, remained unscorched •••
> Men all in fire walk up and down the streets,
> And yesterday the bird of night did sit
> Even at noonday, upon the market-place
> Hooting and shrieking. When these prodigies
> Do so conjointly meet, let not men say
> These are their reasons, they are natural ;
> For I believe they are portentous things
> Unto the climate that they point upon.
> Cicero: Indeed, it is a strange disposed time;
> But men may construe things after their fashion
> Clean from the purpose of the things themselves.
>
> (I, III, 4–35)

Here Casca represents the world of symbols, portents, signs from the gods, that are warning of impending civil war; while Cicero represents the newly rational Man, sceptical, aware of how signs may be false, mere rumor, hysteria, and connected only by projection from human desire.

NATURE AND MYTH IN PRE-MODERN COSMOLOGY

We can think of cosmologies – proposed descriptions of the universe – and mythologies – stories that inhabit and illuminate the universe – as forms of metaphor writ large. They are large-scale structures of meaning, many of whose elements and characters appear in literary works, while the works themselves influence the overall feel of how it is to live in such a universe. For example, Dante's *Divine Comedy* (1330) is an imaginative journey through the cosmology of medieval Western Europe; but the power of Dante's vision of his journey had incalculable effects on the birth of the sense of what it means to be a modern Western individual in such a universe.

In this section I want to sketch out two rough cosmologies, the first from the beginning of literature, in Sumeria; and the second, the evolving medieval Christian synthesis cosmology that broke down at the beginning of the modern era. These are not the only cosmologies available. They are simply two of the most important, particularly for the ways in which they think about, and structure, in myth and story, the cultural map of Nature.

In most cultures, the cosmology is woven into stories that are told orally, and have been handed down by word of mouth for many centuries. The Western tradition is special (which does not mean specially good), in that much of its tradition was very quickly written down, and the mainline tradition has been a strongly literary one from very early on; though the origins of the stories that make up the tradition are almost certainly long oral traditions that have been lost or rewritten. Western traditions begin the story of the creation of the Earth and sky usually with some kind of a Creator God, and often with a story about how the sky and the Earth came together and mated (the sky being male, and the Earth being female). A number of other cultures start things off completely differently. For some, the universe comes out of its own insides, like a spider spinning a web out of its own guts. For others, everything comes up to the surface of the sea; and that is how things got going. In some cultures, things are even sung into existence.

It should also be stressed that what is being sketched out here is the mainline Western tradition, against which other oral traditions and contrary stories struggled, and often lost. Of particular importance is the continual appearance and disappearance of dangerous story fragments about women and other strange beings whose role in the mythology is troubling and often suppressed or twisted. Scholars have only recently become interested in these marginalized stories, in part because of the light they shed on mythologies that refused to fit into the big story.

The Origins of Earth and Sky

The first myths in the Western tradition of which we can read begin in the Near East, and are associated with the hydraulic civilizations of Sumer (Southern Iraq), Egypt, and later, Babylon, and Assyria. These cultures grew out of the surpluses generated by the ecological richness of alluvial soils in the big river basins of the Nile, Tigris, and Euphrates rivers. Through extensive irrigation and complex management works, these cultures were able to feed large numbers of people, and also build the world's first big cities (the same process was going on in India and China). Essential to the survival of these cities was the organization that kept the irrigation systems going, and the predictability of changes in river flow according to the seasons. Furthermore, as these cities grew richer, they became subject to attack by enemies, which necessitated the

growth of armies. All this complexity led to the creation of writing, accounting, and monumental architecture.

In the earliest Western stories drawn from the Middle East, the Earth is seen as a piece of land (often a hill) surrounded by, or floating on, the waters of Chaos, waters that will drown the world unless they are countered by creative power. However, these waters are also life giving, especially in an area with so little rain: in some myths the great waters are the source of all beings. By analogy with a room or a temple, the Earth is often seen as holding the sky up by four pillars on each corner, representing the four directions, and we still use this image in talking about going to the four corners of the Earth.

The Earth has its natural rhythms associated with seasonal change, the rising and lowering of rivers, seedtimes and harvests. The Sky has an intimate relation to this process, but it seems to be much more abstractly orderly, more designed, less subject to human influence. Unless you are an astronomer, the sky at night presents the following picture: there are fixed stars, that do not seem to move relative to each other, though they move as a whole through the night sky through the year. They have strange patterns, called *constellations*, which look as if they might mean something, especially those associated with seasonal shifts. Every once in a while, certain stars seem to move, called *planets*, which is a Greek word meaning wanderer, because they seem to be wandering among the stars. These appear at different times of the year, which can be predicted, but they move in a puzzling fashion. Also in the night sky in the Northern Hemisphere, there is a swatch of white stars called the *Milky Way*, which many myths see as some sort of gateway to heaven.

Obviously, the moon is the largest body in the night sky, and it has a monthly rhythm which is predictable, and which was very early on associated with the highs and the lows of the tides of the rivers and sea. Because of its similarities with female rhythm (the word *menstruation* derives from a word for month), the moon was constantly associated with the female, and with tidal waters. This is not universally true, but became more and more accepted in Western myth.

Most important of all was the sun, which very quickly became associated with ruling power. Some cultures, such as the Egyptian, toyed for a while with having a Sky Goddess (Nut) separate from the Sun God, but this rapidly disappeared. The sun was all-powerful, and ruled the day. Most of the gods and heroes of the Near East were associated with the Sun God, who was invariably male, and kingly. Crowns had rays of the sun attached to them; kings carried orbs (the sun symbol) and the chariot of the King moved over the world the way the chariot of the sun moved across the sky.

To reinforce this, the earliest agricultural myths explained the creation of the world as the sexual intercourse of the Earth (female) with the Sky God or sun (male), and this would be symbolized by the plow (male sexual organ) entering the furrow of the female (female sex organ), and seeding the soil with semen. Other versions of this would connect the Sky God with the rain, again, male potency being rained down on the waiting female Earth. These myths strongly reinforced the idea that the male was active and creative, while the female was passive. This helped set up a whole pattern of male-oriented myths of power, that reinforced the social organization of the period, which was becoming increasingly dominated by priests, kings, and hierarchical organizations. This was essentially patriarchal, i.e., dominated by a male-structured mythology.

There are indications, though the evidence is extremely controversial, that there was at least a strong counter mythology, especially in other regions of the Near East such as Crete, that focused on the power of women, particularly associated with their dominant role in early agricultural practice and in their role as childbearers. This matriarchal culture is very often characterized (in the surviving male cultural mythology) by a myth of a powerful Queen choosing her temporary male partners, who are perhaps sacrificed when they lose their usefulness as defenders.

In the earlier period there were several different stories, and competing gods. For instance, another important piece of the cosmological structure was the God of Storms, who sometimes competes with the Sky God for supremacy; as do other gods associated with primal forces, like fire. These cosmologies altered significantly with changing social structures, though the main lines began to harden. By about 1000 BCE in the Babylonian epics and stories, a mythical structure was in place which was picked up and modified in part by the Israelites, a wandering tribe of shepherding peoples who seem to have traveled throughout the Near East, settling in Palestine following experiences in Egypt, captured in the oldest parts of the Bible.

It was this adoption of the reigning Near Eastern mythology as a backdrop or set of assumptions in the early books of the Bible that was so important for the rest of the Western tradition.

The Rise of the Hero

One last element of this mythology needs to be put into place, which is the idea of the hero (and occasionally the heroine) who usually represents the human race in its struggle to survive in a strange world. This hero is almost always seen as more than human, a superman, or Hercules, who is related to the Gods in some way. This hero has a series of adventures, which carry him through the world, and help to make sense of it.

This hero structure often mirrors the activities of the Gods in sustaining the world. For instance, one of the great myths of the world is the sun going into the darkness every

night, and being reborn every morning. The darkness is like chaos: a place of confusion and death. The hero, following the track of the sun, goes down into the place of darkness at the end of the world, or the bottom of the world, and there wrestles with various evil forces, and then resurfaces to begin the cycle of the world all over again. The hero travels through various levels of the world, from the highest to the lowest and back again.

Let me summarize all the above in Figure 1. It represents a composite of the Western worldview, about 700 BCE, which would be found with variations all over the Near East and the Mediterranean.

The most important single fact about this myth structure is that the higher up you go the more ordered it becomes. This is because God or the Creator is also the embodiment of order, and the human beings who are closest to him, the kings and the priests who rule human society, also embody order. Notice also that the highest order is more and more removed from most natural processes. This suggests that the higher order is rational, and associated with the powers of the human mind separated from the turbulence of the lower world.

A second important fact for mythological purposes is that the imposition of order from the top down is a central part of any story that fits within this structure. In general, the king, Sky God, God as Creator, is visualized as coming down into the disordered world and imposing order on it according to a rational plan. The resistance to that is seen to be irrational, and associated with the demonic. The farther down one goes, the more ungodly Nature is, the more dangerous, and the more associated with darkness, uncontrolled swirling water, and chaos.

The process of myth creations takes these levels, and the images and symbols associated with these levels, and weaves them into powerful stories. We have already referred to the story of the hero who descends into the realm of darkness and wrestles with the darkness. The darkness is associated symbolically in geographical terms with caves and labyrinths; bodily with the lower bowels (the bowels of the Earth); meteorologically with wild chaotic oceans (as in storms and tempests); and animalistically with huge devouring serpents, gigantic whales, beasts that are half-human and so on. The archetypes are very long-lasting in the Western tradition, and show up in other traditions as well: for example, the image of being swallowed by a whale as a symbol of hell appears in the biblical book of Jonah, in the novel, *Moby Dick*, in the children's story, *Pinocchio*, and in the second *Star Wars* film.

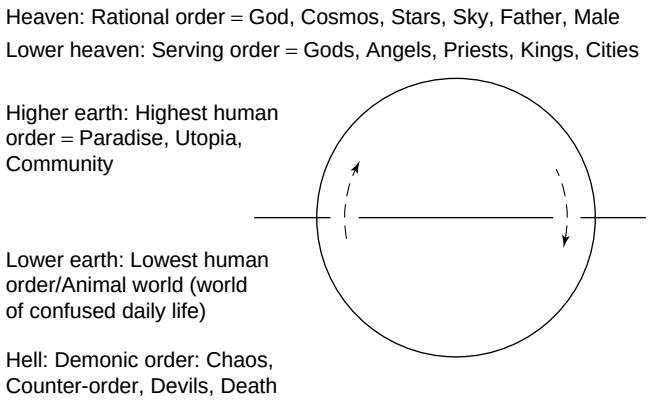

Figure 1 Ancient western cosmology [after Frye and others]

In other words, each mythological level clusters a range of images and symbols around itself, and one of the ways of identifying the kind of story one is in is checking out the symbols, images, and metaphors that pop up. It is not as simple as that, of course, because some of the images have changed over time, and have become used as parodies and ironies of themselves. But an initial grasp of how these clusters of images works is of interest, particularly as we continue to explore shifts in the images and ideas of Nature over time.

In the great Sumerian and Babylonian stories and epics, the hero journeys through the realms of darkness and of the gods, for a variety of reasons, including the need to tame the turbulent world to the purposes of humankind. Here is an excerpt from *Inanna's Journey To Hell* (from approximately 1500 BCE). Inanna was a powerful goddess in Mesopotamia. Inanna descends into hell during the dry season of the year, ostensibly to rescue her husband from death, but mythically to restore the natural cycle of life to the kingdom. Here is a brief scene of her return, with devils attached to her like leaches:

> Over the corpse hanging on a spike,
> They scattered the bread of life,
> They sprinkled the living water,
> And Inanna stood up alive.
> She will come up from the pit, but the Anunnaki
> (demons) seized her,
> The Judges said,
> Who has ever returned out of hell unharmed? •••
> She is coming, Inanna is coming
> from the pit! Devils are fastened
> to her thighs, devils walk beside her,
> meagre like reeds, thin as pikestaves.
> There goes in front of her a thing
> With a sceptre, but he is no minister •••
> She is coming, Inanna is coming
> From the pit!
>
> (trans Sandars, 1971)

The mythical quest of the female to restore health to an ailing kingdom is a widespread complementary story to the questing male battling more obvious threats to the kingdom (like monstrous beasts). In Egyptian myth, for example, the queen/goddess Isis has a King/husband Osiris, who is murdered by his brother Seth, and his body scattered around the world. The world loses coherence, and the kingdom withers. Isis travels the world, discovering and piecing the

fragments of Osiris back together again, and when he is fully restored, order and fertility returns to the land.

These myths of Inanna and Isis began to surface in the first millennium BC, and following the conquering of Egypt by Alexander the Great in the 300 BCE period, the myth of Isis in particular spread around the Mediterranean. A Greek equivalent was the myth of Demeter and Persephone. In this myth, Demeter, who was the goddess of fertility, has a daughter Persephone who is captured by the chief God of the underworld, Pluto. Demeter goes down into Hell to rescue her daughter, but discovers that her daughter has eaten six pomegranate seeds while being captured, which requires her to stay in Hell for six months of the year forever after. It is during those months that the world loses its fertility.

The Arrival of the Christian Story

These myths of Demeter, or of Isis the Eyptian, or of any number of other Gods, spirits, etc., were widespread in the ancient world until after the arrival of Christianity. The whole array of beliefs and stories is usually referred to as *paganism*, and what paganism means, generally speaking, is the worship of multiple gods, particularly in sacred natural places, like woods, forests and caves, and these gods often are the spirits of animals or powers in the world. As a reflection of the multiple cultures and multiple influences in the region, the stories and myths are themselves multiple, and often reflect a belief that the natural world is subject to constant surprise and transformation. Ovid's *Metamorphosis* (late 1st century, BCE) is a classical Roman expression of this widespread set of beliefs.

Somewhere around 1500 BC, a tribe of nomadic peoples, the Hebrews, were wandering around northern Mesopotamia. It is probably important that they were nomads, that is, that they weren't part of a rigid city culture, and didn't carry around with them statues or big pictures. They were saturated in the mythological culture of the region, but they developed a significantly different worldview over the next 700 years. The story of this evolution is told in the Old Testament, or Hebrew Bible (*see* Christianity and the Environment, Volume 5; Judaism and the Environment, Volume 5).

At the heart of this story is the idea of monotheism, which is more than just the idea that there is one God. Essentially, the Hebrews came to believe that they had a special God who had created the whole world and everything else in it, but was not Himself any part of that world. A central part of the idea is a radical questioning of what it means for something to have power – spiritual power. The Hebrews said, you people worship all kinds of Gods, animal gods, female gods, male gods, gods of fertility, etc. But what is the power that all these gods share? What is the power that gives them power?

There were other cultures that had a King of the Gods, Zeus, or Jupiter, but they were just more powerful versions of the other gods. What was the sacred power itself, which all these gods supposedly had? These were ultimately screens for the One True God, and could be done away with.

The second thing the Hebrews pointed out was that life with a lot of gods was confusing. You never knew which gods were on your side, and which were against you. You had to spend your whole day sacrificing to this god, and not forgetting that one, and so on. The Hebrews argued that it was ridiculous for people to be worshipping trees and animals: they should be worshipping the one true holiness that created the trees and the animals and gave them life.

This radical attack on the multiple natural gods of the ancient world was also part of the Hebrews' tribal strategy. When they entered what is now Israel/Palestine, which was then called Canaan, they proceeded to fight against all the local tribes, and part of their fight was against all the local gods, including the local versions of Ishtar, Baal, and other spirits.

The early books of the Bible capture the massive rethinking of Nature that went on in the creation of such a worldview. The upshot of the rethinking is that, in the end, though Nature can, and should, be seen as a glorious creation of God through which we might be able to get a glimpse of God's great wisdom and knowledge, it no longer has any intrinsic spirituality of its own. It is a vehicle for the greatness of God.

In the Hebrew Bible, we still get glimpses of the old tradition, some snippets about the old Canaanite religion, and a lot of complaining that pagan worship refuses to die; but by and large the Canaanite religion disappears from view as time passes.

It so happens that the Jewish people were only a minor player in the Ancient Greek and Roman world, so they were tolerated as being a bit eccentric. The God of the Hebrews joined the rest of the diverse array of gods and goddesses that peopled the Mediterranean.

All this changed with the arrival of Christianity.

When Jesus was crucified around 35 AD, He was originally thought of as just one more Jewish radical, but thanks to the efforts of, among others, a man who would later be called St Paul, who was both a Roman citizen and a Jew, Christianity began to spread around the Mediterranean. It took root because of its promise of individual salvation from death, and its intolerance for other religions. It was a bit like Microsoft: you can have no other operating system but mine.

Thanks to a series of events, culminating in the conversion of one of the later Roman emperors, Constantine to Christianity, Christianity became the most powerful religion in the Roman Empire, but unlike the other religions whose adherents were happy to let other religions flourish,

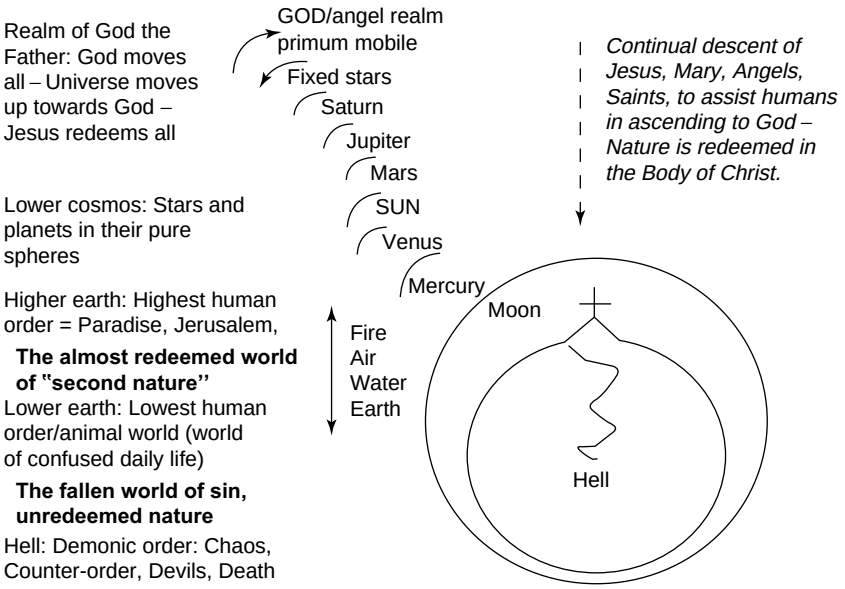

Figure 2 Medieval western cosmology. Primum mobile, the sphere that moves all other spheres [after Frye and others]

the Christians went on a 300-year rampage, destroying all the Roman cults, burning down the Great Library at Alexandria (associated with Isis), and hacking down all the sacred forests and groves associated with the pagan gods. Having done this in the Mediterranean, they then proceeded to do the same throughout Western Europe, culminating in driving underground the Celtic Gods of Ireland and the Norse Gods in Scandinavia.

This extraordinary story ended, in about the year 1000, with virtually the entire Western world being subject to Christianity. The central mythological and cosmological structure that had been extant before was now subjected to a strong narrative based on a single salvationary drive; i.e., the entire cosmos was part of a redemptive process whereby a fallen world – intensified by fallen human beings – was, at the end of time, to be re-perfected. The ideal Hero was Jesus, whose story became the template for the journey of Everyman through the world.

The early Christian literature, based on this very powerful vision of the spiritualization of the world, saw Nature as either irrelevant, or as a realm of symbols whose meaning was connected to the larger spiritual journey of the soul. In fact, Nature was seen as the realm of wilderness and danger, far removed from the realm of God. As this world view developed, it dovetailed with leftover astronomical and physical assumptions of the ancient Graeco–Roman world, which (for instance) argued that the Earth was the lowest realm, made up of the element Earth, and that the higher one went away from the Earth, the more one approached perfection. For example, the planets and stars in the heavens moved in concentric circles (actually, transparent spheres) around the earth, and so on. Again, as in the earlier cosmology (Figure 1), the higher you went, the more rational the world became, until you reached order and truth, God.

A map of this cosmology (Figure 2) shows the dimensions of the Medieval/Renaissance universe, and also the cluster of literary images that held together views of nature throughout that period. Our lower nature is subject to temptation; and the wild of the uncultivated natural world is a symbol of that temptation. This wilderness should be turned into a garden, or a farm, or ultimately a city, just as the soul should be cultivated.

In Dante's *Divine Comedy*, the hero (guided by Virgil, the ghost of the dead Roman poet), descends into hell, at the center of the earth, and reascends in the Southern Hemisphere, where he climbs the mountain of Purgatory, at the top of which he finds himself in a kind of paradise, like the original lost Garden of Eden. After this, he leaps up into space (guided by his long lost love, Beatrice) and rockets through space towards the ultimate place of God beyond the stars. This literary journey maps the whole natural and spiritual world of his time.

SECOND NATURE AND THE WINTER'S TALE

As already mentioned, one of the most important aspects of Shakespeare's work is that it appears just at the moment when the late medieval world view is being superseded by the early modernist world view. To repeat, Shakespearean literature (and that of his contemporaries and some successors) often operates according to metaphoric logic – categorization based on resemblance or co-incidence. A mandrake root was shaped like a human being, and therefore had influence over human beings. The

configuration of stars at one's birth was not an accident: the planets had different influences, as did different plants, animals, etc.

The importance of this is that the metaphoric view allows for a certain amount of positive valorization of natural nature, even in the medieval Christian period. An important medieval distinction was between *natura naturata* and *natura naturans* – nature more or less as a noun, and nature as a living verb, *naturing*. Shakespeare is fascinated by the power of nature naturing. Among the most interesting characters in his plays are bastards, who are always standing up and proclaiming their devotion to the raw powers of nature.

In the late Shakespeare plays, like *The Winter's Tale* (1613), nature (in one role) becomes something much more benign, and becomes tied to certain ambiguous functions of nature in literary art. The most obvious of these is the pastoral world of rustic shepherds and shepherdesses. Another was the garden. A third, and hardest of all to articulate, was the great benignness of Nature's rhythms in the world. In Shakespeare's late plays, there are tempests, bears, shipwrecks, etc., but one is constantly led to believe that it will all work out, that something is going on deeply in the world to reconcile everything. This is one reason why they all feel like fairy stories.

As the title suggests, there is a storylike quality to *The Winter's Tale*, and it is obviously haunted by winter (a season and a mood). In the scene excerpted below, a shepherdess greets two lords, who are searching for Prince Florizel, the heir to the kingdom, who has fallen in love with her. Unbeknownst to these lords, the shepherdess, Perdita, is herself a princess; they believe her to be a mere rural peasant. As with Ophelia in *Hamlet*, Perdita is fluent in the metaphoric language and etiquette of flowers. The scene opens with her gracefully giving rosemary and rue (and explaining their symbolism) to the two gentlemen. When they suggest that she is giving them winter flowers, she points out that she has avoided giving them nature's bastards – carnations and gillyvors. Because these plants were known for their genetic sports – their streaking and changes in patterns (piedness) suggested waywardness – they are symbols of nature's indiscriminate sexuality. Perdita is staking out civilized ground.

The next paragraphs provide a central discussion of the Renaissance view of nature and nature's art – what was called *second nature*. Second nature is what cultivation does: it takes the waywardness of nature and harnesses it to nobler ends. Perdita opens the discussion by using the term *art* for the process of creating nature (Natura naturans), and is naturally wary of it. Polixenes – who is about to denounce his son for fooling around with a mere shepherdess – brings in a different metaphor: the metaphor of grafting. In grafting, a branch of a growing tree is cut off and grafted onto another. The force of nature that continues the growth process eventually produces a next generation stronger and healthier than the earlier one. So Polixenes argues that human art can use nature's powers to improve nature. Thus, Shakespeare gracefully intertwines the theme of human cultivation and nature, with the irony that the supposedly rural shepherdess is herself a figure of the highest hidden art.

> Perdita: For you there's rosemary and rue; these keep
> Seeming and savour all the winter long:
> Grace and remembrance be to you both,
> And welcome to our shearing!
> Polixenes: Shepherdess – a fair one are you –
> Well you fit our ages with flowers of winter.
> Perdita: Sir, the year growing ancient •••
> The fairest flowers of the season
> Are our carnations and streak'd gillyfovers,
> Which some call nature's bastards; ••• and I
> care not to get slips of them ••• For I have heard it said
> There is an art which in their piedness shares
> With great creating nature.
> Polixenes: Say there be;
> Yet nature is made better by no mean,
> But nature makes that mean; so, over that art
> Which you say adds to nature, is an art
> That nature makes. You see, sweet maid, we marry
> A gentler scion to the wildest stock,
> And make conceive a bark of baser kind
> By bud of nobler race; this is an art
> Which does mend nature; change it rather, but
> The art itself is nature.
>
> (IV, III, 72–96)

ROMANTICISM AND AFTER

Beginning about the time of the Industrial Revolution, due to a variety of forces, the synthesized Christian–Ptolemaic cosmology began to collapse, and there arose a new cosmology, which we can call the creative, romantic, or revolutionary cosmology. This has remained with us ever since, and lives in uneasy relationship with the fragments of the earlier imaginative cosmology that still operate.

What happened was that the previous worldview, which was hierarchical – kings, priests, male centered, rule-oriented and rational – was no longer able to use the cosmology to support the existing power structure. The new emerging world of astronomical discoveries, the discovery of the new world, the new physics, etc., all confused the world picture; and during that period of confusion, there was also a widespread assault on hierarchical forms of government throughout Europe.

As a result, the world order of the people on top (let us now call it that officially) began to be attacked and parodied by means of a counter-cosmology. It is the persistence of both cosmologies – the official line, and the romantic line – that is essential to understanding how the myths and images of the modern Western world work, and especially modern *environmentalism*.

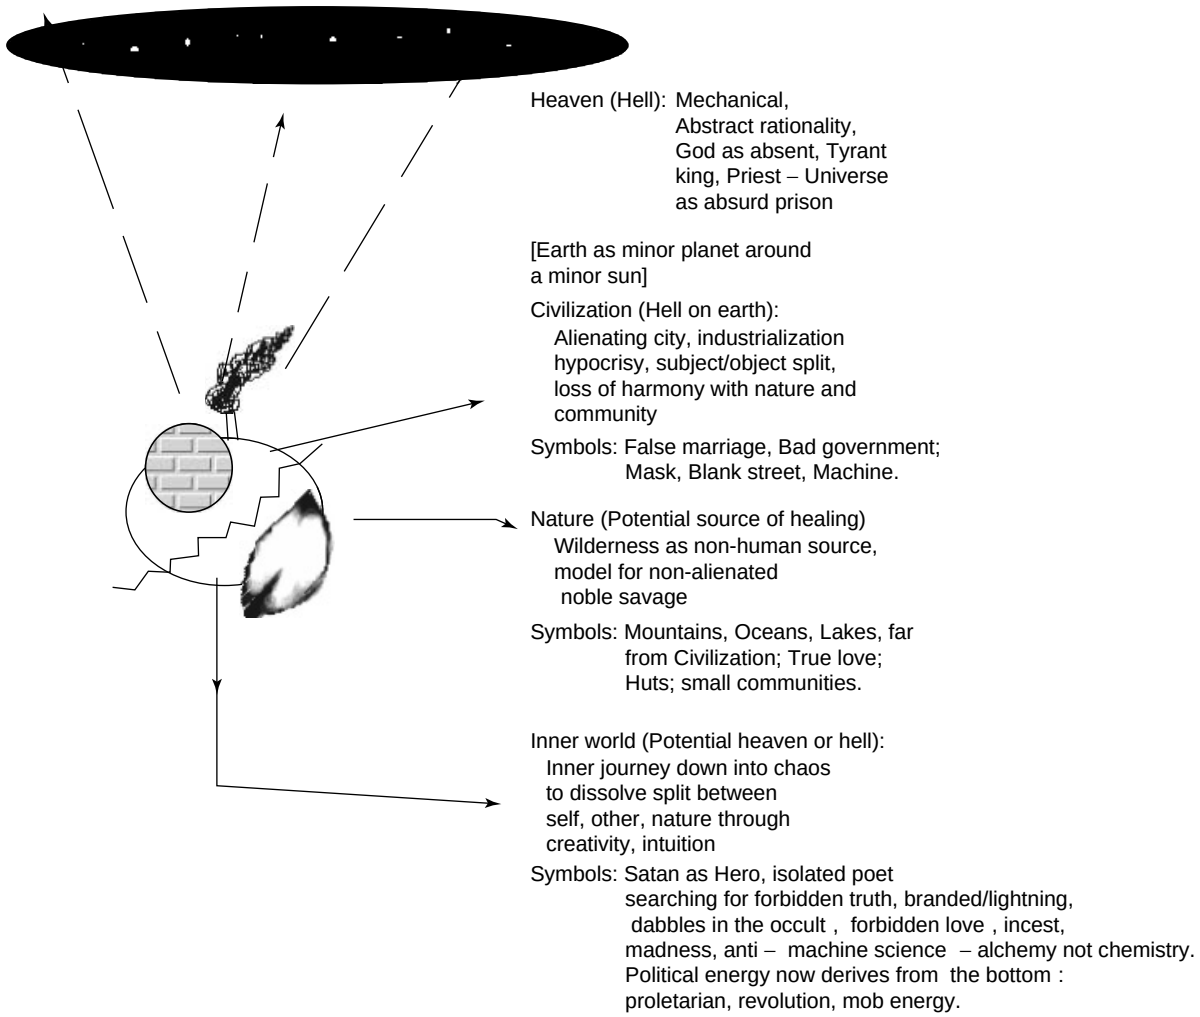

Figure 3 Modern cosmology/mythology/romantic parodic, countermyth

The Romantic countermodel broke through in a number of different places – it shows up in the American and French Revolutions, and has since been central for artists, musicians, environmentalists and others.

Let me describe a third cosmology (Figure 3), this time from the top to the bottom. It is somewhat less clear than the previous two. The reason is that one of the powerful things going on in the new cosmology is an attempt to parody and satirize the old cosmology. Remember that this is a cosmology, and a mythology, so the energy of it is carried through symbols, images, and metaphors.

To begin, the earlier world view was organized hierarchically, the higher you went, the more rational, ordered, and powerful you became, because you were getting closer to God.

The new worldview inverts and parodies this approach, because it no longer believes explicitly in the natural right of rulers to rule. This was one of the causes and outcomes of the American (1776) and French (1789) Revolutions.

The whole idea of the top becomes not the place you want to go to reach heaven. It is now the place of infinite space, the strange empty abstract cosmos ruled over by the laws of Isaac Newton. It is blank, inhuman, full of stars that no longer have any relevance to our lives. God has disappeared, turned into a puppet master or a watchmaker. This connects to a very powerful image of kings and gods not as reasonable beings, but as repressive rulers. The forces of authority are now thought of, not as spreading truth and reason from high places, but as being in charge of a repressive machine, designed to stifle human expression. Elements of this machine are increasingly seen as arbitrary creations of the repressive mind, and among the arbitrarinesses is the association of the masculine with the rational.

The next level down is the city of darkness, which is no longer the city of light, the holy organized rational city of Jerusalem. Rather it is the place of alienation, where faceless people work for the machine. This was particularly true in the first years of the industrial era, where the

whole structure of society was disrupted. Previously rural farm communities and family groups were uprooted and turned into workers. Workers, by definition, are gears in the machine. They have lost their humanity, and have become human resources.

The city is also associated with alienation, which shows up in the emerging idea of the lonely figure in the crowd. This becomes a powerful image in the new Romantic poetry of the 19th century. In William Blake's poem, *London* of 1794 we get some idea of this (William Blake, 1757–1827). Here are a couple of verses:

I wander through each chartered street,
Near where the chartered Thames doth flow,
And mark in every face I meet
Marks of weakness, marks of woe.
In every cry of every Man,
In every infant's cry of fear,
In every voice, in every ban,
The mind-forged manacles I hear.
How the Chimney sweeper's cry
Every blackening church appalls,
And the hapless soldier's sigh,
Runs in blood down palace walls.

And so on. The streets and the river are chartered – mapped, sold – and the human mind is now manacled, chained and shackled. The crisscross of square streets in the new modern city contrasts with the organic wandering streets of the medieval town. The city begins to grow, and to engulf its surroundings.

Similarly, just as human beings are being eaten up by the machine, so also is Nature being eaten up by the machine, and being transformed into objects. Power is the power over, the control over human beings and nature, which is created by having control over the wealth created by the machine, and this in turn is a creature of civilization.

Here is Blake again, in one of his late poems *Jerusalem*. A revolutionary poet is speaking:

O Divine Spirit, sustain me on thy wings,
That I may awaken Albion (Britain) from his long and cold repose;
For Bacon and Newton, sheath'd in dismal steel, their terrors hang
Like iron scourges over Albion: reasonings like vast serpents
Infold around my limbs •••
I turn my eyes to the schools and universities of Europe
And there behold the Loom of Locke, whose Woof rages dire
Washed by the Water wheels of Newton: black the cloth
In heavy wreaths folds over every nation: cruel works
Of many wheels I view, wheel without wheel, with cogs tyrannic
Moving by compulsion each other, not those in Eden, which,
Wheel within wheel, in freedom revolve in harmony and peace.

Here Blake summarizes his attack on the whole Industrial Revolution. He sees wheels without wheels (without here means outside of) as a mixture of clockwork, waterwheels, mechanisms imposed from the outside; as opposed to the organic development of wheels within wheels he sees in some future Paradise or Eden. The whole civilization has become poisoned.

For Romantic writers, it may be that progress was making people healthier and wealthier, but they were also being progressively pulled apart from each other, and from nature. Among the powerful Romantic themes was the idea of the *noble savage*, the very powerful idea that would haunt Romanticism from then on, which was that peoples, races, that were closer to nature were somehow better and wiser than people who belonged to civilization in general, and Western civilization in particular. The noble savage – identified with the increasingly marginalized indigenous peoples who were being chewed up by the new Western machine – was not alienated from his (or her) community, and had a special relationship with the natural world.

In contrast to them, civilized Man was split up the middle. Socially, naturally, and even in conflict with his own mind – for we begin to see that the mind-forged manacles may reflect the larger world view – a rational conscious mind/identity, alienated from one's own physical world.

If we go back to the cosmological chart, we can see this great split, which is rampant in the industrialized mind. For the Romantic writers and critics, this was the equivalent of a new *fall of man*, a tragic moment in human history against which they rebelled.

How is this split, these alienations to be overcome, or healed?

In the early Romantic era, there were two main answers, one political, and the other artistic, or creative. The political answer was revolution. Essentially what was required was for the mass of those being turned into machines to revolt and overthrow the masters on top.

Here we enter the next realm of the new cosmology: the idea that the bottom is the source of creative energy. It may look like the old hell, but it is where the next revolution would come from. Throughout the 19th century, and even in our own century, there is this image of the crowd, the mob, the mass of workers on general strike, like some dark force from a volcano, finally breaking through the stifling authoritarian machine towards some wider liberation which would finally sweep aside the old institutions. It was these images that were at the heart of the French and Russian Revolutions. The revolution from below was the force that would lead to the new heaven of Utopia. One of the starkest images that operated throughout the next hundred years was that of the blacksmith (and later the steelworker) working in the industrial equivalent of hellfire, with a hammer, striking blows for freedom in the midst of the dark factory.

This was the political answer. The split which was caused by repression would be overcome by the workers on the day

when they realized that the forces of repression were not just flimsy, but were being kept in power by their ability to keep the workers in ignorance of their true capacity to rule themselves without masters.

THE ARTIST AS RADICAL

A related answer, which moves us back into the details of our cosmology, was that Nature might become a source for a new regenerative force. If part of the symptoms of our problems could be seen in the destruction of Nature, and in the separation of the human from the natural, overcoming that split might also be relevant. Nature was naturally not human, so while it might be polluted, at its heart might be something different, which could regenerate the lost original human nature – again, sort of like repairing the original fall of man in the Christian tradition. Not only was nature not human, at least some parts of it could be seen to have an organic structure, one that naturally developed, rather than being imposed from the outside, by machine.

Again, notice that one of the important inversions of the previous cosmology is going on here. In the previous cosmology, wilderness was a place of chaos, of entanglement in irrational natural forces, leading one on to hell. In the new cosmology, wilderness, simply because it is not part of the machine, is a potential entry point into heaven, or at least paradise. The very fact that it is uncultivated makes it a starting point for the rebirth of a non-infected culture.

Also notice that it is the uncultivated, the non-rational, the pre-split in all its forms that becomes a source of new strength, of the divine energy of revolt. It is not a coincidence that we find in this period a new respect emerging for children, who come to be seen as unspoiled figures, not as adults in training (and modern educational theory dates from this early romantic period) – for aboriginal peoples – the noble savages I spoke of (we begin to get romantic stories like the *Last of the Mohicans*) – and the initial upgrading of women's voices that takes place in the opening of the 19th century with women like Mary Wollestonecraft.

Of equal importance is the rise of the artist, the creative person, the musician and poet, who represent the overcoming of the split between the mind and the world through their imaginations or their works. How does the artist, the musician, the creative person, overcome the split between the human and the natural?

There are two approaches that have become well known. One is associated with the image of the lamp. In this image, the idea is that the artist, through his or her creative mind illuminates and reaches out into the natural world, and overcomes the split through the power of new artistic power. We can hear this, for example, in the music of Beethoven, like his 5th Symphony, where the composer seems to hammer away (like a blacksmith) at the elements and forces of the world around him. This is an active approach (to say the least).

A second approach is for the artist or the poet to become more humble in the face of Nature – to become sensitive to the details and the rhythms of the natural world, to learn Nature's lessons. Over time, this cleansing of perception will reveal deeper truths of the universe to the artist. We can see this approach in the work of John Ruskin, who combined an environmental concern with a call for detailed analyses of Nature's designs in flowers, rocks, trees, and atmospheric phenomena.

These two approaches are often mingled together in different artists. When we look at a painting, like *The Sun owers* from the quintessential Romantic artist, Vincent Van Gogh, we cannot say whether Van Gogh was imposing his vision on the sunflowers, or saw them in themselves more deeply than we can.

In earlier cosmologies, the way you learned was by going up to high places, going to the city, finding a wise male leader. There were exceptions to this, but only part-exceptions: for example, in Dante's *Inferno*, the hero goes down into hell, but that is only the beginning of the journey up to the highest stars.

In the Romantic movement, we find that the idea of the journey down into the underworld in the previous cosmology, becomes the journey of discovery itself. This is because the new hell is caused by the repressive actions of the forces of order. The Romantic artist (and later versions of that, like the rock musician) goes out to the marginal peoples, down into the slums, away from the center of power. It is only there that the truth of repression is really to be seen for what it is. The people who live in the new hell are more liberated, because (in a parody of the earlier cosmology where the closer you got to God, the more rational everything became) the new cosmology argues that the farther you get away from authority, the more truth can be found. Since rationality is being imposed from the outside, irrationality may be more truthful than rationality. The madman may be saner than the doctor.

Lastly, the descent into a liberating new hell may be a descent into the personal hell, the unconscious mind. The poet, the musician, repelled by the repressive nature of modernity, descends into a variety of personal and social hells, and supposedly returns from that with new messages that will transform the world. The mythology of drug-ridden visionary rock musicians comes directly from this cosmology.

This descent into the mind may be echoed by the descent into the wilderness. The artist may go into the heart of darkness, go on a vision quest, seek out the truths that can only be found far from civilization. Inner nature and the natural world become linked, because both are on the run from the forces of human technological control. This helps

explain some of the attractiveness of the flight away from civilization into nature.

MODERNITY AND THE CONTEMPORARY ARTIST

These Romantic themes, and the dark cosmology that goes with it, have remained central tools in the hands of writers and artists. Much of the literature of the 20th century explored the themes of the alienating environment of the city, the potentially liberating, but also potentially dangerous, voyage into the natural environment, and the journey of the hero and heroine into inner nature. A novel like George Orwell s *1984* paints the environment of the city as alienating, repressive, and one without any hope. The only time that the characters nd any liberation is when they escape to Nature, temporarily. The same is true in Aldous Huxley s *Brave New World* and many other powerful indictments of contemporary life.

A new theme that has emerged in literature since World War II, and is paralleled by the rise of the environmental movement, is the possibility raised by nuclear war of the elimination of all life on earth. For writers, this has been inescapably linked to the experience of the death camps of Auschwitz and Birkenau, where the whole question of civilization came under question. The German critic, Theodor Adorno, famously said that one could no longer write poetry after the Holocaust. The dark hole of that experience sucked the life out of the pretense of words. Since then, writers have been constantly haunted by threats to the fabric of life; and this has shown up in the themes and characters they write about.

Nevile Shute s *On The Beach* (1959), which portrayed the consequences of the global spread of nuclear fallout, has a good claim on being the rst modern environmental novel, saturated with the themes just outlined. Of increasing interest in recent years has been the strength of non- ction writing about the environment, re ecting in part the presence of large amounts of scienti c or naturalistic fact in contemporary life. Writers like Gary Snyder (*Earth House Hold*) and Annie Dillard (*Pilgrim at Tinker Creek*), anthropologists like Richard K Nelson (*Make Prayers to the Raven*), biologists like Sandra Steingraber (*Living Downstream*), and farmers like Wendell Berry (*Home Economics*) grounded their environmental writings in exemplary detail, and often used them as springboards for moments of personal discovery.

CONCLUSION: AND DEATH, TOO, IS IN ARCADIA

In searching for a piece of recent writing about the environment to conclude this essay, I decided to use the example of a poem, written by myself, and published in the mid-1980s. I choose it, not because it is a great poem, but because as the author, I can speak to it somewhat freely as to the intentions and sources of its creation, and how it was intended to relate literary forms to environmental changes. This may give some insight into the literary process (or at least one writer s process).

The poem was part of a suite of poems called *The Fate of the Earth and Other Poems* published in the Canadian environmental magazine *Probe Post* (Timmerman, 1988). This particular poem draws on the literary tradition called *pastoral*, which was used in *The Winter s Tale*. It was a sophisticated Greek and Latin form of verse (and sometimes prose) about simple shepherds in rustic landscapes, either singing about the joys of the rural life, or complaining about a shepherdess who would not love them, or the troubles of farmers in an uncertain world. Many writers Virgil, Horace, Pope, Shakespeare, Sidney used this form, often disguising criticism of mainstream urban society under the guise of simple unlearned folk. There was also a kind of utopian dream associated with this simplicity, which was classically located in a place called Arcadia in Greece.

Accompanying the poem was a photograph of a famous painting by Nicholas Poussin (*see* **Art and the Environment**, Volume 5) called *Et in Arcadia Ego*. The painting shows a group of shepherds in Arcadia huddled around a large tomb upon which are carved the words *Et in Arcadia Ego*, which is a reference to death. That is translating from the Latin *I Too Am In Arcadia*. Naturally, this means that there is no escaping from death, not even in the beautiful natural simplicity of Arcadia.

With this introduction, here is the poem:

And Death, Too, is in Arcadia

The house of Nature sags against the rain.
The sap fails in the sugar maples, and the
cry of the waterbirds fades like mist
over morning by grey, secret inlets.
The rustle of wind is the whisper of weeping.
There is Death in the woods, lling the air,
down along the marshlands, dropping
out of the once benevolent skies, shedding
hot tears of helpless pain.
The webbing of life tears and drifts apart:
poison pulses from the snow, and
the land soils itself into the stream, and
the lake slowly wearies of all its children.
Against its own, its deepest rhythm dying,
Nature screams and warps against the grain.
And look, here, look
here in the depths of faltering Arcady,
even the gravestones dissolve in grief
at things never seen or heard before
in any version of pastoral.

The poem was written in the speci c context of acid rain, but also more generally in relation to a world in which

things that naturally symbolize goodness, like rain and mother's milk, are turned into poisons. There is a strange situation where the natural processes are turned against themselves, and the deep rhythms of nature are warped by the influence of human chemical poisoning.

One important aspect of the poem is that, like the distant lakes and waters affected by acid rain, Arcadia is far away, and yet affected by long-distance transport of pollutants. I carefully used images and ideas from the scientific literature on the loss of leaf cover, stresses on trees, loss of water birds, early snowmelt at the beginning of the year that pulses acid into lakes just at prime birth time for fish, and so on. However, there is an even stronger connection to one powerful theme in the pastoral poetry tradition: the mourning for the lost shepherd.

In the English poetry tradition, the most famous example of this theme is John Milton's poem *Lycidas* (1642). In this poem, which mourns the loss of a young poet who was drowned at sea, the whole of nature is bidden to mourn as well for the loss of one who loved nature:

> With cowslips wan that hang the pensive head,
> And every flower that sad embroidery wears.
> Bid amaranthus all his beauty shed,
> And daffadillies fill their cups and tears,
> To strew the laureate hearse where Lycid lies.

This is a classic example of what was discussed earlier with reference to *Julius Caesar* where the sympathies of nature for human beings are assumed.

In my poem, I was trying to evoke the images of the dying poet, but with a modern twist, to evoke the dying of nature, and also to suggest that this was something new in the history of the world (never seen in Arcadia or anywhere) – the possibility of the dying of nature. An oblique reference is made to a famous book on pastoral by the literary critic William Empson, *Some Versions of Pastoral* (Empson, 1935).

Also, among the guiding images of the final lines of the poem is that of sculptures and tombstones that I had seen in city graveyards that had been worn down by air pollution over the years, and were themselves symbols of the destructiveness of contemporary environmental problems.

A brief technical point, which may highlight the way in which, in a poem, everything matters, including the form as well as the content, is that I used a number of what are called *weak endings* – where the rhythm of the word is such that there is a strong beat on the first half of the word, and a weak, falling off rhythm at the end – words like weeping, dropping, filling, shedding – so as to evoke sadness and loss. There are also lines like the rustle of wind is the whisper of weeping that are meant to give the reader the sound of the wind in the threatened woods.

These kinds of considerations – and many others – go into the response of those who write literature today in the face of the environmental crisis.

Love Canal

Love Canal was the name given to a suburban subdivision in Niagara Falls, NY. Residents first became aware of their proximity to toxic waste through a *Niagara Gazette* newspaper article by Michael Brown in April 1978. Local

housewife, Lois Gibbs, quickly emerged as the key organizer of a community riddled with fears for their health. She initially began a petition campaign to close the 99th Street School, built in the virtual center of what had been the dumpsite, abandoned by a subsidiary of Occidental Petroleum.

By August 1978, the New York Commissioner of Health declared a state of emergency and ordered the closing of the school. Within days, US President Jimmy Carter declared an emergency and provided funds to permanently relocate 239 families living within the first two rows of homes closest to the former waste dump. The community campaigned for the relocation of all 900 families.

In May 1980, the US Environmental Protection Agency (EPA) released results from blood tests of residents showing chromosome damage. Love Canal activists took two EPA officials hostage. On May 19th, Lois Gibbs issued an ultimatum: commit to relocating all Love Canal residents by noon May 21, or What we've done here today will look like a Sesame Street picnic to what we'll do then. The White House agreed to permanent relocation by the deadline.

Occidental Petroleum has paid nearly $250 million (US$) to compensate residents and reimburse state and federal government clean-up costs. In 1990, the EPA announced that sections of the area were safe for resettlement.

The controversy is credited with sparking the EPA's Superfund Programme.

M

Malthus, Thomas Robert

(1766- 1834)

Thomas Robert Malthus, clergyman, professor, political economist, was born in Great Britain to a well-to-do country family. He studied mathematics at Cambridge, and was ordained a minister at the age of 22. Malthus served as a clergyman and as professor of modern history and political economy at Haileybury College. His ideas and eventual economic philosophy were molded in part by the debates he had with his father, who held optimistic views of human progress. Malthus himself saw social problems growing in exponential terms.

Malthus' views of the economic and social implications of population growth were contrary to the common economic assumptions of the day. Most viewed population growth as being a positive by-product of economic growth and social advancement. In 1798, Malthus published his *Essay on the Principle of Population* (there were seven editions in all). In the essay, Malthus held that while population grows exponentially, the availability of food and other resources grows arithmetically. But population would be held in check by periods of plague or war. Technological advances would provide periods of social stability, until the power of exponential population growth again resulted in too many people for available resources. Social discord would inevitably return.

An essential point in Malthus' argument is that in the long-run, population would always tend to remain above the level that resources could adequately support. Malthus wrote in his essay that population is constantly acting upon man as a powerful stimulus urging him to the further cultivation of the earth, and to enable it to consequently support a more extended population. In addition to the pervasive impact of population on human cultural conditions, his theory also alludes to the existence of a static stock index. This index holds that there are absolute limits to resource availability and limits to the positive affects of human innovation. It was in this realm of thought that he maintained an ongoing debate with his friend David Ricardo. Though Ricardo agreed with the Malthusian notion of population growth, he disagreed with the implications. Ricardo argued that technological innovation, substitution, and the discovery of new resources would be the inevitable cultural responses – in essence the stock index was neither static nor binding.

The Malthusian notion of scarcity and population also contributed to a theory of wages (iron law of wages, or Malthus' law of wages). This proposed that an increase in the wage rate results in an increase in population, this in turn depresses wages, and thus wages remain mostly at a subsistence level. His theological background was reflected in his economic and social thought. Famine and poverty were certainly seen as natural, and hence, divine outcomes. He also believed that moral constraints (abstention from sex) were an essential part of addressing population, though he had doubts about the practicality of this solution.

The ideas of Malthus were refined within the neo-Malthusian tradition. In this realm, the idea of absolute scarcity and the exponential impact of population growth have been quite attractive to ecologists, and to many in environmental movements. Such perspectives see a strong relationship between the geometric impact of economic and social consumption, and absolute limits inherent in nature.

Man and Nature as a Single but Complex System

Michael Thompson
The Musgrave Institute, London, UK and The University of Bergen, Norway

No matter how lightly we tread on the Earth, we cannot avoid altering it. And, as it alters, so the way we tread on

it - our ecological footprint, as it is sometimes called - is, in turn, altered. On and on. Natural scientists tend to look at this interaction of the human and the natural from the Earth's perspective, The Earth as Transformed by Human Action *(Turner* et al.*, 1990) being the classic text. Social scientists tend to look at the interaction from the socio-cultural end:* Living with Nature *(Fischer and Hajer, 1999), with its subtitle* Environmental Politics as Cultural Discourse*, is a recent example. But can we go further? Can we push each of these approaches (the natural scientist's and the social scientist's) to the point where they actually meet and give a single, uni ed theory of our relationship with nature?*

Yes we can, chorus two schools of thought: one sociological, the other ecological. The rst has its roots in social anthropology and is, properly speaking, a theory of socio-cultural viability (but, since that is too much of a mouthful, it has been shortened to Cultural Theory, with the capital letters serving to distinguish it from other theorizing about culture). The second has emerged from natural resource ecology, where those whose interest is in grasslands, sheries, forests and so on encounter the institutions that are doing the exploiting and the managing, not as organized arrangements of people and their various convictions as to how the world is, but as patterned interventions in the ecosystems they are studying.

In this article, we describe a uni ed theory, and some of its implications for policy.

A ROAD WITHOUT END

The classic assumption, in both ecology and social science, is that there is a one-way transition from state A to state B. In ecology, the process of succession (Clements, 1916; Odum, 1969) ensures that an initially unstructured state of affairs (one huge niche filled with anarchic, opportunistic and competitive organisms (the r-strategists)) is steadily transformed into a climax community: a structured and stratified arrangement of diversified niches, with clearly defined interrelationships between the species (the K-strategists) that occupy them (*see* r–K Strategies, Volume 2). In social science, this predictable, linear and equilibrium-seeking model of change is paralleled by a number of grand theories in which some inexorable logic moves us all from mechanical to organic solidarity (Durkheim, 1893); from community to society (Gemeinschaft to Gesellschaft, Tonnies, 1887); from traditional to modern (Weber, 1922); from status to contract (Maine, 1861); from capitalism to communism (Marx, 1859); or, as modern theorists of institutions put it, from markets to hierarchies (Lindblom, 1977; Williamson, 1975). Different masters may define their A's and their B's differently, but all subscribe to a two-fold scheme and to some driving force (such as rationalization, internal contradiction, or spiraling transaction costs) that carries the totality from A to B.

These transitions, whether ecological or socio-cultural, are all in the direction of more orderliness, more differentiation, more connectedness, and more consistency and, once they have gone as far as they can go in that direction, that is that. In other words, these models of change end up making change impossible. Of course, something on the outside may intervene and mess things up, thereby setting the whole thing in motion once more but, left to themselves, these models get ecosystems and socio-cultural systems from A to B and then stop. Change, these models tell us, is a temporary phenomenon.

These models are beginning to be seen as less than satisfactory. They explain change by getting rid of it, and they are increasingly incapable of making sense of what is actually going on. They have now been challenged by models that are indeterministic (i.e., more than two-fold) and make change a permanent and essential feature of existence: the four-fold institutional scheme proposed by Cultural Theory (Thompson *et al.*, 1990) and the four-fold ecocycle advanced by Holling (1986). If social and ecological systems are as these models say they are, their interaction will inevitably result in complex and non-linear dynamics, giving an unpredictable, always out of equilibrium, and never ending sequence of transitions between multiple states. And none of these will ever be the end of the road.

In the classic social science formulation, two kinds of solidarity interact. *Markets* are the competing players, all merrily bidding and bargaining with one another; *hierarchies* are the benign authorities who ensure that the various conditions for playing of this trading game (a level playing field, for instance) are in place. Cultural Theory does not reject this foundational distinction. Rather, it argues that there is more to life than just markets and hierarchies and that you will lay yourself open to all sorts of unwelcome surprises if you go on assuming that hierarchies and markets explain it all. Take, for instance, the Brent Spar oil storage structure.

If there were only markets and hierarchies, then the solution that was agreed between Shell (the market actor) and the British Government (the hierarchical actor) would have come to pass, and the Brent Spar would now be mouldering in its watery grave (*see* Brent Spar, Volume 5). It is not; it is sitting bolt upright in a Norwegian fjord. Greenpeace, an actor from a third kind of solidarity (we call it *egalitarianism*), winged its way in, literally, and totally transformed the outcome. Since this was written, a final decision (negotiated between Shell and Greenpeace) has been reached, and the structure is now being cut up into cylindrical sections to a roll-on/roll-off ferry terminal in Norway.

Nor is it just Brent Spars that cause trouble for the simple markets and hierarchies approach. A recent analysis of how things are actually done in Himalayan and Alpine villages (Price and Thompson, 1997; this article is based, in large part, on this 1997 paper, which has a more extensive set of references than is included here) strongly suggests (as we will see in a moment) that, if these mountain farmers relied on just markets and hierarchies, neither they nor their environments would be the way they are. Nor is this inadequacy of the markets and hierarchies framework confined to economically marginal mountainsides.

The ills of the American city have recently been blamed on the public-private partnerships that were seen as the solution (Brion, 1992). Hierarchies and markets, in coming together in this cozy and unseemly way, have totally excluded community (the egalitarian solidarity) and forced the citizenry into a state of atomized, alienated subordination and systematic exploitation (*fatalism*: the fourth and rather passive, solidarity that completes the typology).

At the global level, the three active solidarities (markets, hierarchies and egalitarianism), altogether with the markedly different problem de nitions and solution de - nitions that each of them generates, are clearly discernible in the climate change debate. Indeed, they are what make that debate possible, each voice all the time de ning itself in contradistinction to the other two. Hierarchists pin the blame on population. Individualists (the supporters of market solidarity, which Cultural Theorists call individualism) see it as stemming from people being able to treat the environment as a free good. Egalitarians insist that it is pro igacy (excessive consumption, especially in the richest nations of the world) that is the root of it all.

Their solutions essentially, reduce population (hierarchy), get the prices right (individualism) and frugality (egalitarianism) are so divergent that each constitutes part of the other two s problems. Frugality, it turns out, requires the abdication of capitalism: the driving force of the individualist s solution. The population diagnosis, as far as the egalitarians are concerned, blames the victim (the South, which is where all the population growth is), and lets the guilty party, the North, off the hook. And the sorts of market interventions that both the hierarchists and the egalitarians, in their different ways, are intent on will, the individualists insist, get the prices even more wrong than they are at present! (See Chapter 4, Vol. 1 of Rayner and Malone, 1998, where the self-organization of these three voices is set out by means of a painstaking discourse analysis).

This means that human interactions with the environment cannot be effectively analyzed using theoretical frameworks that allow just one or two positions. Such frameworks are insuf ciently variegated.

This is the main practical message from Cultural Theory, and it is a highly discomforting message for policy makers generally and, in particular, for those who build the computer-based models that underlie most policy making within the broad area that is now labeled sustainable development.

In most of these models, the representation of the micro-level, the household (in energy modeling) and the farmer (in land-use modeling), is singular: an economically rational utility maximizer. Such a representation recognizes just one voice (that of individualist solidarity) and silences the other two.

More recently, modelers have progressed to the classic formulation and recognized two of the voices. The International Geosphere Biosphere Programme Land-Use and Land-Cover Change (IGBP LUCC) project (*see* **IGBP Core Projects**, Volume 2), for instance, notes that land-use and land-cover change is taking place increasingly under the in uence of the market, and that this justi es a model based on economic theory: a decentralized setup in which all agents individually solve their inter-temporal maximization problems, consumers maximizing utility, rms maximizing pro ts and so on. If the markets are competitive, so the argument runs, these agents can take prices as given, but in those instances where markets are not competitive, the optimization has to be done by government or some other higher level authority. But the third voice (that of egalitarian solidarity) is still excluded, leaving the policies that such models underpin wide open to the sorts of nasty surprises that have overtaken Shell and the government in Britain and the public private urban regeneration partnerships in the United States.

Two-voice modeling, though an improvement, is still insuf ciently variegated. Like one-voice modeling, it is still wedded to optimization and managerial control, when what is needed is constructive negotiation between all the voices: the democratization, in other words, of decision processes that have been depoliticized and treated as merely technical. This is a topic that, since the debacles over mad cow disease (bovine spongiform encephalopathy) and genetically modi ed crops in Britain, the dismantling of the Millau MacDonald s by the French sheep farmer Jose Bove, the Battles of Seattle and Prague (vehement demonstrations against the World Trade Organization), and a host of similar events around the world, is increasingly on national and international agendas. But, to actually do that democratizing, we have to avoid silencing any of the voices, and that is something that current approaches, being insuf ciently variegated, cannot do.

To help clarify what sort of differences a suf ciently variegated framework makes, and to gain a more re exive

(personal) understanding of what is going on in our own social systems and environments, we can take a close look at the surprisingly complex lives of the seemingly simple folk who live in the Himalayas and the Alps. These people, Cultural Theorists would point out, know something that the single problem-single solution merchants who tend to dominate policy-making in advanced industrialized societies have managed to forget.

Solidarities in Action

Himalayan villagers parcel out their transactions with their physical environment into four distinct solidarities, each of which is characterized by a distinct management style. Agricultural land, for instance, is privately owned whilst grazing land and forests are communally owned. But grazing land and forests do not suffer the tragedy of the commons (*see* Commons, Tragedy of the, Volume 5; Property Rights and Regimes, Volume 5) because transactions in their products are under the control of a commons' managing institution. Villagers appoint forest guardians, erect a social fence (a declared boundary, not a physical construction) and institute a system of fines for those who allow their animals into the forest when access is forbidden, or take structural timber without first obtaining permission. If the offender is also a forest guardian, the fine is doubled; if children break the rules, their parents have to pay up.

Informal though they may seem, and lacking any formal legal status, these arrangements work well in the face-to-face setting of a village and its physical resources. Drawing on their home-made conceptions of the natural processes that are at work (their *ethnoecology*), the forest guardians regulate the use of these common property resources by assessing their state of health, year by year or season by season. In other words these transactions are regulated within a framework that assumes, first, that you can take only so much from the commons and, second, that you can assess where the line between so much and too much should be drawn. The social construction inherent to this transactional realm is that nature is bountiful within knowable limits. This, to make a link with the ecological theories of Holling (1986), is the myth of *nature perverse/tolerant* (Figure 1).

With agricultural land, however, decisions are entirely in the hands of individual owners, and fields (unlike communally owned resources) can quite easily end up belonging to the moneylenders. In recent years, when forests and grazing lands have suffered degradation (for a variety of reasons, not the tragedy of the commons), villagers have responded by shifting some of their transactions from one realm to the other. For instance, they have allowed trees to grow on the banks between their terraced fields (thereby reducing the pressure on the village forest) and they have switched to stall feeding their animals (thereby making more efficient use of the forest and grazing land and receiving copious amounts of manure which they can then carry to their fields). In other words, transactions are parceled out to the management styles that seem appropriate and, if circumstances change, some of those transactions can be switched from one style to another.

Since they are subsistence farmers, whose aim is to remain viable over generations (rather than to make a

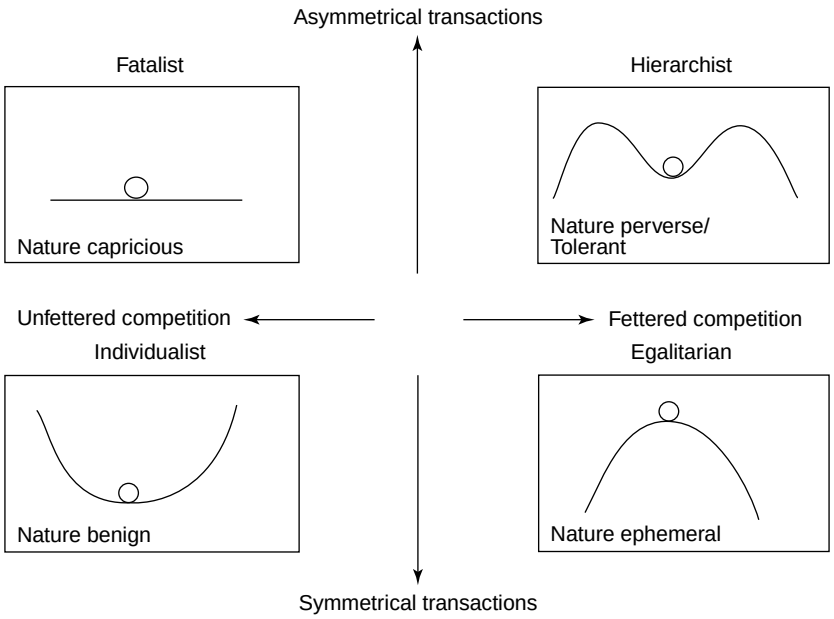

Figure 1 The Solidarities, their myths of nature and their transactional realms

killing in any one year) their transactions within their local environment can be characterized as low risk, low reward. However, during those times of the year when there is little farm work to be done, many villagers engage in trading expeditions, or in migrant labor in India. Trading expeditions are family based, family financed and highly speculative: high risk, high reward. So a farmer's individualized transactions, when added together over a full year, constitute a nicely spread risk portfolio. The attitude here (and particularly at the high risk end of the portfolio) is that Fortune favors the brave, Who dares, wins, There's plenty more fish in the sea . Opportunities, in other words, are there for the taking. The idea of nature here is optimistic, expansive and non-punitive: *nature benign* (Figure 1).

Social scientists in general, and institutional economists in particular, would see these two realms as corresponding to their classic distinction between hierarchies and markets, and would have no difficulty in explaining the processes by which some transactions are switched this way or that (though they would be surprised to find that the hierarchy was a village-level commons managing institution, not the state). But (and this is the essence of the Cultural Theory argument) hierarchies and markets do not exhaust the transactional repertoire of the Himalayan villager. Some collectivized transactions do not involve formal status distinctions (such as those between forest guardians and ordinary villagers) and some individualized transactions are marked by the absence of bidding and bargaining (an essential characteristic of the markets that are generated by the individualist solidarity). The plurality, in other words, is four-fold, not two-fold.

In many parts of the Himalayas (especially the Indian Himalayas), village autonomy is always under threat, because powerful outside actors are also laying claim to the forest resources that are so vital to Himalayan farming systems. One very effective response to this external threat has been the Chipko Movement (*see* Chipko Movement, Volume 5). This is a grassroots and highly egalitarian social movement, in which women (who are largely responsible both for fodder gathering and fuelwood collection) predominate. *Chipko* means to stick, and the Gandhian strategy is to physically hug the trees, thereby preventing them from being appropriated. Those villagers of a slightly less non-violent disposition actually chase the logging contractors (and the government forestry officers who have been corrupted by the contractors) out of the forest with their *kukris* (long curved knives). In the Narmada Valley, farther to the south (where a vast development project is under way), they have now done the same to the representatives of the World Bank: a South Asian counterpart to the Brent Spar surprise. (Indeed, the World Bank pulled out in 1993 but the project is still being promoted by Indian State Government and market borrowings.)

So far as these threatening external transactions are concerned, it is certainly not a case of plenty more fish in the sea , nor is there even a safe limit, within which the commercial extraction of timber would be sustainable. All external predation is seen as catastrophic in its consequences. Hence the spectacularly uncompromising collectivist response of the tree huggers, whose idea of nature is one in which any perturbation of the present low-key regime is likely to result in irreversible and dramatic collapse: *nature ephemeral* (Figure 1).

Finally, in every village, we may be sure, there will always be some people who sneak wood from the forest when no one is looking, who can never quite get together the capital, the contacts and the oomph to go off on trading expeditions, and who manage somehow not to be around when it's all hands to the tree hugging. These are the fatalists: people whose transactions are somehow dictated by the organizational efforts of those who are not themselves fatalists. Theirs is a life in which the world is always doing things to them (sometimes pleasant, sometimes unpleasant) and in which nothing that they do seems to make much difference. Why bother? is the not unreasonable response of the fatalist. If that is how the world is, then learning is not possible and, even if it were, there would be no way of benefiting from it. The idea of nature here is one in which things operate without rhyme or reason: a flatland in which everywhere is the same as everywhere else: *nature capricious* (Figure 1).

From Simple to Complex

Completing the typology with these two solidarities (egalitarianism and fatalism) makes some important differences. For instance, once we understand egalitarian solidarity, we can avoid the sorts of surprises that have been visited upon the Brent Spar and the Narmada River Project. And we can see that, only if all the transactions are in the fatalistic realm (the one realm where learning is not possible), would the prevalent assumption (evident, for instance, in the hierarchist's diagnosis of the climate change problem) and the IPAT equation (*see* Modeling Human Dimensions of Global Environmental Change, Volume 5) that there is a direct relationship between population increase and environmental degradation hold true. But there is much more to it than this.

Change, in the conventional theory, is deterministic. If you're knocked out of hierarchy, you'll end up in the market, and *vice versa*. But, in Cultural Theory, change is indeterministic: leave A and you can end up at B, C or D, and when you leave whichever one of these you have arrived at, there are three possibilities, on and on.

Conventional theory treats human systems as simple (linear, deterministic, insensitive to initial conditions, equilibrium seeking, and predictable); Cultural Theory treats them as complex (non-linear, indeterministic, sensitive to initial conditions, far from equilibrium, and unpredictable).

Simple systems are manageable in the sense that, once we understand enough about them, we can define some desirable state of affairs (*sustainable development* is the current favorite) and then steer the totality towards it. But this, as our next example makes clear, is not possible if the system is complex.

A Swiss Example

Moving from the Himalayas to the Alps, we nd much the same four-fold allocation of transactions, with agricultural land being privately owned and grazing land (and sometimes the forests) being communally owned. But the Swiss forests, unlike those of the Himalayan villagers, are physically sandwiched between the high pastures (communally owned) and the valley oor (privately owned elds, houses and hotels). Over the centuries that the Davos valley has been settled, to take a speci c locality, both the elds and the grazing land have expanded at the expense of the forest. The trees on the steeper slopes have stayed in place, acting both as a source of timber and as a barrier against avalanches. However, it is dif cult to achieve both these functions simultaneously. The Davosers have often set in train changes in the forest s age structure which, decades later, have resulted in exceptional avalanches reaching the valley oor and threatening the destruction of the entire community.

Every time this unpleasant surprise has befallen them, the Davosers have responded by switching their forest management onto the all in the same boat egalitarian style. Later, it has sometimes shifted to the hierarchist style, often to the individualist style (with farmers owning long thin strips of forest running all the way from valley oor to alpine pasture), and sometimes to the fatalist style (as happened, for instance, when the avalanche danger was clearly perceived yet extraction continued in response to the demands of various mining booms and, in more recent years, the demand for ski-runs).

Surely, you might think, they would have got it right by now. To think that is to assume that there is one right way; but as Cultural Theory shows us, that is not the case. There is no way of ever getting it right, because managing one way inevitably changes the forest, eventually to the point where that way of managing is no longer appropriate. This would happen even if there were no exogenous changes (like the mining and tourist booms) which, of course, there always are (even in seemingly remote places like the Himalayas). Viability can only be achieved, therefore, by covering all the bases: by the villagers ensuring that they have the full four-fold repertoire of management styles, and by their being prepared to try a different one whenever the one they are relying on shows signs of no longer being appropriate. The Davosers, like their Himalayan counterparts, have now been in their valley for more than 700 years, without destroying either themselves or their valley in the process. This achievement would not have been possible if they had opted for just one management style, or even for the two that the prevalent orthodoxy allows!

Multi-vocality

Himalayan and Alpine villages, with their transactions parceled out in these four very different ways, are impressively multi-vocal. More than that, as is evident from the examples of stall feeding and trees on private land (in the Himalayas) and of alternative forest management styles (in the Alps), they have the ability to switch transactions from one way to another whenever it seems likely that this might be more appropriate. Since the behavior of the villagers is continually altering the resource base on which they depend, their villages would not be viable if they did not have this in-built (messy, noisy and argumentative) mechanism. Schapiro (1988) has dubbed this sort of setup (in which each conviction as to how the world is, each myth of nature, is given some recognition) a *clumsy institution*. This is in contrast to those more elegant, and more familiar, arrangements (tidy, quiet and suavely consensual) in which just one conviction holds sway. The terminology is deliberately counter-intuitive, clumsy institutions having some remarkable properties that are not shared by their unclumsy alternatives.

To understand just how remarkable clumsy institutions are, imagine for a moment that you are some God-like experimenter, able to reach out and change this is or that variable in a Himalayan village s environment, or to move it bodily east or west, north or south, across the convoluted landscape. As you bring in the logging contractors, or take it 100 km eastwards or 1000 m higher, the village will shift its transactions this way or that between its four options until it has adapted itself to its changed circumstances. In other words, it will maintain its viability thanks to the very practical learning system that is part and parcel of its four-fold plurality. If the village did not have this plurality, and was an elegant and unclumsy institution, like many national forestry services, including Britain s Forestry Commission (Tomkins, 1989) and the United States Forest Service (Hirt, 1994), it would not be able to do this. Something along these imaginary lines, it turns out, is what has actually happened, and continues to do so.

As we go from one Himalayan village to another, the relative strengths of the four ways of organizing vary. Egalitarianism, for instance, is strongest in those parts of the

Himalayas that are most prone to commercial logging. As one moves eastwards, from India (with its powerful center and its colonial heritage of Reserved Forests) into Nepal and Bhutan, so the Chipko Movement and its counterparts become less of a force to be reckoned with. If the inequitable external threat is absent then so too, it appears, is the communitarian response to it. However, the most dramatic of these variations is north–south: between the strongly individualized Buddhist villages and the strongly collectivized Hindu villages a day or two's walk downstream. These are Furer-Haimendorf's (1975) adventurous traders and cautious cultivators, respectively: apt characterizations which readily map onto two of the four social beings (individualists and hierarchists, respectively) that we have described above.

Cultural Theorists, we should explain, use the term *social being* to describe the behavior to which an individual must conform, and the convictions that he or she must espouse, to help maintain the form of social solidarity to which he or she belongs. The prime mover, therefore, is not the individual (the psycho-physiological entity) but the form of social solidarity. Thus, the terms hierarchist, individualist, egalitarian, and fatalist denote available roles (or management strategies) that individuals step into, or out of, as their daily lives, or the changing seasons, take them from one transactional realm to another (Figure 2). (See also Box 1: A Swiss villager's day). Though all four roles are present in both the Buddhist and the Hindu villages, more transactions are in the individualist quadrant in the former, and in the hierarchist quadrant in the latter.

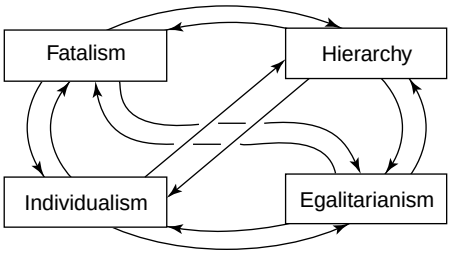

Figure 2 Transitions between solidarities and their associated transactional realms (individuals are able to move without causing change. It is when some transactions are shifted from one realm to another that we get change)

Furer-Haimendorf (1975) shows how the small agricultural surpluses of the cautious cultivators become the payloads of the adventurous trader's yaks as they set off on their journey into Tibet, and how the salt they bring back eventually finds its way to the cautious cultivators

Box 1 A Swiss villager's day

During the growing season an individual may on one day milk his cows, cut hay, thin saplings, maintain an avalanche control structure and wash dishes in a restaurant. The cows though privately owned are grazed on pasture owned by a specific set of long-established families. The hay is on his own private field; the saplings are part of a forest owned by another set of families; the avalanche control structure is on private land but maintained by agreement by the village; and the restaurant is owned by a multinational hotel chain.

This framework is fairly stable from season to season but the individual has a very different pattern of activity in the winter when the cows live in his private byre and much of the land is snow covered and barely used unless the valley includes a ski resort. If it does, then he has opportunities for work without leaving the valley. If not then he may leave to work elsewhere, thereby reducing the use of scarce resources at home. Thus in winter the human ecosystem centered on the valley is concurrently simpler and wider.

So our Swiss villager has a portfolio of transactions and management styles that fluctuates with the seasons and also with the longer-term dynamics (such as those that in altering the age-structure of the forests can eventually shift a whole category of transactions from one style to another).

- Like his Himalayan counterpart, he owns his hayfields and cows. These are private property; he can buy or sell them acting as an individualist, subscribing to the myth of nature benign.
- Coming from an old-established family, he is a member of a forest cooperative (Waldgenossenschaft) that gives him specific rights to cut trees and imposes a duty to maintain the forest. He is also a member of a pasture cooperative (Alpgenossenschaft) which annually decides the grazing season and the number of animals he may graze and requires him to contribute to the cowherd's upkeep. These are small-scale hierarchical institutions which have developed over the generations (in between the periods when the forests are privatized and their associated transactions transferred to the more exploitative individualist management style) in response to the limitations as well as the opportunities imposed by the natural environment: nature perverse/tolerant.
- As a voting member of the commune, he also has a duty to maintain resources that contribute to its survival such as the avalanche control structures that protect houses, fields and roads from damage. This tends to be an egalitarian involvement which recognizes that when it comes to these sorts of hazards, all the members of the community are in the same boat and that each should contribute his equal share: nature ephemeral.
- Lastly as a dishwasher in a multinationally owned restaurant, he is effectively a replaceable fatalist. His involvement is necessary if the enterprise is to continue but he has no interest in its future nor it in his and he can be paid off at any time (he will almost certainly lose his job at the end of the summer season).

who cannot produce this vital commodity. The distinctive strategy of each thus makes viable the other's, and we begin to see how it is that each village, in adjusting to its circumstances (which include the other villages), creates and takes its place in a social and cultural ecosystem, in which the marked divergence of the parts sustains the whole. Nor is this a fanciful analogy. As we show below, the adventurous traders' strategy matches that of the omnivorous and opportunistic r-selected species; the cautious cultivator's strategy matches that of the specialized and niche-dependent K-selected species (*see* r–K Strategies, Volume 2). The fatalists do for social systems what compost does for natural systems (provides a generalized resource for renewal). The egalitarians, through their small-scale communal fervor, are creating enclaves of low-level energy (what Marx, 1967, called primitive capital) in places where neither the r-selected nor the K-selected species can make any impression (Holling, 1986; Thompson *et al.*, 1990; Holling *et al.*, 1993).

So the ambitious hypothesis that is being sketched here is very different from the way people usually think about the interactions of social and natural systems. There is, on this view, no way of ever getting it right: of bringing the social into long-term harmony with the natural (which, of course, is the whole idea behind sustainable development). Instead, each is a four-fold and plurally responsive system, and their time-lagged interactions ensure that there can be no steady-state outcome. The whole system is in a perpetual unsteady state: changes at each level (the social and the natural) adapting to the other and changing it in the process, thereby setting in motion another set of changes. On and on. Nor are these changes predictable, as they would be if each level had only two possible states: hierarchies and markets, for instance, or, as is discussed below, their ecological analogues. Order without predictability (as opposed to transition from A to B, or oscillation between A and B, that the two-fold hypotheses give us) is the crucial idea behind this Himalayan story.

THEORIES OF CHANGE THAT MAKE CHANGE PERMANENT

Change, Cultural Theory argues, occurs because the four forms of social solidarity are not impervious to the real world. Just because people insist that the world is as their myth of nature tells them it is, it does not follow that the world really is so. If it is, that is fine, but if it is not, they have an uphill struggle. Surprise (the outcome of the ever widening discrepancy between the expected and the actual) is of central importance in dislodging people (and their transactions) from their form of social solidarity. And it is these various mismatches between what a way of life promises and what it delivers that continually tip people (and transactions) out of one form of social solidarity and into another. Of course, this hypothesis does require that the world, at times and in places, be each of these possible ways: otherwise we would all eventually end up surprised into the single true way. And it would help the surprises to continue indefinitely if the world itself kept changing.

Neither of these suggestions, some ecologists would argue, is particularly far-fetched. Holling (1986) and Holling *et al.* (1993) for instance, have elaborated the notion of requisite variety into a powerful critique of the conventional idea that the *climax community*, the ecosystem in which each specialized species has its stable and ordered niche, is the end of the organizational road. This critique exactly parallels Cultural Theory's dissatisfaction with the conventional hierarchies and markets account of things, in that it argues that there must be four, rather than just two destinations. Holling's critique is that the climax community eventually complexifies itself to the point where it undermines its own stability: an inevitable collapse, which has been proved mathematically by May (1982). This does not mean that an entire climax community (the Amazon rain forest, for instance) will suddenly disappear, but it does require any climax community to be patchy: to always include some localized areas in collapse as, for instance, happens when a mature tree crashes to the ground.

At this catastrophic moment, all the energy that is tied up in all the niches and interdependencies of the climax community is released. Holling, well aware of the parallel with Schumpeter's (1950) theory of economic maturity, collapse and renewal, refers to the transition from the climax community to compost, as *creative destruction*. Nor, he argues, is this the end of the road. With the whole place suddenly awash with capital (loose energy), the challenge is to fix it before it all disappears, by soil leaching, for instance. This, of course, is where the unspecialized and cooperative fence builders (microorganisms mostly) come into their own, gathering up the loose energy into small bundles that, as yet, have no connections with one another. But even this is not the end of the road, because the stage is now set for the appearance of yet different ecological players. These are the unspecialized but opportunistic, fast breeding and highly competitive r-selected species. These generalized exploiters (weeds, rodents and so on) are able to harness all the energy gradients that are now in place between all these unconnected bundles of energy. But these r-selected species, as they exploit and colonize this environment, inevitably begin to push it into a rather more patterned and interconnected state, thereby making it less conducive to their way of doing things and more suited to the sort of energy-conserving strategies that characterize the K-selected species: those specialized, slower breeding and often symbiotic, plants and creatures, which are the vanguard of the complex and increasingly ordered whole that constitutes the climax community.

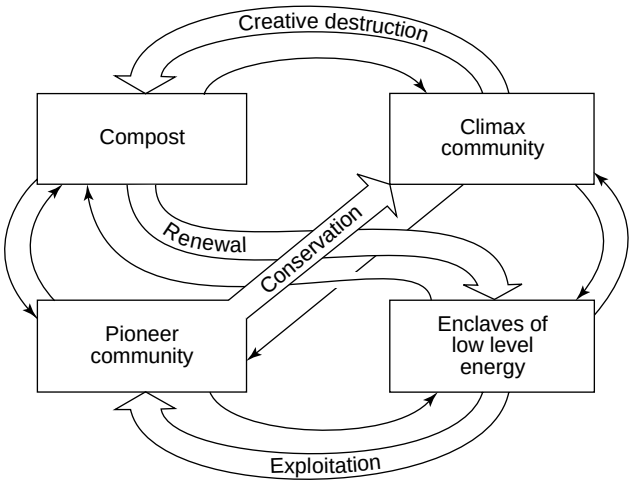

Figure 3 The complex critique of the conventional assumptions about natural systems (redrawn from Holling, 1986 to be homologous with Figures 1 and 2)

In other words, once you bump up the number of ecological strategies from two to four, there is no end to the road. Instead, there is a never ending set of transitions (twelve in all) that exactly parallels (in terms of dynamics, not substance) the social transitions of Cultural Theory. Holling goes on to argue that, while all twelve of these transitions do happen, there is a tendency for some to predominate at certain stages, thereby creating a fairly regular sequence of transitions: from specialized interdependence (the climax community) to unstructured fragmentation (compost) to unspecialized cooperation (energy fixing) to unspecialized competition (the pioneer community) to specialized interdependence (the climax community, again) and so on. He calls this sequence an *ecocycle*, and its description (which can be supplemented with descriptions of all the other cycles that are possible but, Holling believes, less pronounced) helps us to see the gulf (some might use the expression *paradigm shift*) that separates this model of change from the conventional one (Figure 3).

Is there, then, a socio-cultural equivalent of Holling s ecocycle? Yes, there is, and it can be most easily set out by reference to the theory of surprise: the theory that provides the bridge between the institutional and the natural: between us and the rest of nature.

ALWAYS LEARNING, NEVER GETTING IT RIGHT

A myth of nature provides its holder with a way of seeing the world and with a way of not seeing it. This means that, if the world happens not to be the way the myth holder is convinced it is, he or she will not notice this discrepancy straight away. Enlightenment, therefore, is always time lagged and, since it results in the enlightened one being tipped out of one quadrant of the Cultural Theory scheme and into one of the other three, it comes as something of a shock: a surprise. Surprise, in other words is always relative, which explains why, whenever something unexpected befalls us, there is always someone who saw it coming! The theory of surprise (Thompson and Tayler, 1986; Thompson *et al.*, 1990) is built on this relativistic, but far from unconstrained, foundation:

- an event is never surprising in itself;
- it is potentially surprising only in relation to a particular set of convictions about how the world is;
- it is actually surprising only if it is noticed by the holder of that particular set of convictions.

For instance, an individualist, whose myth assures him that an ecosystem is so robust that it will recover from any perturbation, will be surprised when it collapses catastrophically. Similarly, a hierarchist who is convinced that all ecosystems can be managed, with predictable results, will be surprised when this turns out to be untrue. Conversely, an egalitarian, who believes that nature is precarious, will be surprised when those who have disregarded precautions do not reap the expected disaster. And a fatalist will be surprised if bene ts, which he expects to be randomly distributed, continue to arrive.

Thus, surprises may be either pleasant or unpleasant, and a never ending sequence from one myth of nature to another may be proposed. Though all twelve transitions (see Figure 2) are possible, and we cannot say for sure what their order will be, we can spin a story to help us understand what is going on by privileging one particular sequence of possible changes so as to generate the socio-cultural analogue of Holling s ecocycle.

- Let us start with *nature benign*. In this state of the world, there is an excess of opportunity over existing investment, and this state, when interrogated by the myriad actions of individual agents, results in a positive-sum game in which a hidden hand keeps adding to the welfare of the totality. As long as the excess continues (that is, as long as there is no rim to the deep basin that contains the ball), and learning by experimentation continues, we have the state of affairs assumed by neoclassical economics.
- But, as they say in show business, Nothing recedes like success and eventually exploitative behavior causes the upper edge of the basin to turn downwards: *nature perverse/tolerant*. The excess, for some actors, has now vanished. Transaction costs rise steeply, innovation brings losses more often than pro ts, and markets fail. This is the transition from markets to hierarchies described by the new institutional economics (Williamson, 1975).
- Hierarchically sustained transactions, in their turn, transform the environment that ushered them in and

eventually the pocket of stability implodes: *nature capricious*. Both hierarchy and individualism (which has, of course, survived in the pocket) now start to lose their transactional grip and the world becomes a confusing, contradictory and unpredictable place: a place of which the fatalist's attitude; Why bother? makes perfect sense.

- This flatland, however, is less hostile to those small, egalitarian and self-disciplined groups that strive to bring their needs down within what they perceive to be Mother Nature's frugal limits, and these groups are therefore well placed to take advantage (though that is not quite the right word) of the recessive realities that are about to overwhelm the conventional institutional arrangements: the hierarchies and the markets.
- In this next stage, *nature ephemeral*, all increases in scale bring punitive diseconomies, and the economy (like the universe that contains it) winds down and down. The entropy principle (Georgescu-Roegen, 1971) and the dictum *small is beautiful* (Schumacher, 1973) make economic sense (*see* **Small is Beautiful**, Volume 5). Yet, no matter how lightly everyone treads on the Earth, the ball eventually rolls down the slope, coming to rest in some other basin (*nature benign*) and we are back where we began: in a positive sum world that rewards the bold and skilful and that brings increasing returns to those who are prepared to act expansively.

Throughout this process, changes in the environment result from the actions of those whose strategy happens to be best suited to making the most of the environment in which they find themselves. As more and more of these strategists act, these endogenous changes accumulate, and the environment passes over a threshold into a state better suited to one of the other strategies, *ad in nitum*. Though this complex model may start at the same place as the simple one and have the same dynamics, its paths are infinitely more surprising and unpredictable. In this inherently complex system, in which ecological and sociocultural components interact, each myth of nature captures some aspects of the world at some time. No one of them is ever right all the time and everywhere, and this means that each has its vital part to play. Clumsy institutions nurture that vitality; elegant ones destroy it.

Modeling Human Dimensions of Global Environmental Change

Marco A Janssen
Vrije Universiteit, Amsterdam, Netherlands

The history of humankind is a continuing record of interactions between people's efforts to improve their well being and the environment's ability to sustain these endeavors. Environmental constraints have led to innovations and social development, as well as social stagnation and human suffering. While the interactions throughout most of history were on a local scale, during the last decades awareness has grown so that the complexity and increasing scale of the interactions are demanding new forms of environmental management. New threats to mankind emerge, such as climate change, acid rain, ozone depletion, resource exhaustion, reduction of biodiversity, and limits to the availability of food and unpolluted fresh water. In fact, the globe is changing rapidly due to human activities, and humankind is, and will increasingly be, suffering from global environmental change.

One response from the scienti c community to understand the relations between human activities and the environment is the use of modeling, that is, constructing formal descriptions of natural and societal change and their mutual interactions. Although making accurate predictions for long term future developments is inherently impossible, models can help us to show the interdependence of various activities and consequences in time and space. In that way, models can be used to communicate information and insights from the scienti c community to policy makers and other stakeholders.

A number of fundamental issues in modeling the human dimensions of global environmental change are discussed. These dimensions relate to the interactions between humankind and the global ecosystem. How do human activities change our environment, how are humans affected by changes in our environment, and how does humankind respond to these changes? This contribution focuses on the behavior of humans in relation to their environment. Moreover, two fundamental related issues are discussed:

- *Given our limited knowledge of reality, we have to make all kinds of subjective assumptions about the functioning of human and natural systems in order to make decisions. How can models be of help for decision-making when subjectivity is unavoidable in developing models?*
- *On the macro-scale, phenomena are observed which are the result of actions of agents on lower levels such as of households, rms, organizations and nations. How can we explore future developments of these macro-scale phenomena?*

Although there is an increased use of modeling human dimensions of global environmental change, these issues are not well captured in current mainstream modeling practices. These issues are discussed in the context of developments in modeling human dimensions during the last 30 years and address promising developments for the future.

There are many kinds of models. A general classification is the distinction between formal mathematical models and non-formal models such as stories and cartoons. Sometimes people are role models of how one might live, such as Nelson Mandela or Claudia Schiffer. Only the formal models are dealt with here. The advantage of these formal models is that they are explicit and many of them are computer models that can be used to do repeated experiments.

Formal models are used in science very frequently, especially since the seminal work of Isaac Newton, more than 300 years ago. Formal models were mainly used to describe natural systems, such as calculating the trajectories of cannon balls or celestial bodies. Due to the success of these models, mathematical models were increasingly used in social science, especially in economics. However, human beings are not similar to cannon balls. Human beings can decide to obey traffic laws, but cannon balls cannot decide to obey the law of gravity.

The application of models from physics to social phenomena is problematic, but is still widely used. This article addresses new ways of modeling social phenomena by using multi-agent modeling to simulate interactions between agents, which are behavioral entities such as persons, households and firms. But first the field of modeling human dimensions of global environmental change is discussed.

Currently, models are widely used to describe the relations between human activities and the environment. Moreover, these models have often played a central role in setting environmental problems on the policy agenda, by exploring the consequences of alternative scenarios and by designing acceptable solutions for managing environmental problems. An example of an environmental problem for which the use of models is central is climate change. The possibility of human induced climate change is actually a policy problem that was put on the agenda after alarming model-based studies. Svante Arrhenius estimated at the end of the 19th century the consequences of a doubling of atmospheric carbon dioxide on the global mean temperature to be about 3 °C. Since the late 1950s, atmospheric carbon dioxide has been measured systematically, and currently the level is about 30% higher than pre-industrial levels. During the last 30 years, more detailed climate system models have been developed, and the results are compared with the increasing amount of (satellite) data. Still, these models are not able to describe observed climate accurately on a detailed spatial level. Besides increased efforts in modeling the climate systems, models of the human dimensions of climate change have been developed. These models were used to speculate on the possible consequences of climate change on economic growth, agricultural production and human health. Furthermore, models were developed to estimate the costs of mitigating so-called greenhouse gases. The impacts of climate change on various social and ecological factors are based on laboratory experiments, extrapolations from field studies, historical (regional) climate-change analogues and expert judgements. The increased insights into potential impacts of human induced climate change led to the current high position of the climate change issue on the policy agenda.

Policy decisions related to climate change are mainly determined by model outcomes. Many uncertainties, speculative assumptions and lack of information surround these outcomes. Thus, because the potential consequences of climate change as estimated by models are so severe, the precautionary principle is often advocated to reduce potential risks. Nevertheless, it is clear that the many uncertainties that surround the model outcomes have generated an intensive debate. Some scholars highlight the potential benefits of climate change on, for example, agricultural production, due to higher levels of atmospheric CO_2 and more suitable temperatures in Canada and Russia. Others argue that human induced climate change will not occur due to damping feedbacks of the biogeochemical cycles. Various scholars warn of positive feedbacks that may amplify climate change to catastrophic levels. The mainstream opinion on the size and impacts of climate change is represented by the reports of the Intergovernmental Panel on Climate Change (IPCC), an international scientific organization established in 1988 to assess scientific research on climate change. In 1995, the IPCC concluded that the balance of evidence suggests a discernible human influence on the climate. Although science is not a democratic process, the assessments of the IPCC try to synthesize a mainstream picture of the climate change issue which can be used in the international policy process to formulate policies to reduce greenhouse gas emissions. Such an authorized synthesized picture on the problem is desired by policy makers, since they have difficulty in handling the many uncertainties and complexities of the climate change problem. The model-based analysis of the IPCC suggests objective assessment. The idea that models can create objective predictions of the future is widespread among stakeholders who deal with global environmental change. Some stakeholders who doubt this objectivity do not want to use any model analysis at all. However, the traditional view that models guarantee or suggest objectivity is outdated. Model analyses, especially related to human dimensions, are highly influenced by subjective assumptions and interpretations. The challenge is to design ways to use models in such a way that they improve our understanding of reality. Improved mental models can improve decision-making. Therefore, the model-projections itself are not the most important element of model; rather it is the modeling process and the end use of models. This debate mirrors the discussion on world models during the early 1970s.

WORLD MODELS

Integrated models addressing the human dimensions of global environmental change elaborate a tradition that was founded in the early 1970s by the Club of Rome (*see* Club of Rome, Volume 4). Over the past 30 years many models have been built in the tradition of system dynamics, as well as other modeling techniques. In the early days the models of the Club of Rome were criticized as being based on too few empirical data, too high an aggregation level, and too many subjective assumptions. The criticism of the earlier models still holds for many of the current modeling activities.

The models of the Club of Rome were the so-called World models. Jay Forrester developed the World 2 model during the summer of 1970 based on his system dynamics approach. According to this approach, the world can be described through a conglomeration of interacting feedback loops. The World 2 model can be considered as a first sketch of a world model, without empirically based estimation of suggested causal relations.

A larger project, led by Dennis Meadows, resulted in the World 3 model, and the influential book *Limits to Growth* (Meadows *et al.*, 1972). The World 3 model contains the resource sectors, population, pollution, capital and agriculture on an aggregated global level. The standard run of the World models is one of growth followed by collapse

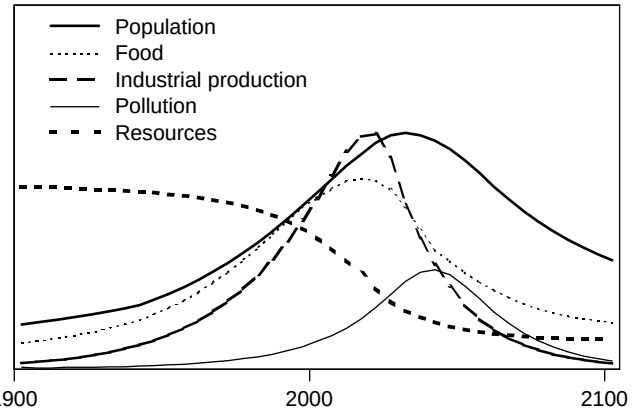

Figure 1 Standard Run of World 3. (Adapted from Meadows *et al.*, 1972)

(Figure 1). The collapse occurs because of non-renewable depletion. The industrial capital stock grows to a level that requires enormous input of resources, more and more capital must be used to obtain those resources, leading to less re-investment, and finally the collapse of the industrial base. Population decreases when the death rate is driven upward by a lack of food and health services. If the resource base is assumed to be much larger, collapse happens only a few years later due to food shortages and/or high pollution levels. Although it was recognized that there are various shortcomings in the models, Meadows and his colleagues argued that the model behavior was fundamental and general, and sufficiently developed to be of some use to decision-makers.

Managing Uncertainty, Complexity and Incomplete Information

Numerous scholars have criticized the World-model studies. Economist WD Nordhaus classified the World 2 study as misleading since it was not empirically tested enough and ignored mainstream economic insights. Other scholars concluded that due to the scarcity of relevant empirical information, relationships in the world models are subjective. Given the uncertainties, other sets of equally plausible assumptions can lead to a completely different picture. In fact, the outcomes of the models are largely the mental models of the model builders.

Some of the criticism was misplaced. The model outputs were interpreted as predictions, not merely as scenarios, i.e., what if' futures. So, when the predictions did not come true, scientists were blamed for inaccurate doomsday forecasts. Actually, the *Limits to Growth* scenarios had a profound effect on the public and government.

Scientific criticism on the World models of 30 years ago mainly concentrate on two topics. First, subjective assumptions had to be made about model relations and parameters due to incomplete knowledge or even ignorance. This was especially important for the linkages between subsystems. Examples were the effects of pollution on health, the interaction between demographic and economic dynamics, the role of technological innovations in resource availability, and the relations between material and energy inputs and economic output. Second, the complexity of the underlying subsystems and the linkages made it questionable whether a high aggregation level can lead to meaningful and relevant interpretations and results.

These problems of subjectivity and aggregated relations are still relevant for the current use of models. Although the use of models has increased, we still have no satisfactory solutions of how to manage incomplete information and insights, large uncertainties and different scales. This is illustrated here by the characteristics of the current generation of global models.

Integrated Assessment Models of Global Change

Global modeling re-emerged during the early 1990s as integrated assessment modeling, mainly because of the importance of the global climate change problem (Janssen, 1998). Integrated assessment models try to describe quantitatively as much as possible of the cause–effect relationships and the cross-linkages and interactions between the elements of the world system. Integrated assessment models are usually composed from meta-models of various subsystems. A meta-model is a simplified, condensed version of a more complicated and detailed model, which provides approximately the same behavior as the expert model from which it is extracted.

Integrated assessment models are one of the tools in the toolkit of integrated assessment. Other tools are policy exercises, dialogues between science and policy people, data analysis, scenario analysis and expert models. Integrated assessment is therefore a broader approach aimed at helping prioritize policy-making and research activities and giving insights into uncertainties and missing links of knowledge. It is used in a process whereby knowledge from a variety of scientific disciplines is combined, interpreted and communicated, with various stakeholders such as scientists, policy makers and non-government organizations involved.

The integrated models that are used describe the whole cause–effect chain from economics, energy production, emissions, land use changes, to changes in the biogeochemical cycles, the climate system, and impacts of climate change on human activities and the environment. There is no single approach to capturing the complexity of the system as a whole. In general, two types of approaches can be considered. The first approach, *process-oriented modeling*, is rooted in natural science and simulates the consequences of economic development on energy production, land use changes, biogeochemical cycles, climate system and impacts of climate change. The models are

often detailed at the spatial and temporal level. The other approach, *cost- bene t modeling*, is rooted in economics and maximizes discounted long-term welfare. Models using this second approach describe the physical consequences in less detail, but express the impacts of climate change and the efforts to reduce emissions in monetary units in order to derive an optimal response by balancing costs and benefits.

Both approaches are confronted with the same dilemmas as the World models of the early 1970s. Although much more empirical information is available, many components in models are surrounded by large uncertainties. Therefore, subjective assumptions have to be made. Also the complexity of scales remains an unsolved issue.

Besides these problems, most integrated assessment models have limited abilities to capture the broad human dimensions of climate change. The models are suitable for generating projections of economic output and the costs of climate change, but they are limited in many ways. Simple macro relations are assumed between economic activities and physical processes, but empirical insights are conflicting. Current (economic) models focus on utility of consumption as the driving force of human behavior, although it is questionable how this is related to the quality of life. There is limited insight into the physical dimension of satisfying human needs, but this understanding is needed before something plausible can be said about decoupling economic development and environmental pressure. Current integrated models include only the free market as an institution, although there are many other forms of economic organization and institutions.

One of the reasons for the limitations of the current generation of integrated models is the use of a rather mechanistic modeling paradigm, which is not able to include novelty, evolution and surprise. The role of modeling paradigms is now discussed in more detail.

MODELING PARADIGMS

A lot of controversies among modeling studies are caused by the difference in modeling approach that is adopted by the various scientists. Each modeling approach, or in a broader context, each modeling paradigm, involves its own set of theories, concepts, mathematical techniques, and accepted procedures for constructing and testing models. We can distinguish between deterministic and stochastic models, simulation and optimization models, reductionistic and integrated models, linear and non-linear models, one-agent and multi-agent models, and so on. Instead of discussing all kinds of possible paradigms, the difference between the reductionistic Newtonian approach and the complex adaptive systems approach is examined. This illustrates the transition in science that is currently occurring and explains fundamental differences on how to use models for assessing the future.

Mathematical modeling has long been influenced by physical science, which has developed a mechanistic, reversible, reductionistic and equilibrium-based explanation of the world. This proved to be very successful in calculating trajectories of moving objects (e.g., cannon balls) and predicting the positions of celestial bodies. The work of Isaac Newton, culminating in the *Principia Mathematica Philophiae Naturalis* in the late 17th century, was, and still is, very influential. The associated rational and mathematical way of describing the world around us was also applied in the social sciences, economics and biology. Despite the fact that later developments in the natural sciences seriously constrained the applicability of the mechanistic paradigm, its relative simplicity had a great appeal to scientists from various disciplines working with models. However, despite the widespread use of this approach, the mechanistic paradigm is increasingly criticized. The foundations of the mechanistic view: reversibility, reductionistic, equilibrium-based and controllable experiments, have faded away in the light of a number of new scientific insights.

First, the discovery of the Second Law of Thermodynamics brought down the notion of reversibility. The Second Law states that the entropy of a closed system is increasing. This means that heat flows from hot to cold, so that less useful energy remains. One of the consequences of the Second Law is the irreversibility of system behavior and the single direction of time. Changes within systems cannot reverse back just like that (irreversible). This is in contrast to many mechanistic models, in which time can easily be reversed to calculate previous conditions.

Second, the equilibrium view of species was brought down by Charles Darwin's book on the origin of species during the middle of the 19th century. The static concept of unchanging species was replaced by a dynamic concept of evolution by natural selection and adaptation of species, thereby fundamentally changing our view of nature. Natural systems are in continuous disequilibrium, being interdependent and constantly adapting to changing circumstances.

Third, the theories of quantum mechanics have confronted us with a fundamental uncertainty regarding knowledge about systems, especially on the level of atoms and particles. The uncertainty principle of Heisenberg is well known, stating that it is impossible to simultaneously measure the position in space and momentum (mass times velocity) of any particle. The statement by Laplace in the early 19th century that if every position of every atom was known, the future might be predicted exactly, became therefore a lost illusion. Moreover, the notion of fundamental uncertainty implied that fully controlled experiments are strictly speaking not possible.

Notwithstanding the fact that these developments in the natural sciences changed our perception of the world, (mathematical) models are still mainly based on

a mechanistic view of systems. For example, current mainstream economics is based on its success during the period after the Second World War, which was characterized by stable economic growth. Technology could seemingly handle any difficulty that came along. Affluence was seen as growing and permanent, and the standard of living, it was believed, would continue to improve for individuals and generations. The world economy was a place of simple equilibria and linear responses. Cost–benefit analysis, optimization and econometric models seemed to be quite appropriate.

Since the 1970s, various events have made us aware of the non-linearity of economic systems. The oil crisis ended unlimited economic growth, the Berlin wall collapsed in 1989, the Asian financial crisis at the end of the 1990s, the various crises on the stock markets, and so on. The economic system seems to be characterized by unstable states, non-linear responses and unpredictability. Still, mainstream economics uses its successful tools of the early days, probably because of their analytical power; certainly not because of their ability to explain reality. Increasing numbers of economists are trying new tools to explain the observed behavior of economic systems. This has led to the study of non-linear dynamics and evolutionary processes as emerging fields in economics although not always accepted by mainstream economists. This new type of economics studies the formation of patterns, evolution of economic systems, endogenous technologies, and so on. Furthermore, next to analytical tools, this new field of economics uses computers as a kind of laboratory to test hypotheses.

The emergence of new ways of studying the world around us has also emerged in other disciplines where studies are made of the origins of order, self-organization, emergence of structures, adaptation of agents in a changing environment, and many more new ideas. The general focus of this new modeling paradigm is to study how systems change and organize their components to adapt themselves to the problems posed by their surroundings. Examples of these systems are economies, ecosystems, immune and nervous systems, organisms and societies.

Although various scholars long ago discussed the importance of studying the evolution of systems, the rapid developments of the computer have provided scientists with a new tool in recent decades, which can be used to investigate evolution, self-organization, interactions between agents and emergence of structures on a macro scale by simple local rules. These systems can be grouped under the common name complex adaptive systems. They are studied by a number of new computation-based modeling tools, including genetic algorithms, cellular automata, neural networks, and artificial life forms.

The characteristics of these new types of tools are illustrated using one of these tools: genetic algorithms. *Genetic algorithms* have been developed to simulate the process of natural selection by considering a population of agents producing offspring who are similar, but not identical, to their parents. This process depends on three genetic operators: selection, crossover, and mutation. *Selection* means that the genetic algorithm selects n copies of the strings (genetic code) in the population by a random process that favors the most fit. Subsequently, these copies are probabilistically paired in a mating process whereby each pair produces two offspring by means of crossover and mutation. *Crossover* means that two offspring are created with a certain probability that the genetic information is crossed over; otherwise, the offspring are identical to the parents. In the case of crossover, the parent strings of genetic information are split randomly and are swapped to shape two new strings. Each element of the genetic information has a small probability of being altered. This *mutation* is independent of what happens with the other genetic information. Due to their adaptive characteristics, genetic algorithms are powerful tools for improving and finding good solutions even in complex changing environments. Moreover, genetic algorithms are based on irreversible changes, stochastic processes and evolution (*see* Resilience, Volume 2).

Genetic algorithms are one of the computational tools used for developing models to study complex adaptive systems, which emerged as a new field in science. Since the late 1980s, the Santa Fe Institute has provided a prime focus for exploring and deepening the insights from complex adaptive system studies and provided new opportunities for transdisciplinary studies (Waldrop, 1992). It is expected that the study of complex adaptive systems will become an important field in transdisciplinary environmental science. The Resilience Alliance is one of the first international communities to study environmental science from this new perspective. An overview of their work is given in Gunderson and Holling (2001).

Validity of Models

An important difference between the two modeling paradigms is how to use models, and how to validate models. From the viewpoint of mechanistic explanations of reality models are valid when predictions generated by the model are not rejected. An example of this Popperian type of validation is the development of an econometric model. The timeseries of data is split into two. One part is used to estimate the model and to generate predictions, and the second part to test the predictions of the constructed model. This empirical validation leads to problems according to the complex adaptive systems paradigm, which focuses on evolving structures and is often based on qualitative insights. Since small differences in initial values can lead to large output differences, models of complex adaptive systems are not suitable to generate predictions. In fact, this problem goes back to the classical three-body problem (e.g., the system involving Earth–Moon–Sun), which

has been studied extensively with a variety of methods beginning with Newton. Despite the large number of studies, no complete analytic solution in closed form has been found. Furthermore, for some initial conditions this system is found to produce chaotic unpredictable behavior. This example shows that when interactions among agents are taken into account, the Newtonian approach does not work. Therefore, validation in this line of modeling is based on expert judgements and relations with theoretical insights. This type of validation can be called conceptual validation. In fact, validation is not a test, but a subjective process.

The difference between opinions on how to measure the quality of models leads also to differences in how to use models. According to the Newtonian modeling paradigm, a model that is tested empirically and is validated can be used to make accurate and objective predictions. However, according to the complex adaptive system perspective, models can only be used to study qualitative structures, and should be used interactively to be able to exchange insights and stimulate discussion on uncertainties. In the physical sciences, one no longer refers to model validation, but rather to model performance, which is provided by statistical measures such as the root-mean-square differences between model predictions and observed values.

If one wants to describe the orbits of planets, a mechanistic model is a perfect tool. Mechanistic models are even suitable tools when one wants to send men to the Moon. But in situations of many uncertainties and surprises, such tools will not work. In the case of living beings, mechanistic approaches are of limited explanatory power. In the rest of this article modeling human dimensions of global environmental change from the perspective of complex adaptive systems is discussed. From this new perspective, we look at how to design and use models for exploring the future. But first, one of the main seeds of uncertainty and subjective assumptions is discussed: stability characteristics of systems.

MYTHS OF SYSTEMS

Different perceptions of reality can be visualized by different myths of stability, that is the perception of how systems function. According to the equilibrium myth, systems are in equilibrium. External effects can push the system briefly out of equilibrium, but it automatically returns back to the previous equilibrium situation. This myth corresponds very well with the Newtonian-modeling paradigm. Not only the natural system is considered to be in a natural equilibrium, but also the economic system of supply and demand is in equilibrium due to control of the invisible hand. This metaphor from economist Adam Smith, proposed at the end of the 18th century, was a powerful explanation of micro-behavior in order to describe an elegant mechanical description of the macro-level of economic behavior.

The myth of stability can be represented graphically as a ball at the bottom of a valley (Figure 2a). Perturbations only temporarily knock the ball away from the bottom of the valley. An implicit assumption of this myth is that systems have the capacity to damp all kind of disturbances.

An alternative myth is the obverse, namely the myth of instability. Systems are assumed to be very sensitive to disturbances. Every disturbance can lead to a catastrophe. Applied to environmental issues, the myth of instability explains why some people argue that human activities should not be allowed to disturb the natural system. Any degree of pollution or degradation of extraction can lead to a collapse of the system. This myth can be visualized by a ball on a peak (Figure 2b). Any perturbation can lead the ball to roll down the slope.

A third myth is in between the myths of stability and instability, namely a system is assumed to be stable within limits. When the system is managed well, the system can absorb small perturbations. This myth can be visualized as a ball in the valley between two peaks (Figure 2c).

A more advanced framework is to consider multiple stable states. As depicted in Figure 2(d), this myth can be represented as a number of peaks and valleys. The ball is resting in a valley and is able to absorb a certain degree of disturbance. However, an extreme disturbance can push the ball over a peak such that it will rest in another valley, an alternative equilibrium state. Examples of these multiple states are lakes, which can flip from an oligotrophic to a eutrophic state due to inputs of phosphates, and rangelands that flip from a productive cattle-grazing system into a less productive rangeland dominated by woody vegetation, triggered by variability in rainfall.

A myth of systems that is more advanced, and lies in line with the complex adaptive system modeling paradigm, is the myth of resilience.

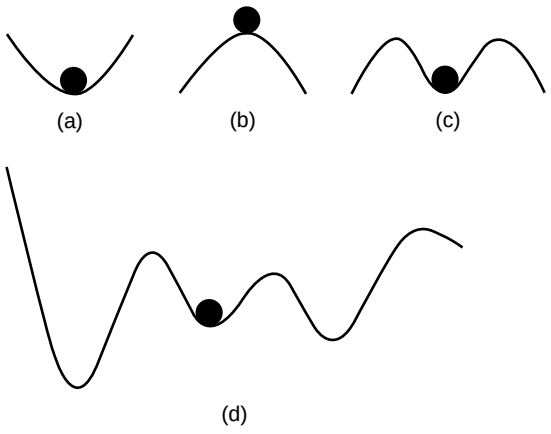

Figure 2 Myths of nature: (a) nature is stable; (b) nature is unstable; (c) nature is stable within limits; (d) nature has different stability domains

Myth of Resilience

The myth of resilience does not only consider the balls moving up and down the peaks and valleys, but also considers possible movements of the peaks and valleys themselves. In this evolutionary picture stability domains can shrink, and disturbances that previously could be absorbed no longer can be. This view has important implications for managing systems. From the perspective of the previous myth of systems, systems could be known perfectly. Surprises may lead to changes of management, because the balls moved in another valley, but in principle, management was simply a matter of controlling the system. From the perspective of an evolving landscape, one has to manage a system in the face of fundamental uncertainties over the functioning of the system. One continually observes the system in order to respond adequately. Moreover, small human-induced perturbations are supported in order to learn from the system. This type of management is called *adaptive management* (*see* Adaptive Environmental Management, Volume 4).

Holling (1986) has proposed a framework for resilience to explain the transitions in behavior of the system. He distinguishes four basic functions common to all complex systems, and a spiraling evolutionary path through them (Figure 3). This evolutionary cycle can be used to explain transitions in social systems, as well as in ecosystems. The central idea is that the four-phase adaptive cycle emphasizes a loop from conservation to two phases of destruction and reorganization in which innovation and chance assume dominant roles. The reorganization phase occurs when a rare and unexpected intervention or event shapes a new future. In this state, the system is most likely to be transformed by innovation, and agents have the greatest potential to influence the future of the system. When the agents do not react properly to changes in the system, it can flip into a new kind of system.

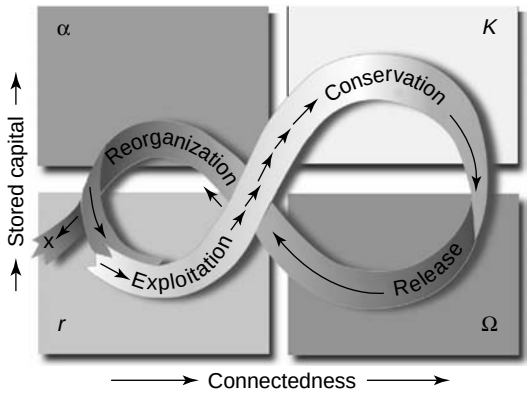

Figure 3 The dynamics of a system as it is dominated by each of four processes: rapid growth (r), conservation (K), release (•), and reorganization (α). The arrows indicate the speed of the cycle. The short, closely spaced arrows indicate a slow change, while the long arrows indicate rapid change. The cycle reflects systemic change in the amount of accumulated capital (nutrients, resources) stored by the dominant structuring process in each phase, and the degree of connectedness within the system. The exit from the cycle at the left of the figure indicates the time at which a systemic reorganization into a less or more productive and organized system is most likely to occur. (Adapted from Gunderson and Holling, 2001)

As mentioned before, the landscape is changing. This has much to do with different speeds of change in the various scales of systems. For example, due to phosphorus accumulation in sediments of lakes, recycling of phosphorus from these sediments can lead to surprises. The slow variable, the sediment, can reduce the capability of the lake to absorb an external disturbance. The equilibrium levels of concentration of phosphorus in the water, the fast variable, can therefore change due to changes in the slow variable (Gunderson and Holling, 2001).

According to the myth of resilience, problems could be caused by local human influences that slowly accumulate to trigger sudden abrupt changes that may affect the vitality of societies. There are counteractive forces that give ecological systems the resilience and adaptability to deal with considerable change, and that provide people with the capability to innovate and create. However, nature, people, and economies are suddenly now coevolved on a planetary scale, each affecting the others in such novel ways, and on such a large scale, that large surprises may overwhelm the adaptive and innovative capabilities of people. One challenge of sustainable development is, therefore, how to stimulate coevolution of human activities and environmental change.

Different Perspectives on the Problem of Climate Change

The discussion of myths shows various possible subjective interpretations of reality. The importance of different perspectives for modeling the human dimensions of global environmental change is now illustrated. There are various concepts designed to classify different worldviews. Like the case of modeling paradigms, there is no true classification of worldviews. A contribution, which gives a general description of perspectives on natural and human systems and social relations, has been made by Michael Thompson and his colleagues in their cultural theory (Thompson *et al.*, 1990). This theory has been used to classify different types of institutional designs in relation to global environmental change. The cultural theory has been an inspiration for implementing worldviews in formal models, because it includes perspectives on human as well as natural systems, it claims generality, and its explanation of perspectives' rationalities is deterministic. The cultural theory combines anthropological insights with ecological insights, resulting in different cultural types.

The three main worldviews in the Cultural Theory are the following types:

1. Individualists assume that nature provides an abundance of resources, and remains stable under human interventions. A responsive management style is advocated.
2. Egalitarians assume that nature is highly unstable, and a small human intervention may lead to complete collapse. A preventive management style is preferred.
3. Hierarchists assume that nature is stable in most circumstances but can collapse if it crosses the limits of its capacity. Therefore, control is advocated as a management style.

As discussed earlier, human induced climate change is a topic surrounded with many uncertainties. It is, therefore, an excellent example to illustrate how worldviews can be quantified to simulate alternative futures based on different perceptions of reality. Such an analysis has been made by Janssen and de Vries (1998) who developed a simple integrated ecological economic model for which they implemented three versions based on alternative assumptions on climate sensitivity, technological change, mitigation costs, and damage costs due to climate change. Egalitarians, for example, assume high climate sensitivity, high damage costs, low technological development, and low mitigation costs. For management styles, they assume different strategies for investments and reductions of emissions of carbon dioxide. By contrast, the individualist, for example, assumes a strategy that maximizes economic growth, and emissions are reduced only if a certain threshold of economic damage is exceeded. The hierarchist tries to balance economic growth and climate change by assuming the IPCC estimate of climate sensitivity.

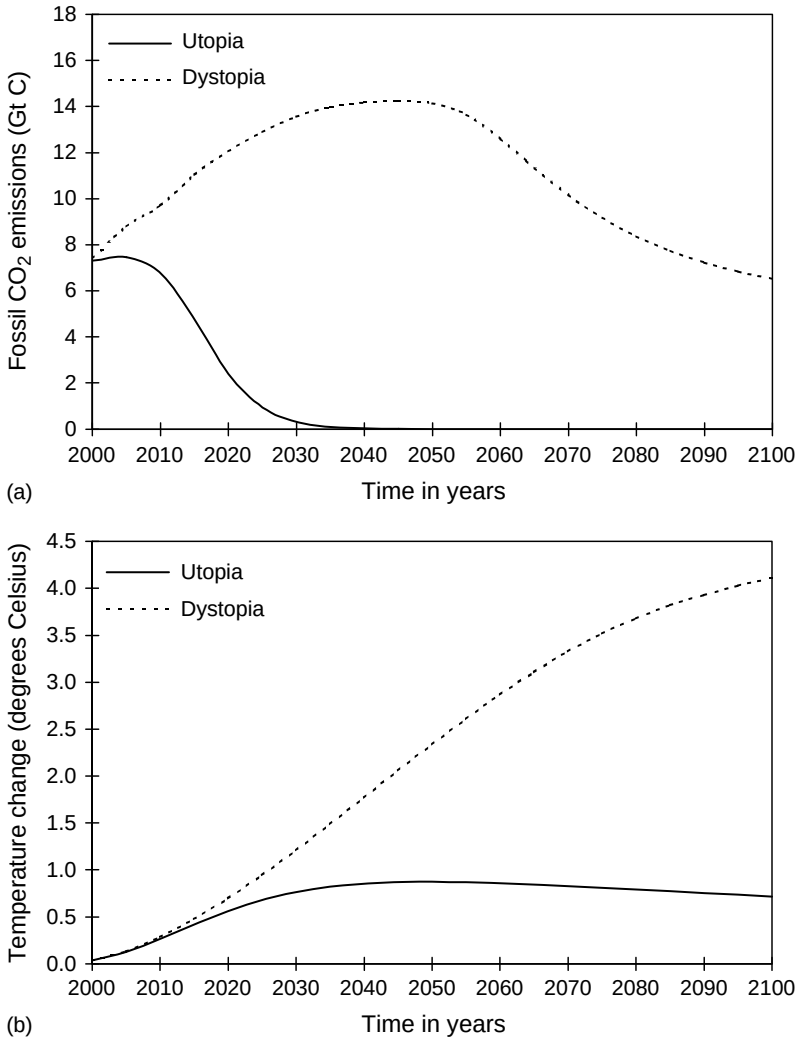

Figure 4 Expected carbon dioxide emissions (a) and temperature increase according to the egalitarian utopia and a possible dystopia (b) (individualistic management style in an unstable global system)

Suppose that all of the agents in a model world share one of the three extreme worldviews. If agents are assumed to have perfect knowledge of their world, their utopia can be simulated. If their worldview is incorrect and they still apply their preferred management style, their dystopia can be simulated. An example is presented in Figure 4. In the egalitarian utopia, emissions of carbon dioxide will be reduced to zero within a few decades, leading to a modest temperature change. However, if the individualistic worldview manages a world that actually operates according to the egalitarian worldview, emissions increase until climate change causes such an economic disaster that emissions are reduced by the collapse of the economy.

By introducing a population of agents with heterogeneous worldviews, a complex adaptive system is produced. It is assumed that the better an agent worldview explains the world's observed behavior, the greater is the chance that an agent will not change its worldview. On aggregate, there is a trend towards changing to the worldview that explains the observations in the most likely way. Suppose that reality is one of the three possible worlds, and an agent obtains information over time that causes him to change (or not) his perspective on the climate change problem. Three sets of projections are derived in which agents adapt to climate change (Figure 5). Prior to the year 2040, the observed climate change does not lead to domination of one of the worldviews. After 2040, the climate signal becomes clear enough that one of the worldviews begins to dominate. In the event of the world functioning according to the egalitarian worldview, the emissions growth stabilizes on average in the coming decades and decreases to a level below half the present amount of emissions. However, this reduction cannot avoid a global mean temperature increase of about 2.5 °C in the 21st century.

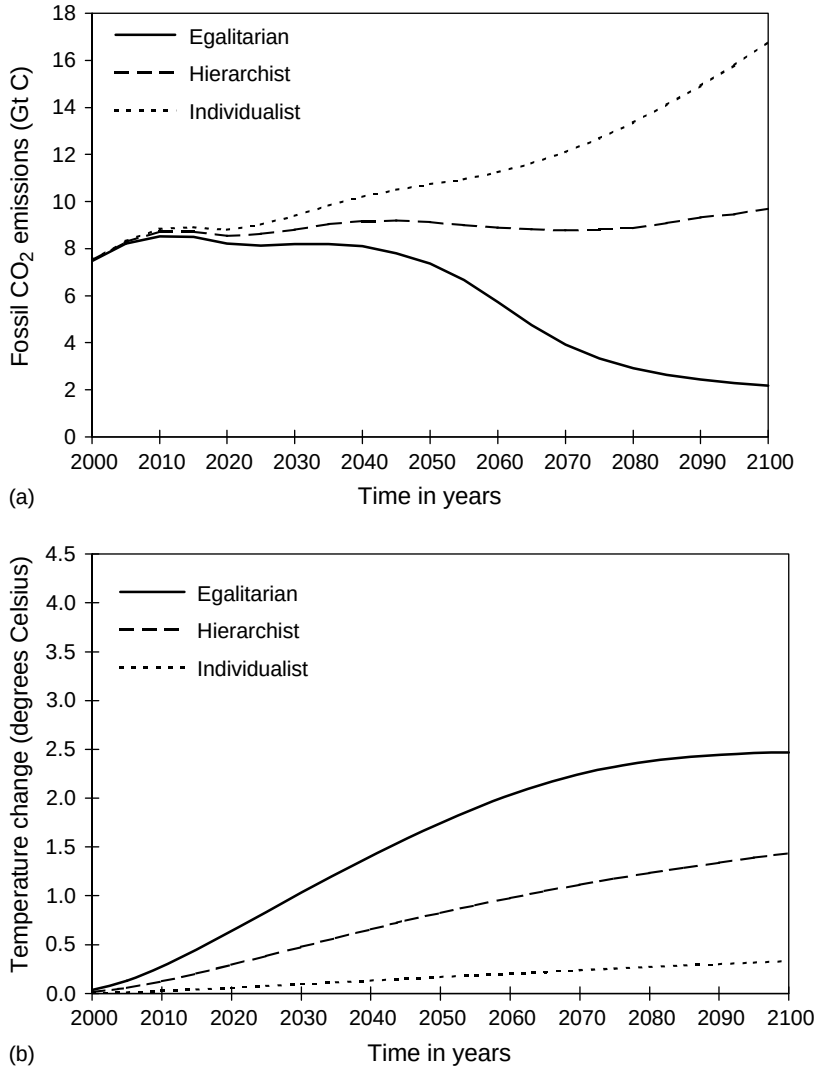

Figure 5 (a) Expected carbon dioxide emissions and (b) temperature increase according to different views on the functioning of the global system, and where the worldviews of agents change in time

The explicit inclusion of subjective perceptions of reality has led to a rich variety of possible futures. This will not simplify decision-making, but can improve decision-making since a large set of plausible scenarios is presented. This type of modeling is currently applied in different areas of global and regional environmental change. Each system in which it is not certain that it will remain stable under all kinds of disturbances, can in principle be studied by explicitly assuming different perceptions of reality. It is the expected that this type of modeling will be especially interesting for simulation of institutional dynamics.

MACRO-LEVEL DYNAMICS

Although there are often uncertainties about the relations, global models simulate macro-level dynamics. Here, we focus on the most important macro-level drivers of global environmental change, which are population size, economic development and technological change. In the early 1970s, Paul Ehrlich and John Holden described the environmental impact of society by the well-known IPAT equation: $I = P \times A \times T$. Here environmental impact equals the product of population size, the degree of affluence per person and the environmental impact from the technology used to produce one unit of affluence.

The coming sections discuss three factors that are closely related to the IPAT equation: population growth, material and energy consumption of economies, and technology development. For each factor, empirical information on the macro-scale provides information on possible developments in the long term. However, extrapolating historically derived macro-level relations involves subjective assumptions. Therefore, it is important to explore the consequences of these subjective aggregated relations and to improve understanding of the empirically derived macro-level information.

Demographics and Human Health

Population growth is one of the main causes of global environmental change. The continuing population growth can be explained by changes in demographics and health. The so-called demographic and health transition describes how populations can go through typical demographic and health stages when they change from living in pre-industrial conditions to having a mortality pattern that is found in the post-modern societies (*see* Demographic transition, Volume 5).

The shapes of the demographic transition curves are well known, but are in fact a hypothesis based on cross-national and longitudinal studies. In developed countries the demographic transition has reached the final stage. But how will this development of fertility and mortality figures continue in the future? Will the developing countries follow the same transition, and at what rate? Most population projections are based on the assumption that all countries will go through the demographic transition leading to a leveling off of population growth during the 21st century. Observed transitions in demographics are the result of changes in individual behavior, technology and norms, improvement of health care, use of contraceptives, age of marriage, literacy, position of woman, regulation of abortion, etc. It is expected that due to all these variables involved, the demographic transition will not occur everywhere to the same degree and at the same speed. Therefore, subjective assumptions have to be made in order to develop projections for the coming centuries.

Assumptions about the health transition in various regions of the world are even more difficult since various diseases are related to global environmental change (skin cancer due to stratospheric ozone depletion), behavior (lung cancer from smoking), emerging new diseases (acquired immune deficiency syndrome – AIDS) and even some re-emerging old diseases due to the development of new resistances (malaria). It is therefore difficult and subjective to project health conditions of our descendants.

The Material and Energy Consumption of Economies

An economic system can be viewed as a living system, consuming material and energy inputs, processing them into usable forms, and eliminating the wastes. The metabolism of economies has changed significantly during the last two centuries. A world economy has emerged that produces agricultural, and industrial products and services in large volumes, and transports them all over the globe. Agricultural production has increased due to more and more intensive use of land. Productivity has improved due to biological innovations in the form of new crops, new agricultural practices, mechanization, and increasing synthetic inputs. The same holds true for industrial production, which is increased due to the increasing consumption of energy and materials. Currently, the service sector is becoming increasingly important, stimulated by increased personal mobility and more individualistic lifestyles.

These economic developments have led to an increase of material and energy use in absolute figures, but also in *per capita* figures, and have led to all kinds of disturbances of biogeochemical cycles. These disturbances have led to environmental change on various scales.

The debate whether the environment is able to sustain economic development goes back to Thomas Malthus at the end of the 18th century, who argued that food production could not be increased quickly enough to keep pace with the growing population. But due to a faster increase of agricultural productivity than expected, a decrease in birth rates, and the growing import of food, Malthus' homeland

(Great Britain) did not collapse. Since the early 1970s, stimulated by the *Limits to Growth* report of the Club of Rome, the debate on economic growth and the environment has emerged again.

In the last 30 years, there have been attempts to improve the physical reality of economic models by including mass balance conditions, and laws from thermodynamics. However, there is still no clear theory on the relation between economic development and the environment. In the 1990s a lot of empirically based studies were published on the relation of environmental pressure of an economic system and the average income. This so-called Environmental Kuznets curve (see, for example, de Bruyn, 2000) (Figure 6) consists of three phases:

1. initially income growth parallels progressively increasing environmental pressure;
2. next, further income growth leads to increasing environmental pressure until it reaches a maximum;
3. further income growth leads to a reduction of environmental pressure.

An explanation for this pattern is that at higher income levels, individuals will attach more value to environmental quality; this means more income spent on less damaging consumption, as well as more democratic support for stringent environmental policies. An important implication of the environmental Kuznets curve is that growth by itself would be able to solve environmental problems. However, the empirical support for this hypothesis is weak and mainly based on cross-sectional analysis. It is not clear whether the curve differ for different types of environmental pressures, what is the influence of policy measures and technological change, and whether observed trends in the past will continue in the future. Some studies suggest that delinking of environmental pressure and economic output has only been a temporary phenomenon caused by efficiency and technology improvements after the oil crises of the 1970s (de Bruyn, 2000). The cheap energy prices of the 1990s led to a relinking of environmental pressure and economic output. Despite the many uncertainties, relationships between physical and financial dimensions of economic systems like the environmental Kuznets curve are used to explore future material and energy consumption.

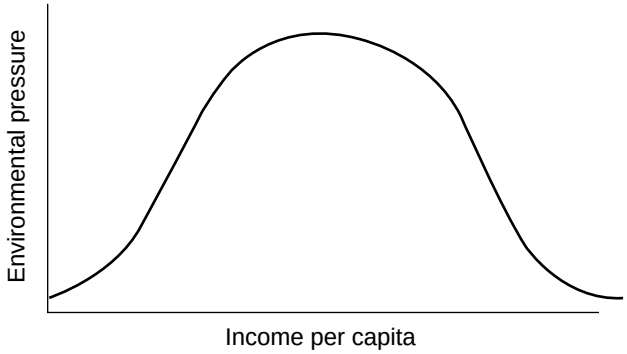

Figure 6 Environmental Kuznets curve

Technological Change

Technology development is the source and remedy of environmental change. This is called the paradox of technology and the environment. It is the source, because it creates the ability of societies to mobilize more materials and energy, and because it creates new materials and substances with direct environmental impacts. On the other hand, technology can also be the remedy because it increases productivity and efficiency of economic activities and invents specific technologies to prevent pollution.

It is therefore important to understand the dynamics of technological change. Arnulf Grubler (1998), in his book on technology and global change, discusses general mechanisms on the diffusion of technology. The question is how a new technology is adopted at a large social and spatial scale. This can be visualized by the stylized technology life cycle (Figure 7a). In the beginning, a new technology is imperfect, and various possible designs are

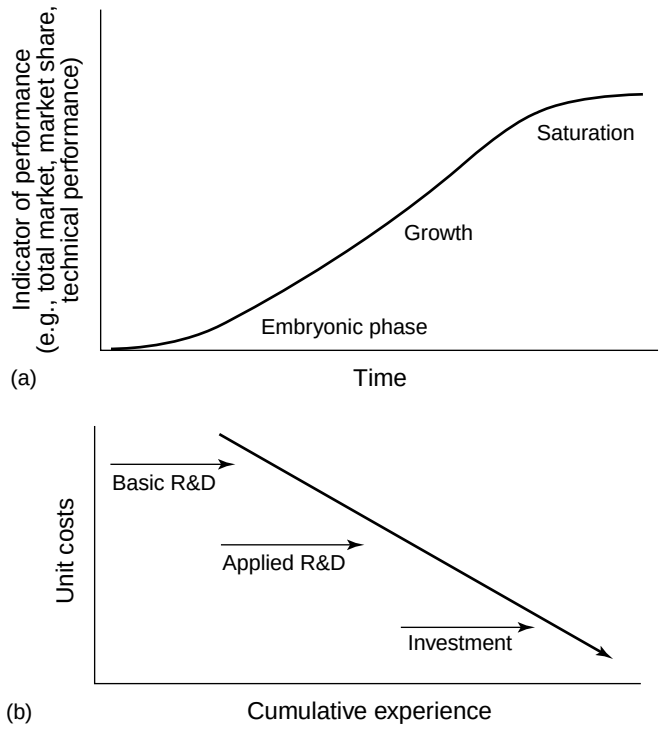

Figure 7 (a) a stylized technology life cycle; (b) a stylized learning curve, where axes scales are logarithmic. In the beginning costs decrease due to basic R&D. When the potential of the technology is demonstrated, applied R&D investments reduce the costs further until a level is reached for which costs are competitive. (Adapted from Grübler, 1998)

explored. The market effect is small, but the increase that occurs during the growth phase is characterized by increasing standardization and falling costs. Finally, the growth rate slows down as the market becomes saturated. In this phase the market is in the hands of a few suppliers.

Technology life cycle is related to the developments of costs. There is a lot of empirical evidence that the decrease of a technology investment cost is related to the accumulated investments in the particular technology. This learning-by-doing can be formulated by the technology learning curve (Figure 7b). The costs (on a logarithmic scale) decrease linearly with an increase in cumulative experience (on a logarithmic scale). The main uncertainty of technology in the early phase of development is the slope at which the costs decrease.

In mainstream economic models, technology is often included as an exogenous variable. Such an assumption leads to wait-and-see policies because investments are delayed until clean technology has become available at suitable cost levels. Such a policy differs from insights derived from the learning curve, which suggest stimulation of investments in clean technology allowing costs to decrease.

Insights into technology dynamics show stylized facts derived from empirical studies. This provides tools for modeling technology development. The main question is how does an individual technology penetrate the market, and how can governmental policy stimulate the diffusion of green technology? Many decisions of individuals influence this evolution. Therefore, we need to have more insights into models of human behavior.

UNDERSTANDING THE EMERGENCE OF STYLIZED FACTS

The observed stylized facts, the observed macro relations, are the result of decisions of many agents. They are emergent properties of a complex adaptive system. To improve our understanding of these observed stylized facts, we should develop tools to understand them. One way is to use models that are able to simulate these emergent properties from the bottom up. Like the cartoon (Figure 8), understanding of macro level phenomena can only be derived by studying the behavior of micro level agents. In the case of a school of fish, multi-agent studies have shown that flocking behaviour can be simulated by using three simple rules for each agent:

- separation: steer to avoid crowding local flockmates;
- alignment: steer towards the average heading of local flockmates;
- cohesion: steer to move toward the average position of local flockmates.

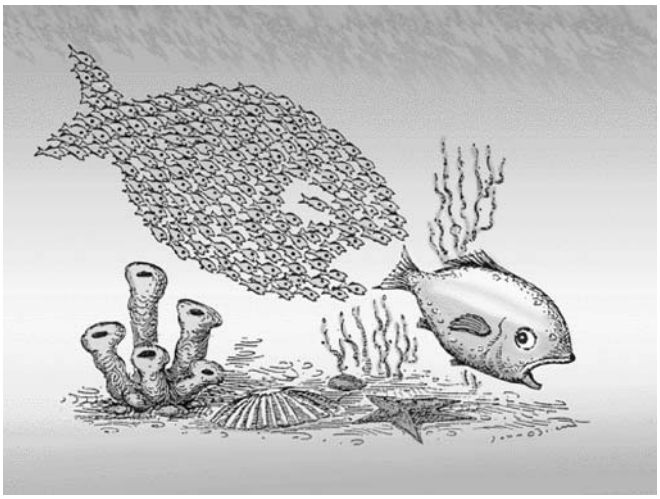

Figure 8 Macro level phenomena emerge from behavior of agents on the micro level

Behavior of human agents is much more difficult to capture by simple rules. Two types of human behavior can be distinguished: individual behavior, and behavior of groups and institutions.

Individual Behavior

Since theory development in social science is rather fragmented, various models of human behavior exist. In fact, different disciplines study only particular aspects of human behavior. One central element, or better, one stylized problem, is found in most models of individual behavior. Humans are assumed to maximize their well being given budget constraints. These budget constraints mainly relate to income and time. Within economics and psychology, different variations exist on this stylized problem. In the formal approach of conventional economic theory, this means that the rational actor, the *Homo economicus*, maximizes its own well being. This *Homo economicus* is assumed to have perfect knowledge of the system in order to find the global optimum. In the case of uncertainties, the probability distributions are perfectly known. These assumptions make it possible to formalize human behavior in an unequivocal way. A drawback is the existence of much empirical evidence that real humans do not behave in this way. For example, experiments show that humans discount the near future at a higher rate than the distant future, experience well-being with relative changes instead of absolute levels, and are about twice as averse to taking losses as to enjoying an equal level of gains (e.g., Thaler, 1992).

Some economists, like Nobel Laureate Herbert Simon, argue that humans are rationality bounded. First, no person can ever assemble all the information required for an optimal decision. Second, even if one could, decisions are usually so complex that no simple algorithm exists

for evaluating all possible options. Third, a person's own decisions depend on the decisions of other persons. Simon argues therefore that humans satisfice instead of maximize their well being. A consequence of relaxing the assumption of maximizing behavior is the large set of possible rules that describe behavior. The formalization is not unequivocal anymore. Thanks to the development of new simulation techniques such as cellular automata, genetic algorithms and neural networks, and the widespread availability of personal computers, social scientists are exploring new ways of modeling human behavior (e.g., Gilbert and Troitzsch, 1999).

Psychologists and other social scientists include different indicators than are usually used in economics. Psychologists focus on satisfaction of various types of needs such as understanding, freedom, identity and leisure. Furthermore, all humans are different. They differ in their abilities, mental models, preferences and opportunities. In contrast with *Homo Economicus*, decisions depend on social interactions, as well as on individual considerations. In fact, humans are assumed to perform different cognitive decision processes in different situations.

The mental models of humans are important elements in cognitive processing. Differences in perceptions of reality can result in different behavioral patterns. Although humans can learn, they will never have the perfect knowledge that is needed to maximize well being as performed by *Homo Economicus*. This picture of human behavior is in line with the complex adaptive system-modeling paradigm. Since humans cannot perfectly control their own situation, they design institutions to regulate human interactions, as well as interactions between society and the environment.

Institutions and Collective Actions

Institutions contain formal constraints (rules, laws, constitutions), informal constraints (norms of behavior), and their enforcement characteristics. They shape human interactions and the way societies evolve through time, and can also be important to regulate human activities in relation to ecological conditions. A stylized problem that is generally used to study institutions is the so-called *commons dilemma*, widely discussed as a result of the well-known analysis of Garrett Hardin on the *Tragedy of the Commons* (*see* Commons, Tragedy of the, Volume 5). According to this analysis, the commons tend to be overharvested since each agent harvests to the point where private costs equal the benefits, whereas harvesting imposes additional social costs on the rest of the community. However, historical analyses of common resource properties have found many examples where the tragedy did not happen (Ostrom *et al.*, 1999). Communities often had ways of self-organizing to prevent overexploitation of the commons, also known as closed commons. Success of self-organization depends heavily on the characteristics of property-right systems. The tragedy of the commons is an example of open access, where everybody can harvest without individual punishment. However, other types of property regimes to regulate common resources are related to group, individual and governmental property.

The success of self-organization of effective institutions to control common resources depends on property regimes, as well as evolution of norms and design of rules. Again, this is an excellent example of complex adaptive systems.

DIFFERENT WAYS OF USING MODELS

It should be clear by now that models are not of use to accurately predict future developments of human dimensions of global environmental change. Although models are often used for this purpose, there are more suitable purposes for which they are of importance. In fact, they can be used to overcome the problems raised during the analysis of the current generation of integrated assessment models. Instead of focusing on a single model used for prediction, a combination of different types of models should be used to explore hypotheses and uncertainties. Models can be used in different ways. Here, three different goals of use are distinguished: to understand observed stylized facts, to improve decision-making of complex problems due to interactive use of models, and to explore possible futures by scenario developments.

Understanding Stylized Facts

In the descriptions of the various sectors a number of stylized facts were identified, such as the demographic and health transition, diffusion of technology, and environmental Kuznets curves. These macro-level observations are the result of behavior of agents at smaller scales. To understand stylized facts, and to explore possible changes in macro-level relations, we need to study the behavior of the underlying components. Can we explain the diffusion of technology by using simple rules for agents? Under which assumptions can an environmental Kuznets curve be simulated by micro-level decisions of economic agents?

This type of question relates to current work in evolutionary economics. Various studies analyze what are the important characteristics of firms and technology development to explain structures emerging in specific markets. Examples are the size distribution of firms, and the large number of firms during the beginning of a new market. Such analyses are also frequently performed by various other disciplines, and are assumed to be valuable to understand the underlying dynamics of the observed stylized facts.

Interactive Use of Models

Models are not prediction machines, and should not be used in this way. Moreover, for policy analysis, models

should be made available in such a way that they can be used in an interactive fashion. The recent developments in graphical user interfaces, PC availability and Internet, should make it possible to use simple transparent models by a large community of stakeholders. Models can be used in this way as learning tools. Using models in this way is exactly what we can learn from the work of Dorner (1996).

Dietrich Dorner and his colleagues study decision-making in complex situations. Their research design is to develop micro-worlds, which are computer simulation models of a management problem, and to ask real persons to manage the system. These management problems vary from a simple climate-control system to regulation of a virtual society. Because the participants in the game have an incomplete picture of reality, their attempts to manage the system can lead to catastrophes. Dorner concludes that managing complex situations requires experience, and this experience can be built up by playing management games, like training pilots in flight-simulators.

Scenario Development and Alternative World Views

Traditionally, scenario analysis starts with an initial forecast which is called the base case or reference scenario. Then alternative assumptions are made of initial conditions, equations and parameter values. The resulting projections are called *scenarios*. Differences between the scenarios and the references are used to evaluate uncertainties and possibilities of policy to influence the future. However, due to the implicit assumptions within every model, one reference scenario will not be enough to assess policy options. In fact, a set of reference cases should be used, which capture the main variety in alternative assumptions (Rotmans and de Vries, 1997).

Scenario analysis should be seen as computer-aided storytelling, where different stories can serve as a starting point for analysis. Analyzing policy options for different types of futures, can give insights into the robustness of these policies. Explicitly using different starting points can reduce the illusion that model-based analyses are objective predictions. In such a way, models can serve as a medium for discussion instead of an electronic oracle.

CHALLENGES FOR THE FUTURE

Important weaknesses of current modeling activities, related to human dimensions of global environmental change, are the inherent subjective assumptions of parameter values and relationships, and the fact that macro-relations are used of phenomena which emerge from local interactions between agents.

The challenge in the coming decades will be to use new developments in modeling tools and the use of models to overcome current problems. A promising start can be made when models are used in a more explorative way. Current models are often used as truth-machines. But the predictions, the glimpses of the future derived from electronic oracles, should not be our main interest. Since the future is inherently unpredictable, models should be used to enrich our insights into the behavior of complex reality. Improvements of our mental models can help us to improve our decision-making.

The concept of complex adaptive systems can be a promising starting point to think about new ways to develop and use models concerning human dimensions. Systems evolve, and therefore models assessing the future should focus on evolution and change. This requires the inclusion of disciplines nowadays not highly involved in modeling, such as psychology, institutional science, history and anthropology. Modeling human dimensions of global environmental change is a way of managing uncertainty and complexity. The tools discussed in this article can help us to experience and learn this art.

Modernity vs. Post-modern Environmentalism

Daniel R White

Honors College, Florida Atlantic University, Jupiter, FL, USA

Postmodern environmentalism provides a critique of, and a set of alternatives to, modern industrial society. It criticizes the separation of science from ethics and aesthetics, its separation of nature from culture and self from other, its Eurocentrism, and its sexism. As alternatives, it offers interdisciplinarity, reconciliation, multiculturalism, and ecological feminism. In place of modernist logical hierarchies and categorization of the world into things, postmodern environmentalism provides a communicative paradigm emphasizing metaphoric comparisons and interchanges among diverse inhabitants of the human-ecological community. Finally, this new outlook combines technology and nature in the creation of an emerging form of human-ecological identity, called the cyborg.

*Postmodern environmentalism is related to post-normal science (*see *Post-normal Science, Volume 5) in the following ways: (1) both are concerned with complex systems; (2) both offer a critique of the specialization and dogmatism of normal science; (3) both reintroduce value judgements (as in ethics and aesthetics) and environmentalist politics into policy decisions involving the natural sciences.*

Both environmentalism and postmodernism mark fundamental changes in the status and viability of modernity. The two movements converge insofar as they focus on those features of modernism that have contributed to the ecological crisis. *Ecology* originally meant the science of the household, and as such should be concerned with the rich variety of activities that create and sustain our daily lives: everything from the construction and maintenance of the human habitat to the plurality of biotic processes intrinsic to life on Earth. According to the environmental and postmodern critiques, modernity has increasingly undermined this human-ecological variety to create a world industrial order and a global monoculture. Under the sway of this simplifying modernism, the diversity that has made up the human household and the planetary biotic community has been externalized, devalued and oftentimes destroyed. Environmental and postmodern thinkers have therefore sought to revitalize ecological and human diversity.

The problematic aspects of modernism that are the focus of both environmental and postmodern critiques include:

1. the specialization of thought into separate realms of science, ethics and aesthetics;
2. the separation of culture from nature;
3. the binary demarcation of human from non-human;
4. the definition of self or mind as a subject having dominion over an objectified natural world;
5. the identification of that subject with Western culture and the masculine gender.

The combination of these modernist ideas has, according to environmental and postmodern thinkers, contributed largely to the ecological crisis.

The replacement of these problematic features of modernism with viable alternatives has become, therefore, a principal aim of environmentalist and postmodern thought. Both movements, accordingly, emphasize interdisciplinary thinking that re-links science, ethics and aesthetics. Both argue that cultural concerns like knowledge, value and beauty are in part derived from and have consequences for the natural world. Both make clear that the human and the non-human are inseparable aspects of ecological communities. Furthermore, both attempt to provide new forms of communication for the interdisciplinary study of ecological and human identities and relations. Finally, both emphasize the value of cultural and gender diversity, particularly the contributions of non-Western peoples and of women, to the creation and maintenance of the ecological household.

Postmodernism often invokes metaphor rather than logic to express its ideas. So it is appropriate to say that environmentalist and postmodern ideas have become interwoven in a new tapestry entitled *postmodern environmentalism* on whose fabric new forms of thought and action are appearing.

Box 1 Some definitions

modernity: The broad cultural movement from the 16th through the 20th centuries, focused on the idea of progress, and particularly on the betterment of human life through science and technology. In standard Western philosophy (epitomized by the work of Immanuel Kant) it includes the partitioning of knowledge into three spheres of inquiry: science, ethics, and aesthetics.
postmodernity: A cultural movement of the late 20th and early 21st centuries, based on the perceived failure of modernity to achieve its goal of human progress. It focuses on the ideas of cultural, social, and biological diversity, the rights of women and minorities, multiculturalism, and environmentalism. In philosophy it emphasizes interdisciplinary connections among the spheres of modernity (science, ethics, and aesthetics).
environmentalism: A contemporary philosophical movement advocating the legislative, political, ethical, and aesthetic defence of ecosystems as well as the preservation of a sustainable human ecology. Its outlook implies an *environmentalist* critique of modern industrial technologies insofar as they reduce biodiversity and undermine the viability of ecosystems to support life.
cyborg: A ''cybernetic organism'' of ''bionic human'' (Merriam-Webster). A new postindustrial form of technology based on the communication sciences. Still in its initial stages of development, the cyborg is increasingly capable of autonomous behavior simulating human conduct. It is therefore an innovative hybrid of nature and culture. Cloned organisms, including the biologically engineered human beings on the horizon, are examples of cyborgs.
teleological: an adjective based on the Greek words *telos* (purpose) and *logos* (word, or explanation). Teleological means ''purposive'' or ''designed'' or ''explained in terms of purpose or design''. In the information sciences it has largely been replaced by the adjective ''teleonomic'', based on *telos* and *nomos* (usage, convention). Teleonomic means ''simulating purpose'', or ''the quality of apparent purposefulness in living organisms that derives from their evolutionary adaptation'' (Merriam-Webster). Teleological explanation was rejected by modern science because it was associated with premodern ideas of design embraced by theology. *Postmodern* and *post-normal* science (*see* **Post-normal Science**, Volume 5) employ teleological or teleonomic explanation, as part of their reintroduction of ethical and aesthetic ideas (including those of purpose and design) into environmental discourse.

In standard modern philosophy, natural science requires the empirical description of nature without ethical or aesthetic considerations. Standard ethical thought, in turn, deals with *what ought to be* while science deals with *what is*. Aesthetics, similarly, deals with questions of beauty and sublimity (awe) that are neither factual nor ethical but, instead, are matters of taste. It further considers *teleological* (or *teleonomic*) questions about the apparent design of living things. See definition of *teleological* in Box 1.

Environmentalist and postmodern thinkers, in response, have argued that the description of nature or any object involves ethical and aesthetic dimensions. To select an object for description, e.g., requires that it be differentiated in value from some other object or as a figure against a background. That differentiation in value may be either ethical, in that the selected figure is chosen because it ought to be studied, or it may be aesthetic, because it is pleasing to study. In either case, the choice is teleological, in that it selects an object in terms of the purposes of the researcher. The observer of the natural world may also attribute some intrinsic purpose to it. Yet, these ethical, aesthetic and teleological dimensions are excluded by the modernist description of nature. They are relegated to specialists in disciplines outside of science.

The demarcation of culture as separate from nature, as well as human from non-human, is also typical of the modernist description of a natural object, say a tree. *Tree*, after all, is a word. In the terminology of linguistics it is a *signi er*, which denotes a signified concept which in turn denotes a perceived object such as the familiar configuration of trunk and branches. In postmodern terms the cultural activity of naming is part of the nature described by the word. The tree cannot be referred to as a natural object without the cultural activity of naming, i.e., it belongs to the whole system of what we mean by nature.

The description of a tree therefore implies a linguistic system. According to linguistic theory, the selection of the signifier *tree* and its associated concept displaces all of the others that might be chosen. Hence the *tree* and the *not-tree* are two aspects of the same binary system of language, the same code. To demarcate the tree from all that is not-tree, thereby saying that it must be treated as a separate entity, is an initial arbitrary act by scientific modernists, yet it involves the very ethical or aesthetic judgments that modernism would exclude from science. To treat the tree as a separate entity cut off from its linguistic system, furthermore, is analogous to cutting it out of the ecosystem – an act that has not only biological but also ethical and aesthetic consequences.

From the perspective of postmodern environmentalism, this amounts to separating the tree from the forest and its inhabitants. The cutting is done by a self considered to be separate from nature. The separation of the self from nature is typical of the Western cultural tradition. That this kind of subject is built into the descriptions of science indicates that modern science, at least, is an artifact of the same tradition – science is cultural. The scientific self is typically male and, in the view of postmodern environmentalism, objectifies the feminine body of nature based upon masculinist preferences: power, profit and control. Postmodern environmental science, therefore, promises to be feminist and multicultural, as well as communicative.

To learn how to see the forest and the trees simultaneously, postmodern environmental science has invoked the theory of communication. This theory focuses on the forms of connection and exchange between living things, e.g., on the interchange of words between speakers, or signals between computers on the Internet. It, furthermore, models organisms as artifacts or cyborgs emergent from the communicative processes of evolution.

A *cyborg* is an arti cial organism, a creature that is a hybrid of biology and technology. It is therefore, in the broadest sense, a work of ction: it has been made up from the elements of nature and culture. *Cybernetics* is the science underlying the construction of cyborgs. It is based on a broad analogy between the behavior of organisms and machines. Its central question is, What must we assume is going on inside an animal or a robot that allows it to act in an apparently purposive manner? The answer is that both must be in communication with their environments. Communication, in turn, is de ned in terms of negative feedback: a technical way of saying that an organism or a machine selects a particular course of action by excluding alternatives. In terms of communication theory, e.g., in order to catch a y, a frog must rst exclude all of the alternate courses of action the insect might take. By so doing, it selects the course the y is on. The frog then lashes out its tongue to the point along the course where the y will be when the tongue arrives. A guided-missile frigate would use the same negative logic to shoot down an incoming aircraft, and presumably so would you or I as we reach to catch a ball arcing toward us over a baseball eld. The frog, frigate or ball player might be organism or machine or human: the requirements for selecting a course of behavior based on negative feedback are basically the same. This selection is, in turn, teleological, ethical and aesthetic: the purpose, choice, and preference of the organism or machine or human being are intrinsically bound up with its selection of a course of action.

The cyborg is a de nitively postmodern construction because it breaks down the boundaries between culture and nature: it is a hybrid of cultural and natural processes understood in terms of communication. As the design science underlying the cyborg, cybernetics would view the forest and the trees simultaneously by providing a recursive vision of nature and culture. Negative feedback, paradoxically, includes a description of courses of action it must exclude in order to select its object. Because the process of feedback takes place in time and space, it must continuously update the position of the subject (frog, frigate, human) in relation to the object (y, aircraft, baseball). You and I must keep our eye on the ball if we want to catch it, constantly adjusting our position relative to the incoming y (so to speak). The full description of subject and object at any time must also include, as we have seen, the relative positions of and alternative actions excluded by both. If the ball were alive and capable of adjusting its own actions by negative feedback, like the hedgehogs that serve as croquet balls in the Queen s famous match in Lewis Carroll s *Alice in Wonderland*, then our game would be all the more complex (as it is, indeed, for the frog or frigate).

Think of the subject s position as being on one side of a circuit and the object s as being on the other. Consider the subject s descriptions of the object to be messages in that circuit. Now the messages in the circuit will re ect a spiral of differences between a series of subject and object positions. In this spiral, the description of the object must include a description of the subject (because they are always relative to one another) so that the overall system becomes self-referential. A self-referential system is recursive insofar as it refers back to itself, constantly revising its self-image. Your description of the incoming baseball must include a description of your position relative to the ball, and that description is constantly shifting as you and the ball approach one another on the eld.

This constantly self-correcting ensemble of subject and object is a good de nition both of the cyborg and the postmodern self. Both are hybrid artifacts generated by recursive communication in which subject and object are constructed within a spiral of differences. The spiral ultimately includes subject and object, self and other, culture and nature, trees and forest, in a postmodern-ecological design. That design has utility for survival because it yields a coadaptive evolutionary relationship between each of the aforementioned dichotomies. This relationship is precisely what the modern idea of nature lacks and the postmodern idea provides.

Muir, John

(1838- 1914)

John Muir, naturalist, explorer, writer, and conservationist, was born in Scotland. The Muir family emigrated to the US in 1849, settling in Wisconsin. His childhood was harsh and work-filled, but at an early age he became a keen observer of the natural world and an accomplished craftsman.

In 1860, Muir entered the University of Wisconsin, and in 1863 he traveled across the largely untouched northern US and Canada. In 1867 he suffered an eye injury while working. While he soon regained his sight, the event was to change Muir's life. He turned to nature. Muir walked from Indianapolis to the Gulf of Mexico; sailed to Cuba and Panama, and then in 1868, up to San Francisco. California became his home.

In 1868, he journeyed on foot through meadows, wildflower fields, and into the high country of the San Joaquin Valley. Later he wrote: it seemed to me the Sierra should be called not the Nevada, or Snowy Range, but the Range of Light ••• the most divinely beautiful of all the mountain chains I have seen. In 1874, he began a series of writings titled *Studies in the Sierra*. Fame ensued and his works were soon known throughout the US. In 1880, he met his future wife Louise and later they had two daughters. He entered the farming business with her father, and prospered.

Muir continued to visit the Sierra Nevadas, and traveled extensively abroad, eventually seeing all the corners of the globe. He also returned to writing, publishing articles and books about his travels and naturalist philosophy. Muir's writings assumed a spiritual quality that inspired his readers with his love for nature. In 1890, due in large part to the inspiration of Muir's works, Yosemite National Park was created. Muir was also the catalyst for the creation of Grand Canyon, Sequoia, and Mount Rainier parks. In 1892, Muir and friends founded the Sierra Club, as Muir stated to do something for wildness and make the mountains glad (Muir remained Club president until his death in 1914).

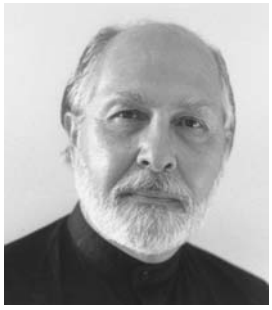
In 1901, Muir published *Our National Parks*, a work that was to become quite influential. He also formed a friendship with Theodore Roosevelt and Gifford Pinchot, a connection that was to have an important impact on the development of American conservation policy. Muir and the Sierra Club worked to protect the Sierra Nevadas. In 1913, a dramatic battle was fought; a campaign to prevent the damming of the Hetch Hetchy Valley, which was then within Yosemite, but the battle was lost. The valley was dammed to supply water and electricity to San Francisco, and to break the City's reliance on a private utility monopoly. However, the event had a galvanizing effect on supporters of the National Parks. The incident also ended his friendship with Pinchot, who had supported the project. Muir died the following year.

John Muir has been called the father of the American National Parks system. He was certainly one of the most influential and powerful of the early conservationists. John Muir's ideas and writings have had a lasting impact and legacy on the environmental movement. The Sierra Club is now among the most influential global environmental organizations (*see* **Sierra Club**, Volume 5).

KEVIN HANNA *Canada*

N

Nasr, Seyyed Hossein



(1933-)

Hossein Nasr (Seyyed is an honorific title designating a descendant of the Prophet Muhammad) has long been the most visible proponent of environmental values from an Islamic perspective, and is one of the most significant contemporary Iranian philosophers. His approach follows the perennial philosophy associated with Frithjof Schuon, Titus Burckhardt and Rene Guenon, in which timeless truths are seen as being expressed in a variety of historical cultural and philosophical traditions.

Nasr was born in Tehran, Iran into a family of scholars, physicians and Sufis (Muslim mystics). From secondary school onward he was educated in the US, first at the Peddie School in New Jersey where he was class valedictorian, then the Massachusetts Institute of Technology (MIT) where he received an honors degree in mathematics and physics in 1954. He went on to study at Harvard, where he completed a doctorate in the history of science in 1958. He then returned to Iran where he taught philosophy and the history of science until the revolution of 1979. In 1963, at the age of 33, Nasr became the youngest full Professor of the university. He served as Dean of the Faculty of Letters from 1968–1972 and briefly as Vice Chancellor. In 1972, the Shah appointed him Chancellor of Aryamehr University, a new technical institution modeled on MIT. The following year, under the patronage of the Queen, Nasr established the Imperial Iranian Academy of Philosophy, which hosted the eminent scholars Henri Corbin and Toshihiko Izutsu, among others. Following the 1979 revolution, he returned to the US, where he taught first at the University of Utah, then Temple University, and finally at the George Washington University, where he has been University Professor of Islamic Studies since 1984. He has also held visiting positions at Harvard, Princeton, and the American University of Beirut. In 1981, he became the first Muslim to deliver the Gifford lectures at Edinburgh.

One of Nasr's major contributions to the field of education, especially during his years in Iran, was his emphasis on approaching the study of Islamic philosophy and science from the perspective of his students' own Islamic and Iranian traditions, in contrast to the external approach of Western Orientalists. He thus strove to bring about a synthesis drawing on the strengths of both Western and non-Western intellectual traditions.

Alongside his academic pursuits, Nasr has also sought knowledge through traditional means, such as the largely oral transmission of learning from master to disciple characteristic of Sufism. In this context he studied Islamic philosophy and other disciplines under the tutelage of Mohammad Hossein Tabataba'i, Abo'l-Hassan Qazvini, and Mohammad Kazem Assar.

Anticipating the well-known 1966 critique of his fellow historian of science Lynn White, Jr, in his Rockefeller lectures at the University of Chicago earlier the same year (subsequently published as *Man and Nature: the Spiritual Crisis in Modern Man*), Nasr argued that the emerging environmental crisis was rooted in a spiritual crisis. He has taken up this theme in many of his later writings, including his Cadbury lectures at Birmingham in 1994, which were published as *Religion and the Order of Nature* in 1996.

National Environmental Law

M J Peterson
University of Massachusetts, Amherst, MA, USA

National environmental law comprises those branches of the national law of each state addressing human interactions with nature, focusing primarily on protecting the biosphere - including its subsystems, processes, and species diversity - from avoidable signi cant harms arising from human activity. National-level environment law-making, like the counterpart process at the international level, is affected by the special characteristics of environmental problems: high uncertainty about the effects of human activity on the biosphere, heavy reliance on scienti c, engineering, and economic expertise in the formulation and enforcement of legal rules, necessity of considering long time horizons, and complexities of ensuring compliance among a wide range of private, quasi-public, and public actors.

National legal systems have long addressed land and water use, resource management, public and private construction, health and sanitation, food safety, and waste treatment, but environmental law did not emerge as a separate branch of national law with its own statutory basis, administrative organs, and jurisprudence until the late 1960s and early 1970s. Environmental laws adopted in the 1970s focused primarily on control and reduction of pollution, wastes, and hazardous or toxic substances. Their scope has broadened in subsequent decades as societies have realized that many human activities have signi cant effect on the natural environment. Thus, by the mid 1990s it was possible to de ne environmental law in very broad terms as the body of law intended to minimize the impact of activity by individuals, households, business rms, other private and public legal entities, and government agencies on natural ecosystems and resources (e.g., McGregor 1994). However, the de nitions that guide actual legal practice continue to focus primarily on the broad subject areas of air quality, water quality and use, biodiversity and wildlife management, environmental impact and risk assessment, control of hazardous and toxic substances, remediation of hazardous substance contamination, and liability for pollution damage (e.g., Rosencranz, 1991; Baker, 1997; Findley and Farber, 1999).

CHARACTERISTICS AND DEVELOPMENT OF NATIONAL ENVIRONMENTAL LAW

National environmental law shares the main features of other branches of national law. First, it operates within a centralized political system based on a hierarchical relationship between government and governed. The government holds rights to prescribe, apply, and enforce the law to all individuals, other private legal entities, and subordinate public entities that are its nationals and to those private individuals and entities of foreign nationality operating within the state's land, maritime, and aerial domain. In turn, those entities have an obligation to obey. Individual states' political systems vary considerably in the extent to which they provide effective governance, allocate governmental authority among different levels (e.g., federal, provincial, and local), maintain mechanisms for holding government officials accountable to the citizenry, and incorporate *bottom up* initiatives in policy-making, but all ultimately rest on a hierarchical organizing principle. Second, national legal systems contain several types of rules, each with a distinctive function in the overall legal system. Rules of recognition, some pertaining to the national legal system as a whole, and others to environmental matters in particular, stipulate how laws, regulations, and customs are adopted, amended, or repealed. Substantive rules perform any or all of three functions:

- *constitutive rules* define types of actor, conduct, or situation;
- *regulatory rules* stipulate the forms of conduct to be adopted or avoided in particular situations;
- *consequential rules* specify what can happen to actors as they conform or fail to conform to substantive rules.

In addressing air pollution, for example, any national legal system must contain constitutive rules defining what types and levels of emission constitute pollution, regulatory rules outlining how actors producing emissions should act to control those emissions, and consequential rules establishing rewards for compliance or (more commonly) punishments for non-compliance with the regulatory rules. Finally, environmental law's actual impact on actor behavior depends on varying combinations of willing support for the particular legal rules, more diffuse law habits that incline actors to respect the law in place even when they disagree with certain of its stipulations, material inducements to comply and material punishments for non-compliance.

The chronology of efforts to develop national environmental law is very similar around the world, a reflection of the strength and success of transnational and intergovernmental efforts to increase the salience of environmental concerns among governments and private actors alike. Concern about the impact of industry, agriculture, and urban life on the general condition of the air, lakes, rivers, and streams and waterways, and strong public demands for reducing air and water pollution, emerged in North America, Western Europe, and Japan at about the same time in the mid to late 1960s, as a product of changed beliefs about the origins and desirability of pollution. Though concern about air and water quality inspired national legal regulations in the

19th century (e.g., the British Alkali Inspectorate Act), even in 1950 the urban fogs, composed of smoke and particulates emitted by electricity generators, building heating or cooling systems, and factories, were viewed as unavoidable by-products of industrial prosperity despite awareness that urban dwellers experienced higher incidence of respiratory diseases. Within 15 years, governmental and popular attitudes had been transformed: greater concern about the human health effects of poor air quality, plus the diffusion of ecological worldviews conceiving of the biosphere as an interrelated whole in which change in one part had significant ramifications through all other parts, had transformed perceptions of pollution. Smoky emissions were no longer perceived as a sign of industrial might and prosperity, as a quasi-natural phenomenon beyond control, but as a bad that could be reduced or avoided through concerted human action. Incorporation of these changed perceptions into national policy was signaled by the US Clean Air Act of 1970, the first Japanese pollution laws of 1970, the German Federal Environmental Program of 1971, and the first European Community Environmental Program in 1973. Though some Leninist leaders continued to maintain that environmental degradation was a by-product of a private enterprise economy, the Union of the Soviet Socialist Republics (USSR) and its Eastern European allies had also begun adopting environmental laws.

Though the characteristic environmental problems facing Third World countries were different – stemming far more often from inadequate access to safe water, fuel, and sanitation than from industrial emissions – perceptions of a need for national environmental law were diffused rapidly to Third World governments through the preparations for and holding of the 1972 UN Conference on the Human Environment in Stockholm. While insisting at the Stockholm Conference and later multilateral negotiations that international environmental law must not become a vehicle for frustrating their own development efforts, Third World governments did accept the need to begin incorporating environmental concerns into their own national laws. India adopted its first explicitly environmental statutes in the early 1970s, though it developed a comprehensive framework statute only in 1986 after the Bhopal chemical leak revealed significant weaknesses in India's environmental law, and created strong public pressure for strengthening it. The Chinese government appeared unimpressed with concerns about the environment at the Stockholm conference, but some of its leaders were paying attention to pollution problems and other environmental concerns even before the political and economic reforms of the 1980s. Statutory changes were paralleled by administrative reorganization. The increased importance attached to environmental concerns was institutionalized by the establishment of an umbrella environmental body to coordinate governmental and private action. These bodies, often cabinet-level agencies or ministries, were established in the major Western industrial countries during the early 1970s and in most other countries during the 1970s and 1980s (Baker *et al.*, 1985; Janicke and Weidner, 1997).

The extent of change in substantive legal rules inspired by new concern with the environment, and the process by which it was accomplished, have varied from country to country, depending partly on governmental and public perceptions of the nature of environmental problems and the means available for their management, and partly on the national legal rules specifying how revision of substantive law should be accomplished. Because each national legal system has its own balance among statutes, judicial decisions, and customary practices as sources of law, the process of accommodating contemporary ecological awareness into law has thus differed sharply. In the UK and the civil law states of Europe, the primary emphasis has been on legislative amendment of the law codes. In the common law systems of Australia, Canada, India, New Zealand, and the USA, the process has involved a combination of legislative action and active judicial refinement of common law doctrines. In most Third World countries, the process has also involved legislation, but to varying degrees has also featured reinterpretation of traditional customary rules still used in the mix of indigenous and European-inspired law that forms the contemporary legal system. The global spread of problem definitions, relevant scientific knowledge, information about possible regulatory approaches, and model laws, encouraged by non-governmental environmental organizations like the World Wildlife Fund, Greenpeace International, quasi intergovernmental ones like the World Conservation Union, the United Nations Environment Programme, and other global or regional intergovernmental organizations, has not erased national differences, but has meant that there is considerable common ground in environmental discussions. International environmental agreements have also created a body of common goals for those states that have become parties, and on some occasions provided developing states with financial and other resources needed for effective monitoring and enforcement.

BASIC PRESUPPOSITIONS OF NATIONAL ENVIRONMENTAL LAW

Though some environmentalists have argued for treating nature generally or other species of life as having distinct legal rights apart from those of humans, national environmental law systems are generally based on constitutive rules that classify humans – individually and in their various collective groupings – as the subjects of law-holding rights and duties and responsible for their actions in complying or not complying with the law. Natural places and resources are classified as objects of law that the subjects of law may or may not use in particular ways as they go about their

activity. Individuals (natural persons) and collective entities (legal persons) are most often connected to natural places and resources through property rights regimes, which define who may have access to what places on what terms and may put any resources found in those places to use, either *in situ* or by removal for purposes of providing fuel for human activities requiring energy inputs of heat, light or power or for working, into tools and other usable objects.

Property rights regimes vary on several dimensions, but the most important involves the basis of de ning access rights. Four possibilities have been most prominent in human history: *open access*, *community property*, *individual property*, and *controlled access*. Under an open access regime, a particular natural place is open to anyone who can reach it, and any resources within it are open to use *in situ* or after being carried away on a rst-come rst-served basis. Little law is needed, other than prohibitions against attempts to close off the area. In community property regimes, which are historically far more usual than open access ones and formed the subject of Hardin s famous tragedy of the commons (*see* **Commons, Tragedy of the**, Volume 5), access is limited to members of a particular community most often de ned by geographical proximity or traditions of seasonal use who may use resources *in situ* or take them away according to community norms about shares. Local customary law most often governs membership in the community and members resource use; under modern conditions, the national legal system is needed to provide protection by af rming community property, and protecting it from intrusions by outsiders. In individual property rights regimes, an individual, household, or legal person enjoys exclusive access to the place that is its property and controls all resource use. In most national legal systems that property-holder (typically called the *owner*) may use the place or resources directly, rent or sell the place or resource rights to others, or leave the place and resources unused. Under controlled access property regimes, places and resources are governed by a central authority, which determines who may enter on what conditions and use resources *in situ* or take them away. Much of the debate regarding environmental law focuses on the relative advantages and disadvantages of each type of property rights regime for promoting environmental protection and sustainable uses. Most national legal systems assume that open access regimes are not viable for contemporary levels of population and intensity of resource use; they institutionalize varying degrees of reliance on community property, individual property, and controlled access regimes. Western legal systems, common law and civil law alike, rely most heavily on individual property rights regimes, though certain forms of community property and of controlled access through government licenses exist as well. Community property regimes are more common in non-Western systems, though they vary considerably from place to place. They coexisted with individual property rights even before colonial era impositions of individual property rights regimes by European powers, and are enjoying some revival today as scholars demonstrate their viability as modes of regulating resource use (e.g., Berkes, 1989; Ostrom, 1990). Bad experiences with Leninist central planning have discouraged primary reliance on controlled access through central licensing, but such systems remain in place for particular areas or activities in most countries.

Property rights regimes establish who is responsible for the use of a particular area and its resources, but do not guarantee environmentally sustainable patterns of activity. Most national environmental law is built on the basic assumption that environmental degradation occurs because individuals, households, rms, and other entities have no incentive to pay attention to the environmental burden of their activity, as long as they can pass all or part of the costs of coping with that burden to others. Thus, the primary task of national environmental law is to limit or even prevent such transfers. Successful prevention requires a variety of legal instruments because such transfers can occur geographically, economically, or temporally, and each type is best addressed through somewhat different rules. Geographical transfer occurs when wastes or pollution are allowed to spread beyond the edges of an actor s own property, and are inhibited through substantive legal rules prescribing that ownership or other property rights do not include a right to cause harm to others or their property, and through procedural norms requiring property holders to control harm equally stringently, regardless of whether it occurs on or off the property. Economic transfers occur when one actor s activity degrades a common resource like water or the atmosphere, leaving others to pay for coping with the degradation. Economic transfers are inhibited through the polluter pays principle and emissions charges, water or land use fees, charging cleanup costs or nes for excessive emissions that reinforce nancial incentives to avoid across-actor transfers. Transfers across time occur when actors handle a problem with a quick x, such as underground storage of highly radioactive wastes, which leaves the basic environmental problem to be solved later at considerable expense. These transfers are inhibited by legal norms lengthening time horizons, such as intergenerational equity, the precautionary principle, and mandatory prior environmental impact assessment. Since most national legal systems have permitted such transfers in the past, and actors came to view such transfers as part of life, regulation to limit or end such transfers strains previously held beliefs and will remain a source of resistance to environmental law until ecological awareness, social mores, and habit make avoidance of such transfers the basic pattern of social behavior.

Environmental law has been a particularly dynamic branch of national law in all countries, marked by a high

rate of legislative, administrative, and judicial activity for several reasons. Public concern about the environment has expanded to encompass more problems, creating demands for more regulations. Improved scientific understanding of ecosystem dynamics, and the impact of human activity on those dynamics, has been a source of demands for additional regulations or reformulations of existing ones to take advantage of current knowledge. Technological change in particular sectors of the economy, together with the broader shifts in patterns of production and distribution of goods and services resulting from the increasing volume of cross-border transactions, and the transition from the mass production-mass consumption pattern of the 1950s to the current information-intensive and flexible production pattern, have also required adjustments of legal rules.

The most widespread change in the national legal context has been a shift in the general approach to limiting inter-actor transfers of environmental costs. Most of the pollution control legislation adopted in the 1970s relied on a command and control regulatory regime, under which designated government agencies were given authority to determine environmental standards and to define the means by which other actors would meet those standards (*see* Demand Management, Volume 4). Thus, the US Clean Air and Clean Water Acts authorized the Environmental Protection Agency to determine national air and water quality standards and then to stipulate the technological means by which users or air or water would control their emissions so that the standard would be met. Command and control operated more flexibly in countries like Japan and the UK, where statutes establish broad guidelines which government agencies apply flexibly through discussions with industry, and there is a strong emphasis on abating pollution through use of specified pollution control or cleanup technology. In India, it took the form of attaching conditions to permits for business activity, an environmental extension of the well-established license raj approach to regulating private firms' general business activity.

A command and control regulatory regime has the advantages of ensuring uniform standards throughout the territory of the state, assuring that all actors accomplish some minimum degree of environmental protection, and placing all firms under similar cost burdens. Yet it also has the disadvantages of cumbersomeness, since a central agency has to make far-reaching and highly detailed decisions and, at least as applied in many countries, an inflexibility inhibiting adjustments to local conditions. While a command and control approach can, in principle, promote technological innovation through adoption of progressively tighter emission limitations and other technology-forcing devices, in practice it often inhibits innovation because firms and others have no incentive to do anything but adopt the government-mandated pollution abatement technology.

By the mid 1980s, the problems with command and control regulatory regimes were being criticized from two distinct standpoints. One, generally identified with the political right and neoliberal economic theory, argued for replacing command and control with market-based measures altering actors' propensity to create environmental harm either by increasing the cost of causing harm or subsidizing harm avoidance. Advocates argued that measures like emissions taxes, tradable emissions or resource extraction permits, and rules permitting firms to choose how they will meet government-determined emissions or ambient quality standards, would yield greater environmental improvement at lower cost than the command and control approach. The other, generally identified with Green parties and other elements of the political left, argued that central regulation should be replaced by a radical decentralization of authority, transformation of production and consumption patterns away from energy and resource-intensive consumerism towards localized self-sufficiency, and a populist emphasis on local knowledge and local justice. Both views share a skepticism of centralized government: the first prefers heavier reliance on private ordering through contract while the second prefers local self-organizing as a way to resist capture of the law-making process by corporations and experts. Though most forcefully expressed in the USA, market-based approaches grew more influential in many countries during the 1990s. This shift reflected some experience with particular command and control regulatory regimes, but even more the problems of centralization, opacity, and non-accountability encountered in countries where state-owned enterprises operate all or most major industries. These were most obvious in the USSR and other Leninist states.

As reliance on market-based measures increased in the 1990s, criticisms of such reliance continued. Advocates of local self-sufficiency continued to make their case for a complete turning away from industrial ways of life. A broader coalition, ranging from the socialist left to the center, continued to support government regulation though seeking greater transparency and accountability in corporate and governmental activity. Demands for greater public participation in environmental decision-making were reflected in support for prior environmental impact assessment, right-to-know laws regarding hazardous substances and workplace safety, access to government-held information (freedom of information laws) and opportunities for public comment before major public projects began. National environmental law in most countries thus remains the subject of considerable contention as actors pursue both their immediate concerns and their visions of how society as a whole should function.

National environmental law has also been affected by the ongoing debate about how to specify the desired environmental conditions. Law-making in the 1960s and 1970s was

marked by strong debate between advocates of regulating by emissions standards, which would specify the maximum amount of pollution that could be released by any single pollution source (such as a power plant, factory, or vehicle), and by ambient standards, which would specify the maximum acceptable level of each particular form of pollution (such as sulfur dioxide, nitrate, or lead) in the water or air. The debate about the relative merits of focusing on the individual sources of pollution, or the aggregate effects of pollution-generation, was eventually resolved in a both/and fashion, in which ambient standards provide the baseline from which regulators determine whether and how to regulate individual emitters. More recently, the connections between particular emissions of pollution and the ambient air or water quality have been drawn more precisely by using the *critical loads* methodology to determine acceptable pollution rates by reference to the absorptive capacity of the air, water, land, or vegetation of an area, as well as ambient air or water quality (*see* Critical Load, Volume 3).

Almost all national legal systems must also address problems that arise from fragmentation of governmental authority. This is most obvious in federal states where lower-level government units (states, lander, provinces, etc.) have constitutionally-protected powers, but also occurs in unitary states if actual management of certain activities is delegated from the national government to more localized authorities. In the Netherlands, for instance, 125 water boards, each responsible for a particular part of the country, administer many aspects of water use policy. The same dilemmas that plague development of international environmental law – whether standards should be uniform or respond to differences in local conditions, whether environmental measures in one area, such as recycling requirements, serve also or primarily as ways to favor local over outside firms, whether differences in standards trigger races to the bottom as firms seek to relocate activity to places with less stringent rules, or races to the top as firms conform to the generally stricter standards prevailing in the industrial states so they can sell in those markets – mark the development of national environmental law. This is particularly noticeable in large federal states like India or the USA, and is also prominent in efforts to develop European Union (EU) environmental law.

ENSURING COMPLIANCE WITH NATIONAL ENVIRONMENTAL LAW

At first glance, political centralization and organization of states along hierarchical principles appear to make the problem of securing compliance with national environmental law one of effective application of the administrative and coercive apparatus of the government. Yet even tight hierarchies founder if too many citizens react to law with inaction, grudging partial compliance, or outright violation. National legal systems typically seek to draw on all motivations for compliance present among the private and other actors whose conducts are addressed; advocates of different regulatory regimes simply place different degrees of emphasis on different motives. Advocates of command and control rely, in the last instance, on a strong administrative state capable of monitoring actors' behavior, identifying non-compliers, and imposing sanctions that will induce non-compliers to change their behavior. Advocates of market-based regulation rely more on aligning legal rules with actors' current self-interests or using law to change conduct by shifting actors' incentives to the point that compliance becomes more highly valued than non-compliance. Advocates of local sustainability rely primarily on persuasion to accept new values and beliefs, socialization into new norms of conduct and psychological desire to remain in good standing with others in the community. Yet when considering possible environmental law, advocates of all three share certain appreciations. All treat actors as responsible agents who are capable of thinking about their situation and making conscious choices. All assume the legal system will provide sufficiently clear rules that compliance can be distinguished from non-compliance. All assume that actor behavior and the legal process are both transparent enough that particular non-compliers can be identified and called to account, and that the legal system will afford opportunities for determining whether a particular instance of non-compliance is the result of conscious action, ignorance of rules (though most national legal systems do not accept ignorance as an excuse for non-compliance), accident, or intervening circumstance that made compliance impossible, before deciding whether a particular violation is best addressed through provision of information (about the environmental problem or about the law's requirements), assistance in overcoming inability to comply, incentive to comply, or punishment of failure to comply.

The national environmental law of particular countries use several mechanisms for securing compliance, with the mix actually used reflecting national legal traditions on the broad problem of promoting obedience to the law. National systems tend to place great emphasis on administrative elaboration of standards, monitoring of actor compliance, and imposition of penalties for non-compliance. The more heavily a national legal system relies on administrative elaboration and enforcement, the greater the burden on government agencies to recruit and retain technically qualified personnel capable of formulating rules that will produce the desired changes, and taking action when pollution or other environmental damage results from human activity. At the same time, no government relies solely on government personnel in environmental rule-making and enforcement. Administrative rule-making typically involves a degree of prior discussion

with the private and public actors likely to be covered by the rules. Though posing dangers of regulatory capture, in which the least enthusiastic of the regulated determine the pace and content of rules, prior discussion affords opportunities to exchange views, explain the rationale for particular rules, and secure target actors' perspectives on the feasibility or unfeasibility of different possible rules. Many national legal systems attempt to limit the danger of regulatory capture through provision for public comment on proposed regulations before they go into effect, or for prior discussions that include other groups likely to be affected by target actors' conduct (e.g., the government–labor–business consultations in the European corporatist systems).

Use of administrative rules requires establishment of systems for monitoring behavior. Many of these are mechanical; scientific instruments located at or movable to particular sites for direct observation of emissions or ambient air or water quality. Satellite-based remote sensing systems offer possibilities of monitoring changes in land use, vegetation patterns, and habitats as well as identifying sources of significant pollution plumes. Complaints from nearby residents or environmental groups, who do their own monitoring, often supplement administrative agency efforts.

Involvement of national courts in applying environmental rules varies considerably. In many common law countries, much environmental law was created as private persons or organizations, able to show they suffered direct damage to themselves or their economic activity from pollution, invoked common law notions of nuisance, negligence, and trespass against those responsible for the pollution. Dealing with pollution did require reinterpretation of these traditional concepts, but many judges shared the rising public concern and were willing to innovate. The flowering of public interest litigation, most notable in the USA and India, also required some changes in the rules defining who has a right to sue whom over what, to allow suits by environmental and other organizations rather than individuals or firms and to permit class action suits in which some of those harmed sue on behalf of all. The very high level of court involvement in formulation and enforcement of environmental law in the USA reflects that country's conditions, and has three main sources. First, the general common law emphasis on judicial interpretation has been much enhanced through the principle of judicial review, which allows individual citizens and other private entities to challenge the consistency of statutes or particular administrative actions with basic constitutional provisions including the Bill of Rights. Second, the national government's administrative apparatus is relatively weak compared to those of other industrial states, and many federal statutes compensate for that weakness by allowing individuals or firms to sue other entities for non-compliance or to sue government agencies over non-enforcement. This practice dates back at least to the Sherman Anti-Trust Act of 1890, and has been incorporated into the major US environmental statutes, even though the US Supreme Court has reined in the practice since the mid 1990s by narrowing the criteria for determining who is eligible to sue over what matter. Whereas environmental organizations file most of the citizen suits seeking better enforcement, business firms and other targets of environmental regulations are the source of most challenges to the constitutionality of some statutory provision or administrative act. Third, the separation of powers into three coordinate executive, legislative, and judicial branches of government often promotes judicial activism by emphasizing the courts' status as a coequal branch of government. Though sharing the common law tradition, the UK and many of the Commonwealth countries have parliamentary political systems where executive and legislative powers are fused, and courts defer more to parliamentary sovereignty in matters regulated by statute than do their US counterparts. In civil law states, the courts' role is even more constrained; there, administrative agencies and review panels are the primary mechanism for applying environmental rules and determining whether non-compliance has occurred; citizen suits are not institutionalized in the legal process and judicial review is limited to constitutional courts or courts of cassation (annulment) with authority to vacate (to make void) administrative actions. For states who are members of the EU, the provision for European Court review of national compliance with EU directives and regulations has created possibilities of regional judicial review.

Yet judicial activism can occur even where there is no formal separation of powers and no common law system. Japanese courts played a significant role in the initial development of environmental law in Japan, through judgments requiring businesses responsible for major pollution damage to provide extensive compensation to victims and pay punitive damages. Judicial activism has been more constant in India (a parliamentary common law state), despite a notoriously slow court system, where advocates of the poor and marginalized have taken up environmental cases as one part of a broader program of public interest litigation encouraged by the Indian Supreme Court's liberal interpretation of standing to sue, citizen suit provisions in Indian environmental statutes, and the distinctive Indian legal customs regarding writs of *mandamus* (which order a government agency to exercise its legal authority), prohibition (which enjoin a government agency from acting in a way contrary to statute), and *certiorari* (which remove a case from a lower court or an administrative agency to a higher one) allowing private citizens to sue government agencies for actions or inactions.

National environmental law thus exists at the confluence of well-established national legal traditions and increasingly

widespread knowledge about ecosystems and the impact of human activity on them. Differences in ecosystems, patterns of human activity, cultures, and legal traditions mean there will always be considerable variation in national environmental law. All national environmental law systems face the challenge of helping move societies from environmentally-oblivious to environmentally-aware modes of human conduct. Each will find its own way to ensure that national law and property rights regimes incorporate environmental values and that actors are discouraged from persisting in patterns of activity that shift the environmental burdens of their activity to others through geographical, economic, or temporal transfer. For an interesting comparison, *see* International Environmental Law, Volume 5.

Natural Law

see Nature (**Volume 5**)

Nature

Nature is notoriously difficult to define. In his touchstone definition in his anthology *Keywords*, the social critic Williams (1983) says that it is both perhaps the most complex word in the language and that any full history of the uses of nature would be a history of a large part of human thought.

In light of these sobering judgments, a short definition should simply point out the major distinctions in the use of the word, and some of the words with which it is often paired or compared.

The word derives ultimately from a cluster of terms around the past participle of the Latin verb, *nascor*, to be born; terms that include the use of *natura* as a noun indicating blood-relationship, physical affinity, etc., and that are generally associated with the idea of something having a nature or a quality of its own. This becomes linked with a second cluster of terms and meanings that suggest that there is a larger nature of things (perhaps with a capital N for Nature). Roman philosophers like Cicero and other Stoics intimated that *natura rerum* – the nature of things – might be an elemental god or physical force underlying all things. A third set of associations set the forces of nature (even the personified goddess Nature or the great god Pan) in opposition to the forces of civilization.

The first set of associations – something having a nature of its own – has a long subsequent history, ranging from the idea that to be natural is to be true to oneself, to today's claims that something is 100% natural. Natural here is being given the connotation of truth, purity and integrity. A different, but comparable idea is the Chinese concept of the *Tao* (the way), which suggests that the right path for human living is to match one's self to the moral structure (the Tao) inherently part of the natural world.

In the West, a related idea (traceable back to Cicero) is that of *natural law* – a law that does not need to be legislated because it is so obviously part of human experience, and allegiance to which aids human flourishing. This would have a long history, culminating (a) in the idea of human rights as inalienable because they are (if you subscribe to a doctrine of rights) part of the definition of what it is to be human; and (b) in various controversial claims about natural law by conservative institutions, e.g., slavery is natural, woman are naturally nurturing, homosexuality is unnatural, and so on.

In the Middle Ages, and into the Modern Era, the dominance of Christianity cast a suspicious shadow over all versions of being natural, that allied human nature with the natural world, when that world was seen as the pagan world of unredeemed physical nature. It was considered

to be tempting and dangerous, because it was disordered and distant from God. The ultimate Paradise of Christian mythology was either a redeemed garden (of Eden) or a city, Jerusalem. Wilderness was the place of demons and temptation, as it had been for the Israelites and Jesus both, as they wandered in the wild desert. For the medieval Christian, the important task was not to align oneself with the forces of wild nature, but with humankind's true nature which was in alignment with the ordering power of God. Human beings were exhorted to redeem their wild, corrupt nature by moving towards their second nature – a cultivated nature that had to be worked upon, and transcended. In several places in the Bible, Heaven is described as the city of light.

In the Romantic era (1750–1850), this third set of associations – nature versus cultivation – was turned on its head. Given the pressures of the Industrial Revolution, and the widespread repudiation of hierarchical political and social structures based on outmoded versions of order, romantic writers claimed a primal affinity with nature, because nature was now a place of refuge, and positively comparable as a complex, organic whole, to an increasingly alienated atomized machine culture. Nature was once again the original home from which human beings had fallen into civilization. The destruction of nature began to be seen as analogous to the increasing destruction of elements of human nature by the forces of industrialization.

This recasting of nature as positive has had a number of effects, not all of which are themselves positive. For example, the image of a pure primal energy force associated with nature – the life or death force – influenced the rise of Nazi blood politics. Other effects, which have still not been fully worked through, include the raising of fundamental questions about whether there is such a thing as human nature, whether human beings are lying to themselves when they consider themselves to be independent moral agents capable of rising above nature, and so on. On the other hand, environmentalism owes its very existence to the positive reevaluation of the need for unhumanized nature, and the protection of natural processes (which we do not fully understand) in the modern world.

Finally, it is worth noting that the second set of associations with which we began – Nature as a catch-all term for everything in the material world – is certainly widespread today in the sciences, where nature is synonymous with the natural world, that is, the physical world. Because of the complex web of historic and philosophical meanings attached to the term, however, it often causes confusion wherever different disciplines meet, especially across the physical sciences, social sciences, and humanities.

New Ageism

New Ageism is a diffuse, piecemeal movement of groups and individuals both inside and outside environmentalism. They share a conviction that the world is undergoing a major transformation, involving a shift in consciousness, towards a new mode of being. Contemporary New Agers follow the astrologers contention that a new age is entered about every 2000 years, maintaining that the Age of Aquarius is displacing the current Age of Pisces. Pisces has been dominated by polarization and con ict between cultures, civilizations, religions and races. Western consciousness has particularly been driven, through mistaken conceptions of reality as composed of irreconcilable dualities like mind and body, male and female, society and nature.

By contrast the Aquarian Age will be one of harmony, holism, balance and heightened moral and spiritual awareness. Society and nature will no longer be separated. Transition to the New Age will follow changes in the consciousness of some individuals. They will form disparate, scattered groups promoting such things as ecology, feminism, spirituality, etc., and will eventually coalesce to form a critical mass, catalyzing all peoples into the new thinking, thus creating a global consciousness. This process will be facilitated by advanced communications technology, such as the internet.

New Ageism draws on an eclectic mix of spiritual and other traditions, such as Eastern mysticism, Western religions (the ideas of the Catholic priest, Teilhard de Chardin, are seminal), alternative medicine, ecological science and new physics. Its idealistic analysis and prescriptions focus on changed attitudes as the spur to changed behavior. It rejects the materialist analyses of old-style politics, which analyze behavior in relation to economic class interests. Paradoxically, perhaps, New Ageism often revives

pre-modern beliefs, such as paganism, pantheism, animism and vitalism.

NIMBY (Not In My Backyard)

NIMBY is an acronym indicating that people living near a proposed development (e.g., waste dump, highway bypass, nuclear power station) strongly object to having the development situated near them, although they would not necessarily oppose the development if it were located elsewhere. A related expression used in parts of the USA is locally unacceptable land use (LULU).

Noosphere

The *noosphere* is a sphere of interaction between humans and nature where conscious human actions become a major determining factor of its evolution. The definition of noosphere has evolved from a spiritual notion to a more scientific one. Two French philosophers, Edouard Le Roy and Pierre Teilhard de Chardin introduced the term in the early 1920s. Teilhard de Chardin described the noosphere as the conscious and thinking membrane enveloping the globe, whose emergence was caused by the appearance of humans on the Earth and by the development of human intelligence. Vladimir Vernadsky, the Russian natural scientist and philosopher, gave a more scientific connotation to the word *noosphere*. He envisioned the noosphere as an inevitable evolutionary stage of the biosphere where human thought and activities become major forces in the evolution of the Earth. Given that humans can change the chemical composition of air and water, create artificial minerals, reroute rivers, and breed new types of animals and plants, their power to transform the environment is now comparable to the transforming forces of nature. Vernadsky saw anthropogenic environmental changes as inevitable, manifesting the beginning of a new evolutionary stage of the biosphere.

Phase Shifts or Flip-flops in Complex Systems

Henry A Regier[1] and

James J Kay[2]

[1]*University of Toronto, Toronto, Canada*

[2]*University of Waterloo, Ontario, Canada*

Living things self-organize into systems that must be partly closed to maintain identity and integrity, but must also stay partly open in order to accumulate high quality resources in categories such as mass, energy and information and to void wastes also belonging to these categories. A living thing must also stay partly open in order to interact, often reciprocally, with other living systems and with features of its non-living environment. Non-living things may also self-organize systemically, but in less complex ways. Living things in general have evolved capabilities to self-organize into a number of different complex phases, states or stages and to shift from one of these to another in response to changes in internal and external phenomena. Many living systems, especially organisms, have evolved capabilities to proceed autonomously through cycles of such stages. The life history of an insect, for example, exhibits a progression from fertilization to egg to larva to pupa to adult to dead body. Such a one-way or ontogenetic development with transformations between stages may be perceived as a special case of the kind of organizational changes that we focus on here; we do not include such specialized one-way cases in the present discussion. Instead, we focus on systemic reorganizations that occur between different relatively stable states of a living complex system and are reversible, more or less. (Of course, strict reversibility is not possible because living systems are subject to the second law of thermodynamics.) The kind of shifts on which we focus may occur abruptly and haphazardly in response to a particular kind of stimulus that is relatively unexpected and catastrophic in its context; or it may occur in a more orderly way for some stimulus that is always expected with significant probability in its context.

We emphasize that, for this essay, the concept of shift between phases has a similar meaning to flip between stable states, and a two-stage flip-flop between alternate states. We do not include a concept of ontogenetic, one way changes through a genetically pre-ordained series of stages; to do so would increase the scope of our essay beyond our present purposes.

We include as natural, some features of living things that some people would refer to as cultural. Some species such as humans may exhibit strong cultural features as well as the necessary natural features, while other species such as bacteria may exhibit few if any cultural features. We do not presume to understand fully any natural and natural/cultural features of reality that we address. Some people may perceive some features of humans and human societies to be both cultural and unnatural; our intent is not to include consideration of such unnatural features in the present essay.

The natural base of strongly cultural living systems must remain open to mass, energy, and information flows, as is the case with all living things. Cultural manifestations are also open culturally in that they thrive on such resources as beauty, ethical goodness, respect and caring and try to divest themselves of the opposite of these qualities; ugliness, evil, disrespect and hate.

ECO-STUDIES

Academically, numerous overlapping kinds of eco-studies may be perceived; we refer explicitly to five kinds here. The prefix eco-(from the Greek *oikos*, home as an edifice with its inhabitants) relates to a generic home-like phenomenon in which a living entity interacts with its living and non-living environment, which may include an artificial dwelling place. This approach parallels the combined

consideration of text and context by some scholars with a focus on information.

A living entity may have living sub-entities within it. It follows from this basic perception that study of an eco-phenomenon transcends any conceptual dichotomy between analytical reductionism and observational or intuitive holism. Neither the reductionistic nor the holistic approach is wrong; instead each is just half-baked. Sometimes the eco-approach is termed *holonistic*, with the *hol* referring to whole, and the *on*, referring to part and this makes explicit the transcendence of the reductionism–holism debate.

The versions of eco-studies include:

1. *Eciatrics* (from *eco* and *iatros* as pertaining to physician or medicine) includes public health studies of humans and domestic animals with respect to effects of pathogens on organisms and populations, as in epidemiology, and risk assessment studies of effects of toxins and contaminants on the organismal and population health of humans and other species.
2. *Ecology* or *ecologics* (from *eco* and *logos* as pertaining to reasoned knowledge) here narrowly defined and including interactive aspects of meteorology, hydrology, geology as well as conventional biology, and relating to the contemporary real time processes of biological evolution.
3. *Economics* (from *eco* and *nomos* as pertaining to law or laws) in which the practices of benefit–cost accounting and monetary risk assessment may be of minor significance overall compared, say, to an understanding of the self-organizing features of local sharing of ecosystemic goods/bads and services/disservices in a communitarian regime, and/or to global trade within a constrained free enterprise regime.
4. *Ekistics* (from *oikizo* meaning the establishment of a settlement) relating to the self-organizational development of human urban and rural settlements, physical infrastructures, industrial complexes, the information highway, etc.
5. *Ecumenics* (from *oikoumenos* meaning all beings in community) here with a focus on participatory governance within an extended community of interest groups or stakeholders, and including informal, extra-constitutional decision-making structures and processes that transcend boundaries between people of different nations and jurisdictions and thus complement the formal, constitutional laws, treaties and agreements of autonomous nations, as those were once perceived.

To study living systems, the psychologist and game theorist Rapoport (1986) has emphasized identity, organization and goal directedness. In a compatible way, the writer Koestler (1969) focused on self-organization, hierarchy and openness. Koestler excluded some connotations of hierarchy, e.g., the control hierarchy within a large military unit. Instead he referred to reciprocal nested interactions among *holons*, i.e., things that act as wholes but also as parts of larger wholes, within a form of organization that may be termed a *holonarchy*. A well-known example of a loose holonarchy is the interactive complex of nested formal and informal organizations within a multi-tiered form of liberal democratic governance, as may be described in ecumenics.

The conceptual domain that includes the five nested versions of eco-studies sketched above, plus some others, may be termed an *ecogeny*. The suffix refers to genesis, which refers here to emergent self-creation guided in part by *a priori* genetic hardware as well as by learned software, both augmented by new autonomous programming. Cooperative study by colleagues and ourselves in the North American Great Lakes Basin, for example, makes use of all those versions of eco-studies within an ecosystem approach that may be perceived as a special case of integrated ecogenic studies. Haas (1999) might refer to our self-organizing study group as a kind of epistemic community and we might refer to ourselves more specifically as an eco-epistemic community.

Here *epistemic* relates to a compendium of shared perspective and knowledge that is offered as having particular relevance to a major cultural challenge or opportunity. Some scholars may relate this epistemic concept to that of an expanded version of what Thomas Kuhn referred to as a scientific paradigm (see Fuller, 2000). Incidentally, we have chosen not to include an explicit notion of paradigm shift, but note that our version of that notion is implicit throughout. In other words, what we here define as *ecogeny* has flipped from being a suppressed theme within modernism to become a key theme within post-modernism.

Many non-living as well as ecogenic systems can exist in more than one phase, state or topological domain of attraction as the ecologist C S Holling has long emphasized. After being harangued by Holling for many years to provide him with Great Lakes data that would demonstrate ecological phase shifts, one of us, Regier, finally asked himself the question: If phase shifts have occurred, where and how could we look for evidence of such events? He decided to search for limits to the adaptive self-organization of a fish association (considered as a holon) to an array of intensifying stresses by humans in the larger environmental holon, and then examine whether another phase self-organized beyond a limit or threshold. Sure enough, the evidence was there, though it may not have been fully consistent with Holling's expectations. (See section titled Benthic and Pelagic Attractors in Ecosystems for more information on this issue.)

Researchers on natural and cultural systems once used single phase, deterministic, cybernetic systems as models. Any phase shift was then perceived as a catastrophic failure of pre-programmed cybernetic adaptiveness. Researchers

now perceive natural/cultural systems to be self-organizing and *morphogenetic*, and some phase shifts are just part of the adaptive, emergent capability of the evolving system. (Here morphogenetic implies that the forms or structures as morphs as well as the related processes of living things emerge through self-organizational genesis.) The death of a living system is an ultimate kind of phase shift when all adaptive capabilities are over-ridden, because the stresses either are too intense or act too rapidly.

When ecogenic realities are changing rapidly, as is now the case in many parts of the biosphere, one might expect adaptive and emergent phase shifts to be common, and catastrophic shifts all the way to systemic death to occur as well.

Selected examples are sketched below to demonstrate that phase shift events now occur ubiquitously. We note again that phase shifts may be referred to as flip-flops between organizational states as in discussion of major back and forth changes in the earth's climate that have seemingly occurred suddenly in the past. We start with non-living systems, then turn to living systems in which cultural features are not emphasized, and then to living systems in which cultural features are emphasized. But we do not address unnatural things like any divine acts of deities or things for which no empirical data are conceivable.

EXAMPLES OF PHASES AND PHASE SHIFTS IN BIOPHYSICAL SYSTEMS

Different Phases of Water

Everyone knows that water can occur in different phases, e.g., liquid, solid and gas. When some research physicists focused on phase shift phenomena with water, their model implied the existence of a fourth phase, under special circumstances. They called it the *gaquid* phase and found that it materialized under the expected artificial combination of temperature and pressure.

When a liquid water system cools through 0 °C it freezes to become a solid water system. The detailed features of the freezing process are anything but deterministic in a simple way, when viewed at a molecular scale. In nature, it is generally not possible to predict either precisely how and when liquid water will freeze during a cooling regime or the crystalline form of ice that results.

The freezing phenomenon itself is of major importance to those aquatic living things which have to find some way to adapt anatomically and/or physiologically and/or behaviorally to freezing. Such adaptations in turn may be perceived to involve phase shifts in anatomy and/or physiology and/or behavior.

At a more macroscopic level, the kind of ice that forms in a stream is important ecologically. Anchor ice, frazzle ice and surface ice have quite different implications for brook trout, for example. From an ecological perspective, each of these involves a different kind of phase shift from liquid to solid.

Different Phases of Flow Dynamics

When water flows at low velocities across a smooth surface, it may move as a sheet with laminar flow; at higher velocities it may flow in complex turbulent swirls. Turbulent flow in turn may occur as a number of different sub-phases. Researchers in fluid dynamics have focused much scientific attention on: what determines which phase of flow regime will occur in a particular context; the macroscopic features of the threshold between the phases; and the more microscopic details of the phase shift process itself. Their understanding, condensed in the form of a Reynolds Number, allows them to predict quite accurately a phase shift between turbulent and laminar flow within a pure liquid. The more particles or lumps in the system, the less accurate any forecast based on such a pure system Reynolds Number will be.

The issue of phases and phase shifts in the flow regime is of key importance to aquatic organisms. While migrating, for example, salmon may use a standing wave in turbulent flow to catapult themselves over an obstruction in a river. To rest, a fish may select a site of laminar flow downstream from an obstruction and adjust its fins so that it rests lightly on the bottom.

One dramatic example of such phase shifts in fluids is the well-defined transition from conductive to convective heat transfer. If a fluid is contained between a hot and a cold boundary, heat transfer will occur through the fluid. Consider thin soup in a pot on a stove as an example. For small temperature differences between the surfaces, the heat transfer is by random molecular motion, *conduction*. However as the temperature increases, a critical point is reached at which a new phase emerges, convection. With convection the fluid molecules self-organize to move together in rolls or Benard cells as coherent wholes. As the temperature difference between hot and cold boundaries increases, the original configuration of Benard cells may self-organize into a more complex configuration. With each phase shift, more heat is transferred, per unit time, than in the previous phase.

At a human scale, avoiding the phase shift from conduction to convection is at the heart of the design of double pane and triple pane windows. These windows are designed so that convective heat transfer cannot emerge, thus limiting the heat loss through the window to that of conduction.

At a regional scale, on clear summer days with a particular kind of atmospheric stratification, the Sun's warming of the land surface leads to warming of the overlying air. Bubbles of such warm air of decreased density may then form spontaneously and episodically to rise and erupt into

an overlying cooler layer; these bubbles of warm clear air may transform into cumulus clouds within the cooler layer. In particular locales, successive fluffy clouds that emerge may be evenly spaced in the drifting upper layer.

At the global scale, the emergence of large *convection* cells in the atmosphere, called Hadley cells (*see* **Hadley Circulation**, Volume 1), helps to transfer heat from the equator to the pole, thus reducing north-south temperature differences between the equator and the poles.

Many kinds of phase shifts may occur within the hydrosphere and the atmosphere, since these spheres consist of fluid components with different properties acting and interacting across boundary layers under the influence of solar radiation.

Flows in Water Courses and Flood Plains

Rivers carve water courses or channels out of the substrate to accommodate their flows during most days of a year, but not during high flow rates when flooding occurs. It is important to note that the course that a river cuts through a landscape is usually not large enough to include the flows of normal annual floods. The area known as the floodplain and its valley in turn have also been created, at least in part, by the continually shifting meandering river course, and especially by its floods. Hydrologists do not fully understand why a river self-organizes as a biphasal phenomenon, with one phase for small to moderate flows, and another phase for large flows. But hydrologists have inferred generalizations about the channels and flood plains of particular aquatic systems that have adapted over long periods of time to the underlying geology, under the influence of climatic regimes that have operated in quite predictable ways.

A river channel, flood plain and the larger valley are always dynamic; they may approach a steady state under conditions like those sketched above, but they are never in equilibrium with their surroundings. For example, a river never stops dissolving and eroding its substrates and walls. Living organisms, especially large plants and animals that eat the plants that live within and beside a river, strongly influence the self-organizing hydrological activities and usually have a taming influence on the waters, to the advantage of the organisms.

Cultural practices in a watershed strongly modify the temporal and spatial features of the natural flooding regime, e.g., by putting a river into an engineered channel, or by cutting down forests farther upstream. In effect a flooding phase shift occurs more frequently during a year if the watershed becomes ecologically degraded or is developed inappropriately, and the river has not had enough decades to adapt to those changes. Thus conventional unsustainable development has led to more frequent and more rapid phase shifts of the flow regime, and thus to more frequent and intense periods of turbulent stress for the living system of a river. Such a river may be perceived to be angry and may not approximate benign steady-state conditions at any time of year.

Phenology and Seasonal Phase Shifts

In temperate regions as in the Great Lakes Basin, the annual cycle involves a spring and summer phase that is dominated trophically by composers that use the sunlight's energy for photosynthesis, e.g., plants, and a fall and winter phase dominated by decomposers that use the energy of organic matter derived from photosynthesis and stored in summer, e.g., animals and fungi. Each of these phases and their transitions are intricately choreographed in what could be called a pristine, *old growth* state of the Basin ecosystem. The term is extended here beyond its familiar use as in old growth forest, to mean any ecosystem that has evolved its own complexity under benign conditions over extensive periods of time. Unsustainable development disrupts the natural self-organizing processes, so that the sequential features within phases and particularly during the phase shifts become less predictable, from the perspective of the extant species.

In warmer regions, the climate may include a wet season and a dry season. Cyclical changes, somewhat similar to those sketched above occur here, too.

Benthic and Pelagic Attractors in Ecosystems

Moderately deep natural aquatic ecosystems that are not much influenced by technologically careless humans usually have clear waters and a biotic association or benthos that is linked strongly to the bottom of the waters. In effect a benthic attractor or self-organizing system then emerges to serve its own ends, for example by preying on the open water association or *pelagos* to keep the water above it transparent and by hoarding phosphates and other nutrients that deprive pelagic organisms of these resources. Ecologically, the benthic association has similarities to the old growth state of primeval forests or grasslands. There are long-lived, large, sessile or sedentary plants, invertebrates and vertebrates with some of the latter migrating annually in stereotyped patterns. The dominant species of the benthos may be termed K-selected (see Box 1).

Unfortunately it happens that nearly all the cultural stresses imposed by humans act to impair and incapacitate such a benthic attractor. Near the surface in moderately deep waters, a pelagic attractor, mostly with r-selected species (see Box 1), may then self-organize because ample nutrients then occur in those waters. A burgeoning pelagic association may then act so as to further suppress the benthic attractor already harmed by unsustainable cultural practices. This is a case of positive feedback, which occurs

Box 1 The meanings of the r and K terms

The r and K symbols originated in a particular formula for the physical growth of an organism, but have taken on a metaphorical life of their own in discussions of species successions as related to phase shifts. In an early successional stage, as in a cultivated field that is reverting to nature or with the herbaceous vegetation in a temperate forest in spring, r species that are small, short-lived, fast growing, early maturing and tolerant of fluctuating environmental conditions generally thrive and reproduce first. These are gradually replaced in late spring by activation of K species that are large, long-lived, slow growing, late maturing and intolerant of fluctuating environmental conditions. Within phase changes, the switch from dominance by one type to dominance by another is generally not complete (*see* **r–K Strategies**, Volume 2).

commonly in an early stage of the self-organization of a phase of a living system. With further organization, negative feedbacks are generated within the evolving new phase to counter-balance the positive feedbacks, or even to exceed the positive feedbacks, as in some over-mature senile, or old growth manifestation of a phase in an ecosystem.

The terms *oligotrophic* (few food items) and *eutrophic* (many food items) are commonly used to denote aquatic systems in which benthic and pelagic attractors, respectively, are dominant. These may be taken to be code words, since much more than trophic status is involved in oligotrophic type and eutrophic type systems.

In Regier and Kay (1996) and Kay and Regier (1999), we have focused attention on the kind of phase shifts between states that are dominated by the benthic and the pelagic attractors in the three basins of Lake Erie. Other researchers are taking a comparable approach to shallow or *lentic* waters of coastal wetlands and deeper or *lotic* waters as in rift lakes.

With respect to the whole gamut of aquatic ecosystems, there may be more kinds of attractors, and related phase shifts. One such state, that of a *saprobien system*, is particularly objectionable to humans in warmer parts of the world. European researchers who studied the effects of sewage outfalls on rivers starting a century ago first described a saprobien system. Just downstream from an outfall, sewage decomposes aerobically and this process may quickly exhaust the oxygen in the water. With farther movement downstream, the aerobic organisms die and anaerobic organisms become dominant. Ecological production by anaerobes may generate foul smelling gases based on reduced forms of sulfur, carbon and nitrogen, as also is the case with poorly managed cesspools. Farther downstream, the demand for oxygen by the biota can be met by the slow diffusion of oxygen from the atmosphere into the water, and this marks the downstream boundary of the saprobien system.

The saprobien system bears some resemblance to the decomposer association that forms on the bottom of strongly eutrophic lake waters of moderate depth.

Excessive enrichment of waters with plant nutrients may cause more severe eutrophication as hypertrophy. In relatively quiescent waters there may then emerge a surface association with floating and decomposing mats of algae, fungus, slimes and bacteria together with blooms of toxic algae where the matting is not continuous.

Caddy (1993) has observed ecological phenomena in enclosed and semi-enclosed seas subjected to unsustainable development that are similar to the phase shifts that we and others have inferred for freshwaters.

FROM GREY–BROWN TO GREEN–BLUE TECHNOLOGY

In the past, hydrological engineers were expected to correct the destructive behavior of streams that were excessively turbulent because of abuse upon abuse to which these streams and their watersheds had been subjected. Though the ecological causes of the destructiveness of an abused stream were understood in the mid-19th century by George Perkins Marsh (*see* Marsh, George Perkins, Volume 3) and others, there was not then an adequate planning or regulatory capability (see following section) to correct enough of these abuses at their sources to permit the stream to recover its gentler features. So the engineers resorted to dealing with local effects where some crisis had erupted, often by creating an ugly new water course with concrete and steel and enclosing it with tall fencing because people who fell into raging waters in such a channel were likely to drown. This concrete and steel *grey- brown technology* exacerbated the turbulent adverse effects downstream, which then called for more concrete and steel with more muddy water, etc. This is an example of positive feedback within anti-ecological technology.

A phase shift in planning and management of such human-altered streams occurred when the governance processes switched so that a watershed ecosystem approach came to use nature's way; *green- blue technology*. This phase shift involves compatible phase changes in the disciplines of engineering, of planning and in the expectations of affected residents. Such a comprehensive phase shift might be resisted by a government administration committed to encouraging the production and sale of concrete and steel, say, and to providing remunerative contracts for conventional engineering and construction firms. Government patronage, with the help of grey–brown bureaucrats, has long funded ecosystemically abusive engineering works related to harbors and streams. The institutional connections between a government agency, an industry and the relevant profession or interactive set of professions that led to such

autocatalysis or positive feedback has been referred to as an *iron triangle* in the US.

With streams of the Great Lakes Basin, we appear to be in the throes of a phase shift toward an ecosystem/watershed/landscape approach, i.e., to green–blue technology.

A CRUCIAL CULTURAL PHASE SHIFT AT A GLOBAL LEVEL

As has become increasingly obvious in many United Nations (UN) conferences since 1970, a crucial policy initiative on food, environment, population and development anywhere in the world has been to facilitate the self-empowerment of women (*see* Ecofeminism, Volume 5). Eco-feminists can explain much better than we can the necessity for a cultural phase shift toward a status for women that they prefer and must have. This involves a systemic change in the status of men, or at least of some men. According to women leaders of this movement, such a phase shift should not be a zero-sum game, in that few women want to compete directly with men to the disadvantage of men. Instead the shift should move from a culturally impoverished state of male dominance to a richer and better state of cross gender partnership.

At the UN Conference on Population and Development in Cairo in 1994, for example, strong resistance to such a phase shift came from male clergy who propounded narrow, fundamentalistic versions of the Judeo–Christian–Muslim family of religions. Though they may raise important ethical issues, such clerics and their male followers may not be disinterested personally since they may lose status and power with such a shift. Many men who are not constrained by these fundamentalisms are making common cause with self-empowering women.

What are some of the implications of a gender-related phase shift for Great Lakes Basin ecosystems, say? The phase shift from the grey–brown to green–blue technology sketched above may well be due in part to the increased participation in recent decades by women in all aspects of research, planning and management related to those streams.

Twenty years ago one of us, Regier, supervised the thesis research on the fish of the Credit River (near Toronto) by Deborah Martin, now Deborah Martin-Downs (Martin, 1984). She had learned to identify all fish in all life stages so that it would seldom be necessary to kill and preserve specimens. So she had data but few specimens, and sometimes could not respond in the usual way to a query whether she really had seen a specimen of a particular species at a particular locale. Though there were raised eyebrows and some testy queries during her oral examination, nobody considered the absence of dead specimens as a serious weakness of her method, and all respected her ethics. Such ethics may require that high expertise in recognizing fish species in the field be demonstrated for skeptical colleagues.

In the Great Lakes Basin since the 1950s, some, and perhaps most of the key environmental victories have been won with leadership by women. Many of the women were unpaid volunteers or underpaid activists. Mostly it has been well paid men who then led with the implementation.

Men should participate in correcting the degradation now so obvious in ecosystems everywhere. Of course, there were always individual men who were not part of the degrading culture. Similarly there were women who were willingly part of it, and may occasionally have been leaders of the degrading progressive modernism (*see also* Ecofeminism, Volume 5).

INDIGENOUS PEOPLES AND CORRECTION OF AN EARLIER PHASE SHIFT

In the UN conferences of the 1970s (on food in 1970, on the environment in 1972 and on population in 1974), some attention was focused on the injustices directed toward indigenous peoples as a consequence of invasions of their lands and waters by modern progressives. This theme became much more pronounced in the 1990s UN conferences on the environment and development, population and women. Agenda 21, issued by the 1992 UN Conference on Environment and Development in Rio de Janeiro, has a strong section on indigenous peoples.

With respect to Great Lakes Basin waters, aboriginals' non-ceded rights are coming to be recognized again, very belatedly. Since many aboriginals, both women and men, are re-committing themselves and their people to nature stewardship, this process of re-empowerment should be welcomed.

As with empowerment of women, re-empowerment of indigenous peoples should enrich our impoverished culture. Tolerance of diverse cultures may be as desirable as biodiversity. The phase shift toward fair status for indigenous or native peoples is not yet assured in the Great Lakes Basin generally, or elsewhere in the world. Non-native guardians of these waters are committed to partnerships with the native guardians (*see also* Indigenous Knowledge, Peoples and Sustainable Practice, Volume 5; Religion and Environment Among North American First Nations, Volume 5).

FROM MODERNISM THROUGH POST-MODERNISM TO WHAT?

Some thirty years ago the Western World apparently passed beyond the centuries-long era of modern progress, in a massive cultural phase shift that is still underway. The management guru, Drucker (1989) has sketched this shift in

ways that many would consider brash, but after publishing widely acknowledged seminal works for over 50 years; some continuing brashness from Drucker may be tolerable. Drucker's ecological perspective on all of this emerged out of the new discipline of business administration, and is similar to what we refer to here as *ecogenic*.

One of us, Regier (1995), has listed some 15 transitional phenomena that occurred in or about 1968, at about the time inferred by Drucker to be the height of land between the conceptual basin of the modern era and the conceptual basin of the new era. The latter era is still apparently nameless; though some people refer to it as *post-industrial* or *post-modern*.

Stronger commitments to *deontological* ethics (ethics based on a deep shared sense of what is right and what is wrong with respect to duty) may increasingly be trumping modernist commitments to utilitarian ethics; ethics based on the greatest good for the greatest number. Integrity may be a code word for such a deontological commitment. In the 1960s social integration, toward a new and desirable cultural integrity, was directed toward correcting racial and gender inequities in Western countries. Since then, integration of many indigenous peoples into emerging political systems has been leading toward a mosaic landscape integrity that is apparent politically, culturally and ecologically, from an ecogenic perspective.

Agenda 21, that outcome of the 1992 UN Conference on Environment and Development in Rio, includes deontological as well as utilitarian commitments to global programs of several kinds, e.g., to preserve biodiversity. Thus a deontological commitment to biodiversity concerning Great Lakes Basin waters links to a compatible global commitment. Such connections should be recognized and be supported by strong institutional links, as has been attempted at the federal Canadian level. Local stream stewards, say, could draw encouragement from the sense that they are necessary parts of a global ethical commitment to ecological integrity.

CONCLUSIONS

Nine kinds of systemic phase shifts have been sketched above, all in a conceptual context of dynamic self-organizing ecogenic systems. We hope that this evidence suffices to make the point that such phase shifts are now ubiquitous in all the five versions of eco-studies to which we have referred here. If so, our educational, research, practice and governance initiatives should more clearly reflect that awareness.

Practically, a precautionary principle invoked in the context of a commitment to sustainable and responsible use implies that informed judgement be exercised to avert phase shifts to undesirable states. Once a phase shift has occurred, efforts to reverse the shift may be very costly and take much time because of the effects of systemic inertia or hysteresis.

There is, as yet, no strong empirical evidence to support optimism about the 21st Century. The new era, following the cultural phase shift sketched above, may play out worse than the progressive modern era that is now behind us. For example, it may turn out that our environmental and cultural reforms will have been too little and too late; and we humans may trigger flips into a succession of less desirable states of kinds that we have not yet encountered. Ecogenically there may then be no way back to something resembling an earlier manifestation of our biospheric home.

Political Movements/ Ideologies and the Environment

David Pepper
Oxford Brookes University, Oxford, UK

There is no one, politically uniform, environmental movement in the West, but a series of movements and groups. They represent a massive growth in popular concern about the negative ecological consequences of economic and technological development since the 1960s. Initial worries, like those over the impact of agricultural chemicals on the environment, soon broadened to include all pollution caused by economic and technological development, and the issue of population growth, consumerism and resource use. This developed into a challenge to the whole notion of 'progress' implied in Western development since the Enlightenment, and to industrial society and its view of social justice.

After some early impact on policy in the 1970s, there was a period of retrenchment from environmental legislation in the 1980s by Western governments. They were in uenced by the arguments of business and industry, which in a climate of increasing global competitiveness saw environmental and social spending as brakes on ef ciency and pro ts. While this climate still prevails, the of cial stance of governments since the 1992 Rio Conference has been that the interests of pro table business and environmental protection are compatible. Hence environmental sustainability principles are supposed to be incorporated into all main policy areas under the development model known as ecological modernization.

Environmental movements have reacted to these trends by developing political parties, pressure groups and other approaches. These have sought to in uence government from the outside via public opinion, and also to become part of policy formulation from the inside. In the 1990s there has also been a revival of direct action, which sometimes breaks the law, by environmentalist factions who are disillusioned with the democratic processes.

Two approaches to environmental politics have developed. Reformism seeks to change society substantially to achieve environmentally sustainable development, but not to the extent of abandoning capitalism and the modern scienti c, technological and managerial expertise on which mainstream development is based. Radical environmentalism, however, does ultimately wish to radically change or remove capitalism, replacing it with forms of localized development that prioritize social need, direct grass-roots democracy, and environmental protection rather than economic and technological growth.

Mainstream environmentalist political ideology, therefore, re ects these currents, drawing on radical and reformist political traditions going back at least as far as the 18th century. Reformism re ects conservative, liberal and democratic socialist traditions. Environmental radicalism is especially in uenced by anarchist and revolutionary socialist traditions, mingled in with some conservative thinking. The result is a very mixed and sometimes incoherent ideology, whose underlying current re ects either an 'ecocentric' approach which prioritizes the needs of natural ecosystems, or a human-centered (anthropocentric) approach which prioritizes human social, economic and cultural considerations. The fact that mainstream environmentalism

re ects all these in uences and cross-currents could be seen strategically as both a strength and a weakness.

THE ENVIRONMENTAL MOVEMENT'S ORIGINS AND CONCERNS

Everyday political discourse now frequently refers to *the* environmental movement, a late twentieth-century manifestation of widespread concern in the West about the negative ecological consequences of economic and technological development. Strictly speaking such references are only partly accurate. First, there is no one, coherent environmental movement, as much of the rest of this entry will con rm. Rather, there is a whole complex of movements and ideologies, within and outside conventional politics, expressing environmental concern and proposing social and political solutions for it.

Secondly, environmental movements did not originate in the late 20th century; they are rooted in earlier movements. In America, the 19th century wilderness preservation movement, inspired by John Muir, Henry David Thoreau and Ralph Waldo Emerson, gave rise to the Sierra Club, from which in 1969 a group of more radical conservationists splintered to produce Friends of the Earth. In Europe, the National Trust, one of the UK s major contemporary environmental preservation groups, was founded in 1895. The founding group was inspired by challenging, questioning attitudes towards industrialism and progress posed by people such as John Ruskin and William Morris: it also drew on feelings for natural landscape inspired by Romantic gures such as William Wordsworth. Other direct in uences on today s environmentalism include the development of the science of ecology, whose leading gures included 18th and 19th century naturalists such as Gilbert White, Charles Lyell, Charles Darwin and Ernst Haeckel. The work done on population by Thomas Malthus is also directly re ected in the modern movement, as is the in uence of 19th and early 20th century anarchists and utopian socialists (*see* **Political Systems and the Environment: Utopianism**, Volume 5).

Furthermore, in between the World Wars there were vigorous movements in the West showing concern for nature and for healthy lifestyles, including vegetarianism. These were intertwined with both left and right-wing (including fascist) political movements, among both the masses and intellectuals (for a description of the roots of the environmental movement, see Pepper, 1996).

However, it is true to say that environmental movements, which started to emerge in the 1960s, have shown greater scope, range and connectivity than any previous environmental movement. This was inevitable, given: (a) the global advance of modernizing societies and economies: (b) the development of instantaneous and ubiquitous global communications networks: and (c) the unprecedented power of post-war technologies to create alarming environmental changes. As sociologists Ulrich Beck and Anthony Giddens emphasize, today s society is exposed to unprecedented risks and uncertainties, whose origins it is often dif cult to unravel, determine and control (Beck, 1992, 1995). These include environmental risks of (particularly Western) society s own making.

The rst of these to trigger widespread alarm, marking the dawn of modern environmentalism, was that caused by the chemical substances used in agriculture. They were identi ed in Rachel Carson s iconoclastic work, *Silent Spring* (1962) (*see* **Carson, Rachel Louise**, Volume 5). Before this book, American and European conventional wisdom held that chemical pesticides and herbicides were an unalloyed blessing: helping developed countries under capitalism to repel Malthusian spectres of famine and want, and build that steadily-advancing material prosperity on which the American Dream and post-war European recovery were based. The questioning, sparked by Carson s book, of this conventional wisdom, and the subsequent wave of popular skepticism about scienti c advances, technological experts and the motives of big corporations, fed into what is now described as a condition of *post-modernity* , which some see as the prevailing mode in Western thought.

In it, all those things enshrined in the notion of progress adopted since the Enlightenment have been questioned and often denounced. Of course, there always was a critical, counter-cultural minority current in the West accompanying industrial and democratic revolutions, and its 1960s expressions in the hippie, civil rights, anti-nuclear and feminist movements fed directly into the environmental movement. Many sociologists see all these together as a coherent wave of new social movements forming the basis of post-modern politics. New social movements are inspired by single issues, but they also express the unease, disillusionment and aspirations of the newly emerged (professional, especially) middle-classes. Some commentators think that as such, they have supplanted the old basis of political discourse, in worker-capitalist relations and struggles over distributing material wealth.

The concern with pesticides soon widened to embrace all environmental pollution caused by modern technologies, including nuclear power and weapons, and then in the 1980s and 1990s, the internal combustion engine, gene modi cation, factory farming and the like. In the late 1960s and 1970s, too, there was growing questioning of mass production and mass consumption, combined with a wave of near-hysteria about human population growth, particularly growth in the third world. Thus emerged the neo-Malthusian limits to growth school (Meadows *et al.*, 1972, 1992; Hardin, 1968, 1974; Ehrlich, 1969; Ehrlich and Ehrlich, 1990). This contradicted the widely held views that materially based economic growth could continue *ad infinitum*, and that levels of af uence enjoyed in the West could be attained by all the world s population (which

appeared to be increasing exponentially). Limits to such growth were imposed by earth's carrying capacity – by constraints such as the inability of eco-systems to provide enough resources to feed growth or to soak up the pollution associated with it.

Based on such arguments, early environmental movements successfully prevailed on American and European governments to legislate tighter environmental standards in the 1970s, and to set up agencies and procedures designed to protect the environment. In America, particularly, groups mounted successful legal challenges to development likely to endanger animal and plant species survival, grounding them in an eco-centric' philosophy which said that nature has intrinsic value: value beyond its usefulness to humans. This was all done in a prevailing political-economic climate where the legitimacy of state spending and market intervention to mitigate the worst social effects of the free market was upheld by a significant majority of politicians. Hence, if business and industry now had to spend some potential profits on procedures, processes and technologies to protect the environment, this was regarded as proper and necessary.

However in the 1980s and 1990s, in the face of intensifying global competition and pressures on profit margins, the philosophy of economic *laissez-faire* took on new political vitality. Neo-liberal governments in North America, Australia and Europe began anew to prioritize economic growth and to side with industry in regarding regulations and tax-funded public spending on high levels of social and environmental protection as undesirable business overhead costs which must be reduced. Consequently a retrenchment phase began, with relaxation of regulation, and downward pressures on environmental protection spending. Although officially such attitudes have now changed, their momentum persists in anti-environmentalism, where, for instance, some business corporations form unofficial coalitions (e.g., the European Round Table or the Global Climate Coalition) specifically to lobby against pressures from environmental lobbies. They challenge, for instance, the validity of scientific research which suggests that human-induced global warming is significantly increasing.

At the same time, the 1990s saw a new phase where environmentalist concerns seem to have been taken on board by mainstream politics. Nearly all of the world's governments were officially represented at the 1992 United Nations Conference on Environment and Development; the Rio Conference'. And very many of them signed that conference's declarations, amounting to broad and unspecified commitment to the notion that environmental protection must be integrated into the mission of universalizing material prosperity – a mission still to be achieved, however, through global marketization and the search for economic growth. Hence the idea of materially-led universal development was not abandoned, but the caveat was added that it must be sustainable, meaning that the resources needed for it should not be destroyed, and the options open to future generations to live at least as well as the present one should not be foreclosed. The development model, which is supposed to enable this is that of *ecological modernization* (*see* Political Systems and the Environment: Utopianism, Volume 5). During this phase of environmental concern, sustainability objectives have been written into mainstream policy programs of the leading industrial nations, intending that they should be integrated within economic and social objectives. This clearly means that the limits to growth school's major premise, of incompatibility between growth and environmental protection, has been rejected in favor of its obverse – the idea that the two are necessary to each other.

As these phases of environmental concern have progressed, the emphases in the mainstream of environmental movements have altered. The initial focus was on single issues, but quickly this developed into the skeptical questioning, mentioned above, of industrialism and modernity. This put environmental pressure groups generally at odds with the establishment and the political mainstream. Through the 1980s, however, they began to acquire more influence, augmented by electoral success in some European countries. During and after the Rio Conference, some groups (e.g., Friends of the Earth) gained semi-official status as non-government organizations (NGO). As such, they make formal presentations to the UN Commission for Sustainable Development, and in some cases are incorporated onto the panels of local Agenda 21 organizations set up in towns and cities in the wake of Rio.

At the same time as environmental groups have developed their expertise and mainstream influence, their underlying analyses of causes and effects of environmental problems have often become more sophisticated. They are more likely to highlight problems like the internal growth dynamic of capitalism and its inherent tendency to take only partial and short-term perspectives on problems, the apparently unavoidably uneven nature of development as global modernization, the inextricable connection between environmental problems and social inequity and injustice and the way in which Western affluent lifestyles leave substantial ecological footprints in third-world countries (e.g., toxic waste produced in the West being shipped to the third world for dumping or processing). The overall political direction of such a critique may point towards radical social change, beyond that envisaged in even strong' approaches to ecological modernization. This has uncomfortable implications for Western mainstream politics.

Hence, late-1990s environmental movements followed two paths. Some groups, or factions within groups, persisted along the channels of conventional political action, such as running for office, lobbying and advising government and other bodies. Other groups and factions began a new wave of direct action (both peaceful and violent) and civil disobedience, intending to block developments

such as the growth of road traffic into residential areas, the building of new roads, nuclear waste dumping, trials of genetically-modified crops, or foxhunting and other animal abuse. In some of these protests, notably over major road development at Twyford Down and Newbury in the UK, such eco-anarchist protestors have been supported by many middle-class citizens living conventional lifestyles. The former have been concerned about general environmental and social principles, while the latter have been representing their own limited, local interests (the NIMBY – not-in-my-back-yard syndrome). What unites these unlikely bedfellows is (a) shared concern about quality-of-life issues, including environmental quality (b) deepening conviction that commitment to profitable, efficient, competitive business should not be prioritized above all other social-economic policy considerations (c) increasing skepticism and frustration with Western democracy, on the grounds that it is more responsive to the needs of international business lobbies than to those of the ordinary citizen. This last concern is responded to in some areas of EU policy, for instance rural development, where resources are being put into developing bottom up', community-led initiatives. It is also reflected in the growing number of academic texts concerned with environmental democracy (e.g., Mason, 1999).

TYPES OF ENVIRONMENTAL MOVEMENT

Environmental movements includes green parties, pressure groups within mainstream political parties, non-party pressure groups, direct action groups, local community groups, communes and individuals exercising lifestyle choices. Connelly and Smith (1999) stress how the ethical underpinnings of these groups are extremely diverse and difficult to reconcile as one movement. They identify New Zealand as the location of the first green party, founded in 1972. The second was started in the UK in 1973, but the most prominent in electoral terms has been *Die Grünen*. This began from community groups in West Germany in 1980 and achieved government in coalition with social democrats in 1998. Electoral success appears to depend very much on the voting system adopted, hence UK Greens had 15% of the vote in the 1989 European Parliament elections but took no seats on the basis of a first-past-the-post system. In 1999 however, when proportional representation was adopted, the Greens took two seats from a much lower percentage vote.

However, the constant problems, which beset mainstream politicians of principle, have also dogged Green parties. In attaining and widening electoral support, or in actual government, principles have usually had to be compromised and this has opened internal splits between pragmatists, or realists', and fundamentalists. Such splits have been very public in Germany, leading to the resignation of leading Grunen members and the vilification of many who stayed, but they have been mirrored elsewhere. Ongoing internal debates and squabbles have occurred on such issues as the importance of obtaining office as opposed to the virtue of remaining a principled opposition, organization versus spontaneity, and the desirability or otherwise of playing the mainstream game involving party hierarchies, charismatic leaders, professionalism, media manipulation and public image. The UK Green Party suffered considerably in the early 1990s from such conflicts, and has not completely recovered. Meanwhile, in less than two years of government Die Grunen have compromised principles to the extent that internal critics fear that the most that has been achieved has been to help create a more viable capitalism; i.e., one which has been alerted to the dangers to itself arising from environmental problems.

These kinds of tensions mirror the dichotomy discussed below, between radical and reformist approaches to, and influences on, the environmental movement. Such tensions occur within groups and also within individuals. They result in what Dobson (1995) has identified as public and more private faces of radical environmentalism, where the desire for fundamental social change and the overturning of the economic order become deliberately muted themes in public debate for fear of frightening off ordinary members of the public.

Despite the limited electoral impact of Green parties, what seems an inexorable rise in public concern about environmental issues is illustrated through data cited by Connelly and Smith (1999) on eight UK environmental pressure groups. Their total membership rose from 1.5 m in 1980 to 4.3 m in 1995. Some of them, like the National Trust and Royal Society for the Protection of Birds, are long established and indisputably conservative and safe from the point of view of conventional political parties. Nonetheless, their growing strength has contributed to the greening of these parties. In the UK, Conservative, Liberal Democrat and Labour parties all have their own internal environmental pressure groups, and the amount of manifesto space devoted to environmental policy has steadily increased since the mid-1980s. But British politicians have been slow and recalcitrant in many environmental policy areas by comparison with politicians in Scandinavia, Germany and the Netherlands.

These latter countries have been at the forefront of projecting environmental policy within the EU, and as a result of some success here, Britain, once known as the dirty man of Europe', has been drawn into a more enlightened approach. This raises an interesting geopolitical dilemma for the British environmental movement, since both radical and reformist wings' tend to champion the idea of government decentralization and more inclusive local democracies. Large-scale economic, social or political structures are resisted in favor of localism and decision taking at the lowest possible level. But when this last principle, of

subsidiarity', has been applied by the European Union (UN) in relation to environmental matters it has sometimes enabled British governments to claim powers over their own development decisions, which have been unpopular with environmentalists. The latter have been driven to look to the supranational bureaucracy of the EU for protection from their own government.

Pressure groups do not seek electoral office, but, rather, hope to influence public policy. They act in support of a cause, rather than the narrower sectional interests of their members. Indeed there is an ongoing debate within Greenpeace about whether to have members at all, rather than just supporters. Pressure groups seek influence from inside government, through petitioning, lobbying and eventually being accepted as consultants during the stage of policy formulation. As a result, they attempt to make themselves credible by acquiring a reputation for painstaking scientific research of integrity, and for reasonableness', professionalism' and a willingness to dialogue and compromise with opposition groups. One such example in the UK is Transport 2000, a coalition of environmental groups concerned about transport issues, which have won government and public over to its view that private car use must be curbed in favor of public transport investment.

Pressure groups also seek to apply outside pressure on governments via public opinion. This requires a higher-profile approach, staging media events, demonstrations, petitions and consumer boycotts. Flamboyant media-grabbing tactics are often at the edges of the law, or involve breaking it before backing down in the glare of publicity, to disrupt, for instance, whale fishing, nuclear tests or public enquiries into development projects.

Hence pressure groups have to achieve a balance between two approaches, and this may be a source of ongoing internal disputes. Whether this balance swings towards or away from more conventional, respectable' and patient methods may well depend on the perception, which the group has about the nature of the democracy within which it works. If the belief is that this follows a pluralist model, in which many different interest groups have more or less equal opportunities to influence policy direction, then the group may concentrate on methods appropriate to this. If, however, the view is towards an elitist model, where some interests are seen as unfairly dominating the political process by virtue of their economic and political strength – often exercised in corridors of power – then less legal methods may be followed.

Direct action groups are of the latter persuasion. They include the likes of American Earth First! (Wall, 1999), with its monkeywrench' tactics of civil disobedience and ecotage' committed on the physical infrastructure of big development projects, such as dams. Then there are tree dwellers and tunnel diggers who have gained huge publicity in anti-road and anti-airport protest in Europe, North America and Japan. There are squatters, like those in The Land is Ours' group, who invaded derelict land owned by the Guinness Corporation and scheduled for major development in Wandsworth, London – they set up a model sustainable village for five months in 1996 before being evicted. And there are arsonists who set fire to agricultural developments and scientific establishments in the name of animal liberation. When challenged about why they do not use legal channels of protest and persuasion, they will reply that these channels are merely token, giving a veneer of democracy' to what is in fact a corporate state run by a coalition of bureaucrats, business leaders and, perhaps, union bosses.

Partly in response to this kind of critique, and partly as a result of budgetary cuts in local government spending, there has been a growth in the 1990s of local voluntary community-based groups. These seek, legally and often supported by government grants, to improve the economic prospects and social and environmental quality of life of their local community. They include such environmentally oriented groups as housing cooperatives, conservation and recycling projects, urban agriculture, box schemes' (where the produce of nearby organic farms is sold direct to households) and local employment and trading schemes (LETS, where goods and services are exchanged by means of local currencies). A skeptical view of such developments is that they help to exonerate the state-supported public sector from its duties to provide social, health and environmental care for all, which is why states generally have a favorable view of them. A more positive perspective is that they represent a process whereby people take their lives and destinies into their own hands, therefore reclaiming some political power.

This constitutes a major theme voiced with increasing urgency by environmentalists since the 1960s. They argue that if people regain control over their lives, and are re-embedded' into their communities and localities, it is axiomatic that they will behave in more environmentally sustainable ways. Through living more rounded and satisfying lifestyles, it is reckoned, people will not want to seek fulfillment in an endless round of material consumption. This is the basis on which ecologically based communes operate. The heyday of such alternative' communities was in the 1970s, when (especially) rural property and land were cheap to acquire. Back-to-the-land groups often resolved to achieve a large measure of self-sufficiency, in food if not energy, and to do it in ecologically benign ways. Although they usually failed in this objective for any sustained period, and although they encountered many problems in trying to create alternatives to the nuclear family and non-oppressive social relations, many of these communities have lasted into the 1990s. However, they have not remained immune to social trends in the mainstream society to which they form a counterculture, but have fallen prey to increasing materialism, privatization and

preoccupation with maintaining financial viability (Pepper, 1991). Notwithstanding this, they have contended with a set of problems which they prefer to the problems and insecurities of living in conventional society.

A further manifestation of environmentalism has been in the application of its personal-is-political' motif to consumerism itself. The green consumer movement peaked in the 1980s, but survived into the 1990s particularly as the ethical consumer and investor movements (*see* Green Investment, Volume 4). It is now part of the ecological modernization approach to development, and is based on the idea, championed by neo-liberal political economists like von Hayek in the 1950s, that in spending our personal money we are casting votes. These votes indicate desire for and satisfaction with the products we buy, and the processes and organizations through which they are produced. Hence, it is argued, if we buy ecologically sound' products and services, with environmentally sound ingredients produced in environmentally friendly ways, and if we shun products which do not meet this description, producers will have to change their ways accordingly or go out of business. Through this kind of consumer movement, chlorofluorocarbons (CFCs) have been eliminated from aerosols and refrigerators, real animal furs have been largely replaced by artificial ones, and, possibly, the development of foods containing genetically modified organisms has been arrested. Additionally there has been a big boost for organic food producers, tea and coffee producing cooperatives, and so forth.

However, the green consumer movement has not produced the widespread changes which were once claimed for it, and it has not defeated the skepticism of radical environmentalists. For one thing, its success depends on the presumptions that consumers have access to reliable and honest information about the products they buy, and are prepared to spend time and money acquiring and acting on such information. None of this has been proved accurate. Furthermore, the idea that money is a vote also carries the corollary that a large part of the potential electorate' is disbarred from voting by virtue of poverty, especially in times of recession. And in any case, the proposition that consumption of material goods is a remedy for environmental problems rather than being their major cause is still impossible to swallow for radical environmentalists.

POLITICAL IDEOLOGIES AND ENVIRONMENTALISM

Figure 1 shows different forms of environmentalism when considered particularly from the standpoint of political ideologies. It differentiates principally between radical and reformist approaches. The latter embrace mainstream culture's political ideologies of liberalism and democratic' (as practiced by labor and social democrat parties) socialism. It would reform capitalism and market economics to a greater or lesser degree, but would not replace them by another economic system. One of the main arguments within it is about *how much* to intervene in the market economy (see below). It reacts to environmental problems from a perspective which some call techno-centric'. Techno-centrism manifests faith in science, technology and rational management of ecosystems to solve environmental problems. Elements of conservative thinking also may mingle with this reformist approach of the cultural mainstream. Ecological modernization is the sustainable development model, which has evolved from reformist environmentalism.

By contrast, radical environmentalist approaches seek to eliminate environmental problems at their root, rather than simply reacting to the damage caused by the normal operations of global capitalism. This would entail fundamental social change, either by eliminating or completely reconstructing capitalism. Hence the environmental debate is shifted out of the cultural/economic mainstream and becomes counter-cultural: often drawing on older counter-cultural traditions such as anarchism or utopian socialism. It includes:

- *social ecology*, based largely on anarchist principles as interpreted particularly in the work of Murray Bookchin (e.g., 1990), which is also informed by Marxist analysis (*see* Social Ecology, Volume 5).
- *eco-socialism*, based on revolutionary rather than reformist (e.g., social democrat) socialism, and also informed by Marxist analysis. Libertarian, decentralist and communalist in principle, it is ultimately opposed to the state (*see* Eco-socialism, Volume 5).
- *deep ecology*, which focuses on fundamental changes in attitudes and values towards nature starting with the individual (Devall and Sessions, 1985). Its social prescriptions are anarchistic but also informed by elements of conservative thinking (*see* Deep Ecology, Volume 5).
- *ecofeminism*, which insists on the elimination of patriarchy as a prerequisite to founding a sustainable society. It is also informed by anarchist and socialist analyses of material processes in society, but emphasizes as well the importance of changes at the cultural level (*see* Ecofeminism, Volume 5).

Deep ecology's approach is eco- or bio-centric: that is, focused on non-human nature and the whole biosphere. Eco-centrism claims that nature has intrinsic value above and beyond the value merely conferred by humans. Eco-socialism, by contrast, shares an anthropocentric stance with reformist environmentalism. This regards humans as the ultimate source of all value and is prepared, if it comes to a crunch, to elevate human interest above that of animals and plants. Social ecology claims to transcend both anthropocentrism and biocentrism.

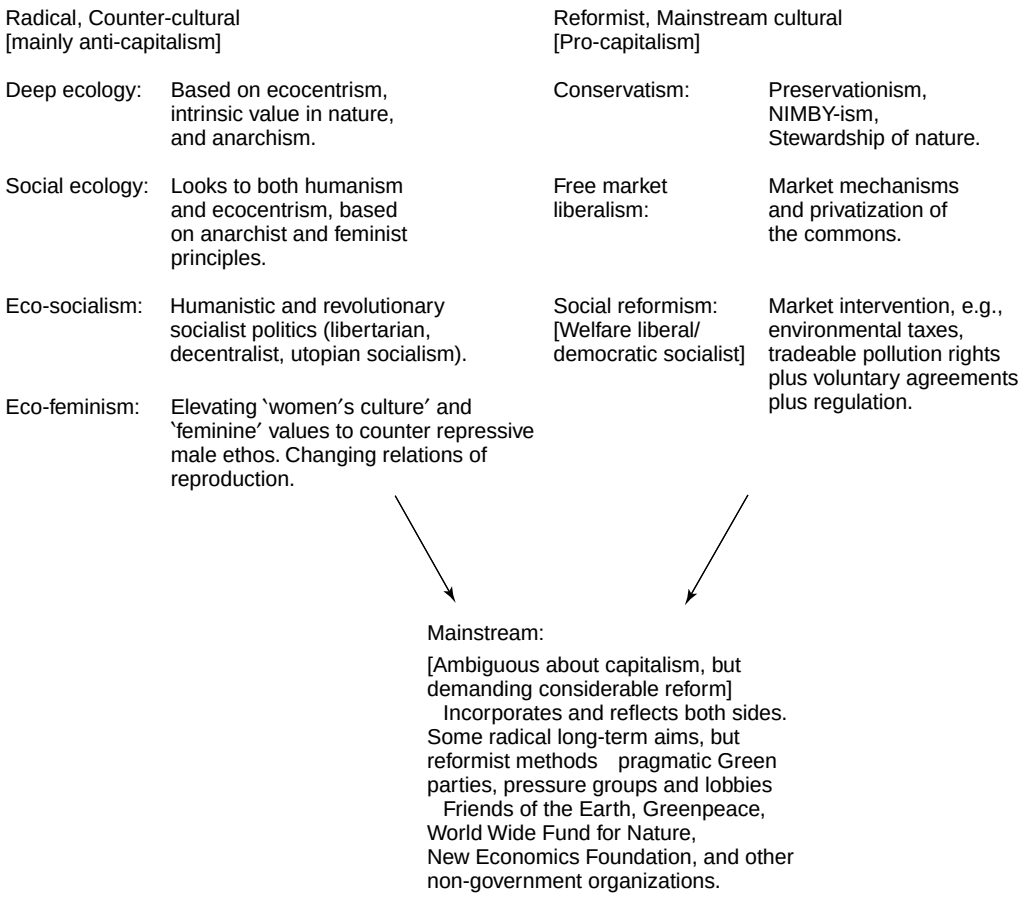

Figure 1 Environmentalisms and their political ideologies and approaches

Mainstream environmentalism, as represented by the movements and groups discussed above, tends to be a hybrid – a *mélange* of both radical and reformist approaches. As also suggested, the mainstream environmentalist movement's proponents and actors often hold radical views (including eco-centrism and opposition to capitalism), but they may show pragmatism, believing that to make some environmental headway by reform is better than to make none at all. The works of some of mainstream environmentalism's most influential figures (e.g., Schumacher, 1973; Porritt, 1984; McKibben, 1990) contain currents of socialism, anarchism, conservatism and social reformism.

The following discussion will illustrate how elements of traditional political ideologies inform both radical and reformist wings of the environmental movement, before going on to consider what aspects of green political ideologies might be considered as unique.

Before commencing it should be stressed that assessing green thinking against more traditional political ideologies is fraught with difficulties. Political philosophies are mainly diffuse rather than tightly coherent, changing and evolving with time. They also contain inconsistencies, they overlap, the terminology is confusing, and there may be considerable differences between what is popularly thought of as, say, liberal or socialist and what in theory they are. Popular views of political ideologies are colored by the utterances of party politicians, but there are few correspondences between political parties and the political philosophies they might claim to represent. And because party politics is political' there may be deliberate or unintentional attempts in debate to misrepresent them: because they are defined and evaluated subjectively, different people will make different interpretations of what they are. Additionally, political ideologies tend to differ in their interpretation between different countries. The view of them given below is written from a Euro-centric perspective, based on the British experience.

Finally, it should be acknowledged that it is one thing to note similarities between, say, anarchist and green ideologies, but this does not necessarily signify historical links between them – in the way of common threads of thinkers, writers or activists. Anarchy, like other political philosophies, comes specifically from political activism and social theories. By contrast, the green movement over the past

half-century originated from the concerns of *scientists* (like the Ehrlichs, Hardin, Fraser-Darling or Capra) who began to make political statements about society stemming from the results of their scientific work. They were not founded in any way on what the likes of Edmund Burke, Karl Marx or Peter Kropotkin wrote about – such figures were invoked afterwards. Hence the early statements from environmental movements were often politically naive and ideologically incoherent.

TRADITIONAL CONSERVATISM

The words conservation' and conservatism' both have the same root. And the ideas of tradition, continuity, stability, and dislike of sudden change but an acceptance of slow organic change (i.e., which is not planned or blueprinted or revolutionary) all feature in conservative thinking and all are compatible with at least some environmentalist thought. In conservatism the analogy between society and nature is strong: just as ecosystems need to be changing organically, not precipitously, so does society. As with nature, variety and structure in society are essential to achieve the all important goal of stability. Social revolutions (and new technology) upset the natural' social order. Conservatism perceives this order to be hierarchical, though this does not mean that respect is not due to those lowest in the chain of being. Hence relationships between higher and lower orders might be oppressive and economically exploitative but they nevertheless involve mutual obligations: they are not just one-way. However, those lower in the social order should accept the naturalness and inevitability of their position.

Such beliefs foster a romantic view of traditional' societies. So also is there a liking for traditional' pastoral landscapes and grand architecture, expressed in reformist environmentalism in Britain in the work of long-established nature and conservation groups like the National Trust, Councils for the Protection of Rural England and Wales, County Landowners Association and the Civic Trust. Conservative environmentalism involves a conception of stewardship' on the part of landowners – holding the land in trust for a future generation (again there is the idea that social obligations attach to power). This draws on Edmund Burke's injunctions about wise stewardship, and proposes that long-cherished virtues of efficiency, order, thrift, self-help, tradition, patriotism and nationalism should be the basis of environmental politics.

Faced with the dilemma posed by Garrett Hardin's (1968) commons' parable, in which individuals tend to use the resources of Earth's commons profligately because the costs of so doing accrue to society as a whole rather than to them specifically, conservatives would usually argue for enlightened private ownership of the commons as the best way to value and conserve them. They might also accept Hardin's (1974) arguments for coercion to curb population growth, and to promote the social and environmental consciousness appropriate for population control.

Edward Goldsmith (see, for instance Mander and Goldsmith, 1996) is a prominent radical environmentalist who seems to argue for conservative values. He wants to see Western societies re-embedded in strongly held belief systems, such as those enshrined in religion, for he thinks that strong religions are stabilizing forces making for social unity. Goldsmith has held up the caste system in India as the kind of social organization, which is compatible with an ecologically and socially sound society – sound because it is stable, and in balance with the natural environment. The way of life, like the structure and mechanisms of an ecosystem, is designed to maintain order. A sustainable society's common values must, above all, involve respect for ecosystems – this respect must be absolute and not negotiable. In common with many environmentalists (such as the more liberal Fritz Schumacher), Goldsmith argues for small-scale organization as the geographical basis for achieving the other desirable things. His radical environmental conservatism starts from the assumption of the family as the essential unit of social organization: what preserves this (such as the traditional stereotyped role for women) is to be encouraged. And it rejects industrial society' as aberrant. The desire to recapture small-scale traditional' society leads Goldsmith constantly to idealize primitive' peoples and tribes in Africa, Australasia, etc. Deep ecologists seem particularly inclined towards such idealization of pre-modern societies. They often hold up the North American Indian', for instance, as a paragon of ecological virtue, citing religious beliefs which apparently regard nature as part of the tribal community and require it to be treated with much respect (see for instance Callenbach, 1981). Archaeological evidence, however, often suggests something rather different; that notwithstanding beliefs, native American' actions towards nature may have been frequently exploitative (*see* Religion and Environment Among North American First Nations, Volume 5).

Economically, contemporary conservatism partly embraces neo-liberalism, as expressed in the doctrines of Adam Smith, since this revives the free market tradition which marked the beginnings of industrial capitalism. This seems particularly true in North America, for although many Thatcher conservatives in Britain did follow Smith, other more traditional' conservatives expressed misgivings at their lack of wider social responsibility to those low down in the socio-economic hierarchy.

Traditional conservatism may grade into fascism, also known as right-wing irrationalism', or extreme' romanticism. Some consider that Hitler spoke about the homeland almost in an ecological sense, using biological analogies of race, soil, homeland, folk and blood to describe the state as a living organism in developing his imperialistic theories. Bramwell (1989) describes how European Nazis showed

a liking for vegetarianism, the back-to-the-land movement and bio-dynamic farming. She observes that neo-fascist organizations in Europe have all taken onto their platform a green' perspective. Fascism's key elements include the use of biological metaphors, the stress on the organic community and the individual's need to merge with it, the elevation of ritual, intuition, and the mystical, and the distrust of the rational. These elements may be found in some ecological writings, especially those promoting deep ecology activism.

However it is unlikely that environmental movements as a whole would become fascistic because of their fundamental globalist inclusivism. That said, there have in the past been calls for a marrying of some of the elements identified above with a centralized authoritarian state (see Heilbroner, 1975; Ophuls, 1977), though without the crusading rejection of rationality necessary for fascism to exist. Heilbroner and Ophuls reached their authoritarian prescriptions reluctantly: but they were very pessimistic about the global condition, and thought that the nature of the required remedial action was so radical and electorally unpopular that no other institutional arrangement could possibly deliver.

FREE MARKET LIBERALISM

A strong ideology in the nineteenth-century, free market liberalism, was revived in the late twentieth century in the neo-liberalism which tends to support global marketisation. It is advanced by techno-centric environmentalists like Anderson and Leal (1991), following the example of Simon and Kahn (1984). They are aggressively optimistic about the free market's potential, allied to technology, to solve environmental problems. The invisible hand of market forces under which individuals pursue self-interest, they argue, gives society more environmental protection than will any kind of intervention or regulation, which is a constraint on liberty. Thus if a natural resource' is running out, its increased scarcity will push up the price of the goods or services that come through that resource. This will encourage entrepreneurs, with scientists and technologists, to devise some substitute for the resource, or more ingenious ways of providing the same goods and services. Similarly, there is money to be made from clean technologies like non-harmful aerosols, biodegradable plastics, catalytic converters and the like, so, as ecological modernizers say, there is no practical dichotomy between the interests of capitalism and environmental quality.

This ideology also underlies calls for privatization of the natural resources of the earth's commons. Its basic argument is that property held in common tends to be neglected, whereas individuals look after what they own. If private owners were to abuse or run down their resources, they themselves would suffer. And if others polluted their resource (their land or the waters within it), they could have recourse to law, which would defend their property rights. Groups of citizens might also sue the originators of pollution which lowered the quality of the air or the seas in their neighborhood. (This philosophy thrives particularly in the United States, where ordinary citizens have frequent recourse to law.) In response to objections that the originators of pollution may be hard to identify, the free-marketers might suggest technological solutions, such as the possibility of tagging' all emissions with trace amounts of identifying chemicals.

The free-market ideology also underlies systems of tradeable pollution rights, initiated in the US in the 1990s (*see* Tradable Permits for Sulfur Emission Reductions, Volume 4). The Federal Government sells to industry the rights to emit, for instance, sulphur dioxide. The total amount of rights issued conforms to a ceiling determined by Government as appropriate to an area: this ceiling can be raised or lowered as thought fit. If a firm's productive processes exceed the amounts of pollution that it has rights to emit, it can either pay to install cleaner technology or buy further rights from other firms who have less need for them. So far, this approach has met with limited success.

SOCIAL REFORMISM (ALSO KNOWN AS WELFARE LIBERALISM, DEMOCRATIC SOCIALISM)

Social reformists also believe in capitalism, but not without restraints and controls to limit its harmful effects on some people (the economic losers) and the environment. They emphasize the role and supreme importance of the individual and his/her enlightened self-interest in protecting the environment. In Western pluralist democracies, the parliament or congress constitutes the main forum through which environmental views and interests will be heard and protected. Rationality, the rule of law, technology and environmental and economic management (cost-benefit analysis, reform of taxation) will all help to secure the goals of environmentalism.

Following the father of English liberalism', John Stuart Mill, social reformists are ambivalent about how desirable unselective economic growth is, appreciating also the need for diversity in society and nature (compatible with their belief in pluralism). Support, is still strong for private ownership of resources, and the notion of the invisible hand' by which individuals seeking to maximize their personal benefit allegedly bring greatest aggregate benefit, to society. But they are also aware of the wider society and communal good, and that what is good is what brings most benefit and happiness to most people (Bentham's utilitarianism). By this measure, environmental protection is rational and desirable. Hence planning laws, taxes on non-recycling industries or pollution, and welfare provision to enhance urban environmental quality and environmental

education, are all legitimate ways for the state to intervene, but only as much as is strictly necessary, in the free market.

Social reformists are generally techno-centric, and many of their approaches underlie ecological modernization. They are predicated on significant government intervention in the free market, manipulating it in favor of environmental measures. Hence they advocate tax incentives and disincentives, permits and other moderately coercive management devices to control pollution and the use of environmental resources in the earth's commons'. The rationale behind the eco-consumerist movement owes much to welfare liberalism's belief in enlightened self-interest (i.e., that educated, informed and rational people are aware of the benefits to themselves of not behaving totally selfishly and without thought for wider social and environmental interests).

In Europe, social reformists are found in all mainstream groupings, including Conservative, Liberal, Social Democrat/Democratic Socialist and Green parties. As social reformists, democratic socialists emphasize their belief in the need for pluralist democracy and the power of parliament as the major way to achieve social change. Many now believe that capitalism can be reformed to take on board traditional socialist aims if it is guided and occasionally coerced by a moderately strong central and local state. Few influential members would advocate the necessity of abolishing capitalism or the global market as the answer to contemporary social or environmental problems. However, this form of socialism would like production to meet social and environmental needs alongside the exigencies of profit creation, hence it can be quite strongly interventionist in the free market. It may, too, favor decentralization of many of the state's functions.

The approach to sustainable development advocated by the UK's Real World Coalition' of environmental and social welfare groups (Jacobs, 1996) is essentially social reformist. It might be argued that in today's climate of neo-liberal global marketisation, based on extending and derestricting free trade and competition, their aspiration to elevate social inclusion and environmental sustainability considerations to a level of importance equal with profitability is somewhat utopian (*see* Political Systems and the Environment: Utopianism, Volume 5).

REVOLUTIONARY SOCIALISM

For years, many environmentalists have dismissed socialism as being equally culpable with capitalism in creating environmental crisis. They have regarded it as part of mainstream culture because of its unashamed anthropocentrism, and would therefore baulk at seeing it categorized in Figure 1 as engendering a form of radical *environmentalism*. But socialism itself is more complex than they seem to believe. And eco-socialism derives from particular socialist traditions that in fact have nothing to do with the kind of materialism and disregard for nature traditionally associated with the state centralist, self-styled socialist' regimes behind the old iron-curtain. Eco-socialism's roots lie in utopian socialism and the Marxism of William Morris (*see* Political Systems and the Environment: Utopianism, Volume 5, and Wall, 1994), rather than Stalin. As such, it is clearly counter-cultural, radical and opposed to mainstream values. Though eco-socialists and social ecologists criticize each other, they also have much in common.

Revolutionary socialism is a minority political current, unlike reformist socialism. However, together with anarchism it has strongly influenced all radical environmentalism. It fundamentally rejects capitalism and advocates production for social need but not profit, and common ownership of the means of production and distribution; thus it would deal with the commons' problem by having these areas under genuine common ownership and control. It contains different schools of thought about the role and importance of the state in revolutionary and post-revolutionary society. Though the state has no place in the ultimate communist society, a more democratic and decentralized form of state than exists in most contemporary Western society may be seen as important in helping to create a transition towards that society. Revolutionary socialism's analysis of the society–nature relationship generally follows Marxist lines, seeing nature and environment as socially produced', and environmental problems as inherent in the nature of capitalism. Again, opinions differ on how much they may be *solely* located here. The analysis of how to get to an ecological' society – which equates with a (perhaps moneyless) communist one, is based on the mechanism of class struggle. Neo- and orthodox Marxists, however, may differ amongst themselves on who might be the principal agents and actors in creating this society – faith in the potential effectiveness, or even existence, of a working class proletariat' is not universal amongst eco-socialists (see Gorz, 1982).

Marxists tend to see the rise of environmentalism itself in class terms, sometimes regarding it as bourgeois and counter-revolutionary. This may mean open hostility towards environmental groups and campaigns, though more often than not there is an uneasy alliance between reds and greens based on agreement on ends but not necessarily on means or analysis of causes.

Marxists by and large believe that environmental, feminist, peace and third-world campaigns are, or should be, all part of the ultimate struggle against global capitalism itself. From Marxism's materialist perspective, the ills which these campaigns highlight are all outgrowths of capitalist relations of production. Such campaigns, furthermore, should focus less on the reform of the individual's attitudes and values and more on the collective political struggle of the world proletariat'.

Major influences on European environmentalism, like Andre Gorz and Rudolph Bahro, have tended towards the revolutionary socialist view in the past, but no longer do so. The Socialist Party of Great Britain, Socialist Workers' Party and Militant (who spell out the eco-socialist case eloquently and simply in Cock and Hopwood, 1996) are all British political groups who incorporate green issues into orthodox Marxist analysis.

GREEN ANARCHISM

Anarchism suffuses all varieties of radical environmentalism, including deep and social ecology, eco-socialism and eco-feminism. Anarchistic groups within environmentalism share fundamental beliefs about the need for organic societies' but some are anti-urban and anti-industrial, so displaying affinities with conservative thought. American eco-anarchists may incline towards radical, libertarian liberalism. Indeed, in espousing the individual as the basic social unit, anarchism is sometimes thought to embrace the cornerstone of liberalism although anarchists might define concepts like individual' and freedom' in ways different from that of a mainstream liberal.

But then much anarchism has major affinities with socialism, and it is probably true that eco-anarchists are mainly anarcho-communists, looking particularly to Kropotkin for inspiration (*see* Political Systems and the Environment: Utopianism, Volume 5), or possibly anarcho-syndicalists (based on trade unions as major revolutionary agents). There is the rejection of capitalism, desire for common ownership of the means of production (resources), and, in resource and income sharing communes, with distribution according to need. But, unlike socialism, there is strong rejection of any possible role for the state, intermediate or not.

Eco-anarchism informs the rural communes movement, but may also inspire urban communes, the urban Reclaim the Streets' movement, the squatter movement (property is theft') and self-help urban community groups. The urban movement is particularly strong in North America, while in Australasia, anarcho-syndicalism – which is uncompromisingly urban-centered – has been a powerful force in green/trade union activism. Anarchists are prominent in what is becoming a world-wide militant movement against global capitalism in the early twenty-first century.

Notwithstanding the common roots and many correspondences which exist between eco-anarchism and eco-socialism, there are also some major divergences between the two (see Pepper, 1993). For instance eco-anarchists often reject the old class politics, seeing social change as consequent on the action of individuals in forming spontaneous, mutualist, non-hierarchical groups to live out their politics, thus setting an example for others to follow. The personal is political', and person equals planet' are maxims from more liberal American anarchism (i.e., Roszak, 1979), which appear to have great influence. Anarchism considers that social hierarchies and not class constitute the key to oppression: hence eliminating hierarchy is the prerequisite for eliminating oppression. Socialists argue the reverse, insisting on the need for revolutionary political class struggle to change the relations between people, which are contingent on the material, economic, organization of production. Anarchists with an emphasis on practical lifestyle politics believe that only by people sidestepping (living outside) the economic and social structures of conventional society can those structures be overthrown.

FEMINISM

The notion that we must eliminate social oppression and hierarchy if we are to form an ecological society is but one of many ideas, which are held in common between feminism and anarchism as applied to radical environmentalism. Eco-feminists often propose an essential convergence between women and nature. This is firstly because their biological makeup inevitably associates women, more than men, with the natural functions of reproduction and nurturing. Secondly, women and nature have in common that they are exploited by men, both economically and in being objectified and politically marginalized. During and since the 1970s, debates within eco-feminism have focused on several schools of thought, including cultural eco-feminism and social (socialist/anarchist') eco-feminism (*see also* Ecofeminism, Volume 5).

Cultural eco-feminism considers that the root problems of how Western cultures treat nature could be solved by a women's culture', providing practical and philosophical guidelines to sustainable development. Since menstrual cycles follow phases of the moon, and fertility follows the rhythm of the seasons, then women might be regarded as inherently close to nature. Hence eco-feminist culture would draw on ancient myths combining women and nature, mother and earth, in cooperative relationships: caring, nurturing, mutually giving and receiving.

This eco-feminism says, further, that female culture' is concerned with the body, the flesh, the material; with natural processes, emotions and subjective feelings and private life. By contrast, male culture' emphasizes the mind, intellect, reason, culture, objectivity, economics and public life. Male culture always seeks to transcend natural constraints on what humans can do: men constantly fight to conquer, exploit and mould nature to leave their mark behind and achieve immortality and transcendence. Merchant (1982) describes how, during the period of the scientific revolution, Francis Bacon and the Royal Society pledged to reveal the secrets still locked in her [nature's] bosom' and to conquer' and subdue' her. Most high technologies, including new female reproductive technology, are developed by men

and are said by this school to constitute a continuation of men's dual domination of women and nature.

Cultural eco-feminism, then, means liberating nature from the repressive male ethos so that it will be respected as a sustainer of life. Capra (1982) urges the necessity for a return to a balance of *yin* and *yang* characteristics in people and society as the foundation for a new, ecologically benign society (*see* Land Transformation in China: 3000 Years of Human Ecological History, Volume 3). This might be achieved through women, individually and in groups, discovering their authentic natures and celebrating and affirming them. Such consciousness-raising may need to exclude men, on the grounds that they could have a negative impact on it while it is still nascent and before it is strong enough to resist male domination. Then there can also be celebration of pagan myths and rituals, and associated pastimes like tarot cards and astrology, which affirm respect for Mother Nature and the essential interconnectedness of humans and nature.

This latter leans towards New Age thinking, and some greens and feminists (particularly of the social variety) reject it. As Plumwood (1993) argues, the whole idea of connecting with nature' could be regressive and insulting, portraying women as passive reproductive animals immersed in the body and in unthinking experience of life.

Materialist social eco-feminism draws on traditions in non-mainstream European socialism, including utopian socialism, classical anarchism, early Marx and William Morris' work. They all insist that exploitation of nature relates to exploitation in society, emphasizing social and political rather than personal aspects of the domination of women and nature. Hence women's oppression is seen as interwoven with class, race and species oppression. But social eco-feminism also rejects the crude economic class reductionism of some Marxism; so it does not accept that women's oppression is *merely* a special case of exploitation of the proletariat', or that to establish socialism would mean automatically ending women's or nature's oppression.

Mellor (1997) wants to modify or reconstruct' Marxist theory, to make a socialist eco-feminism. If, she argues, the way societies organize themselves to get material subsistence (economic relations of production) plays a key role in shaping society, so also must the way we organize ourselves to materially continue as a species (i.e., the relations of reproduction). Hence the material world of motherhood, not merely the (still largely male) material world of industrial production, should provide ideas and values for shaping an alternative (socialist) society. These ideas and values are altruistic: they include taking immediate responsibility for meeting the needs of others. But as things stand, the dominance of capitalist relations in Western society ensures that the stereotypically male' standpoint mediates all knowledge. Its view of nature as a commodity will prevail over the female view of unity with nature.

Other calls to construct a social eco-feminism often emphasize the importance of ideas and attitudes, calling on women to unite with the environmental movement to reshape the underlying values of a conventional society based on hierarchical organization and domination of some people by others. According to Plumwood, one of the major wrong ideas in our culture is the tendency towards dualistic thinking. For, as Eckersley (1992) suggests, patriarchy is a subset of such thinking – the philosophical dualism that has pervaded Western thought'. So, for instance, imagining that there is a fundamental distinction between society and nature suggests that they are separated, making it easier for the former to exploit the latter. And strongly identifying women with nature, as in cultural eco-feminism, implicitly or explicitly links men with exploitation of both. All this reinforcement of dualistic thinking feeds that very patriarchal culture to which feminism is opposed.

Eco-feminism shares with socialism an internationalist mentality; opposing women's oppression worldwide. It recognizes that in the third world, *women*, not men, constitute the backbone of production' as well as reproduction'. Eco-feminism in this context has therefore meant pushing for women to be involved in decisions about land use and control. Eco-feminists have resisted land appropriation by government and (Western) commercial firms, while, however, the men – who own the land – have often given in to the seductions behind the modernization model of development.

While some third-world women have been co-opted by modernization, helping to provide the cheap labor for inappropriate development such as dams and nuclear power stations, others in the 1980s have instead adopted the bypass' strategy. They have set up enterprises and movements that attempt to exclude the involvement of international capital (e.g. Chipko in India, South African cooperatives, green zones' in Mozambique). They have supported, therefore, a localized development model rather than global modernization.

MAINSTREAM GREEN IDEOLOGY: OLD OR NEW POLITICS?

Bearing the mark of all these influences, mainstream green political ideology, or ecologism' (Dobson, 1995) is an eclectic, pragmatic and shifting mix of ideas, but with some recurring themes. Green activists often hold it as a point of principle that they are neither left or right, but forward', or above the old politics': The basic political choice today is not between Right, Left or Center, but between conventional gray politicians and the Green Party', said that party's 1992 UK manifesto. But of course, when they start to talk about what we should do about the eco-crisis, environmentalists must become involved in old' politics. Hence the ideology of ecologism contains tensions between:

1. Ecology-based politics, emphasizing the pre-eminence of sustaining natural systems as the universal basis for social organization. Such eco-centrism constitutes ecologism's main claim to be a new politics.
2. Socially-based politics, seeing ecological problems as outgrowths of social problems, and seeking to solve the former by, first and foremost, solving the latter. These constitute the old' politics, raising questions, which have been the concern of traditional ideologies for several hundred years.

Environmentalists who concentrate on the second category often seem to follow a relatively coherent and identifiable analysis of the problems and sets of prescriptions to remedy them – i.e., they align with one or other of the more traditional political ideological camps. Most of those in the first category, who prioritize eco-centric concerns, present a more diffuse image, spreading themselves across the political spectrum and accumulating bits of traditional liberal and socialist ideology, spiced with dashes of conservatism. In the terminology of the old politics, perhaps a majority of these eco-centrics gravitate towards social reformism (especially in their public utterances), while a vocal minority embrace, especially, eco-anarchism, in the context of one or more of the radical camps' outlined in Figure 1. But for all those in this first category, politics start from the perspective of *ecology* and the need to maintain eco-system integrity. For those in the second, social matters are as important (or more so) than ecological ones: they are fundamentally anthropocentric.

An overall predisposition towards social reformism emerges in common mainstream green positions, which say that social change must proceed from individuals, but that change is also needed in the economic structures of society. They often do not totally reject capitalism – indeed are enthusiastic for at least small-scale versions of it, but see social need and environmental quality as criteria to be elevated above the profit motive. They see a crucial but benign role for the state, in both facilitating the development of individual responsibility and laying down regulatory and legal frameworks governing group behavior in particular. This (grudging) acceptance of the state (and of parliamentary politics by Green Party supporters) wanes where eco-anarchism acquires more influence.

Nature is the ultimate legitimation for and the source of social laws in the mainstream green canon. But, as noted above, matters of social justice are increasingly important to most environmentalists. Technology is not rejected, but it must be appropriate and democratically accessible to all, as well as soft' on nature. Scientific knowledge and rationalism are regarded as useful, but many environmentalists insist that these must be balanced by elevating emotional and intuitional knowledge to a more influential position in environmental decision-making than that currently accorded. Democracy and individual freedom are cornerstones of mainstream green ideology. Democracy is to be extended to all nature's creatures (animal rights, vegetarianism, veganism). But the importance of the community is also stressed. However the collective, e.g., trade unions in the production processes, is not seen to be as important as in traditional politics. Emphasis in mainstream green ideology, as in social reformism generally, has swung from our collective power as producers to our individual power as consumers.

The disdain for the industrial way of life', and the old politics' which was noted above in connection with early environmentalism, still persists as a current in mainstream environmentalism. It may be coupled with a tendency towards irrationalism and mysticism – which becomes more strident in deep ecology and New Age approaches. Whether they publicly own or disown this spiritual wing of the radical ecology movement, it is apparent that most mainstream greens do have deep ecology/New Age tendencies'. This shows in their support for a bio-ethic, for nature mystification (Gaianism), and their belief in spiritual paths and self-discovery, self-realisation and consciousness raising through therapy techniques as routes to political change. The innate conservatism in idealizing nature, and in the denial of a politics of social change in favor of one of individual change, is often uncomfortable to those more on the left of the green movement.

STRATEGY

If mainstream green thinkers and activists do show an eclectic mix of pragmatic politics, taken partly from old reformist and radical political ideologies, and putting an ecological emphasis onto the whole, this could be seen in positive or negative terms.

On the positive side, it could be argued that mixing elements of older ideologies will produce something more appropriate to the modern world – which is not the world in which these ideologies were formulated. Thus a politics can be reached which is compatible with the needs of an ecologically sound society: these needs might best be seen not in the old terms of class war or material wealth distribution alone. An ecological crisis like holes in the ozone layer threatens us all, and in any case so-called socialist societies have not had a better relationship with nature than capitalist societies. Such a common sense' approach to politics might also appeal to a wide range of people, not being seen as extremist'.

More negatively, the result of doing this could be merely an ideological mish-mash. It might sound theoretically appealing but is destined to break down in practice, because it contains some irreconcilable contradictions. (Such as the idea proposed by some environmentalists that green consumerism and other pressures will create multinational corporations that are environmentally sustainable

and will put environmental and social goals before that of profit.)

Ideological inconsistency could lead to some strange conceptions of a sustainable society, as conveyed by some libertarian environmentalists. They demand significant increases in personal freedom, and an end of state domination of society. But at the same time they campaign for potentially repressive universal laws embracing the interests of natural' eco-systems. This could lead to a society where communities which sanctioned the dumping of toxic wastes could be heavily punished, but those who allowed child abuse or racism to flourish might be excused on the principle that local communities should have an absolute right to self-determination in the social sphere.

For one of environmentalism's recurrent themes is respect for a diversity of cultures, i.e., respect for otherness'. Part of the contemporary debate about environmental politics concerns such post-modern sentiments, along with the tendency discussed above to reject progress' and modernity. While some greens like Atkinson (1991) are content to see environmentalism as essentially a form of post-modern politics, others are anxious to rescue the Enlightenment Project and the gains from the Industrial Revolution for environmentalism. John Barry (1999), for instance considers ideological' green politics in relation to the French and industrial revolutions. He thinks that they want to accept and radicalize the democracy begun by the former, but to reject the industrial revolution. This latter would be mistaken, he believes. He says, probably correctly, that green politics should be an immanent critique of modernity' which however does not want to reject progress': rather, to redefine what is meant by the word, making it apposite to strong sustainability principles, including social justice and ecosystems integrity. With this approach, the promise of modernity, which has hitherto eluded the majority of the world's people, will not be forgotten, but can perhaps be realized for this majority.

Political Systems and the Environment: Utopianism

David Pepper
Oxford Brookes University, Oxford, UK

Utopias are imaginary locations with perfect social and political systems. Utopianism is strong in environmental thought, where political and economic commentators often spell out the principles of an ecologically sound society, and writers of ction create ecotopias: ecologically ideal societies of the future. Additionally, environmental activists may set up small, would-be ecotopian communes, where they try to practice self-suf ciency within non-hierarchical social relationships.

The ecologically ideal society is usually envisaged as small-scale and decentralized, with local communities forming the basic social, economic and political unit, but larger units are also formed through confederation. Environmental and social quality of life is high, and consumption of material goods is low in these local economies where production is for social need, not pro t. There is direct democracy, and nation states and international trade via multinational corporations play a subordinate role, or are non-existent. Nature is respected and stewarded, and biodiversity is high.

Ecotopianism draws on utopian activists and thinkers of the past, including the 17th century Diggers and the utopian schemes and experiments of anarchists and utopian socialists such as Charles Fourier and Robert Owen in the early 19th century. The late 19th century writers, William Morris and Peter Kropotkin, have perhaps been the greatest historical in uences. Their socialist and anarchist visions are apparent in today's social ecology schemes for an ecological economy and society, while Teilhard de Chardin's mid-twentieth century ideas about the evolutionary progress of humankind have particularly in uenced deep ecology's view of a future perfect society.

Utopianism is also a term sometimes applied to those who seem to have unrealistic, impractical and ill thought out ideas about society's future direction. It is not only the idealistic schemes of radical environmentalists which are prone to this somewhat derogatory charge. The vision of the future proffered in the mainstream model of development known as ecological modernization (EM) could also be guilty of utopianism. For it imagines a future highly competitive capitalist, free market global economy where matters of social justice and environmental quality are given equal or greater priority than the pro t motive; a somewhat unlikely scenario perhaps.

INTRODUCTION: MEANINGS OF UTOPIANISM

The Oxford English Dictionary defines *utopia* (no-place) as an imaginary location with a perfect social and political system. Most contemporary thought and action about the environment could be described as utopian in some way. Environmentalists, be they radical or reformist (*see* Political Movements/Ideologies and the Environment, Volume 5), wish to see significant change towards a much improved society where development will be sustainable, that is, where the old antipathy between the exigencies of human progress and the integrity and diversity of natural ecosystems is resolved in some kind of harmony.

Kumar (1988) describes utopianism as a form of thinking, invented by Thomas More (*Utopia, 1516*), which became a social movement in the West in the 19th century. From then on, some people, including environmentalists, have striven to realize utopia here on earth. Whereas earlier utopias, including those of the Renaissance and Enlightenment, were Christian-based (Manuel and Manuel, 1979, referred to hereafter as the Manuels), Europe and America were swept in the 19th century by a wave of secular messianism, of which socialism was the dominant expression.

Kumar identifies three locations of utopian expression:

1. in practical experiments, for instance of Robert Owen and many New World communities;
2. in fictional societies, like Etienne Cabet's *Icaria*;
3. in social philosophies, such as those of Saint-Simon, Fourier, Comte and Marx.

These examples were all socialist-leaning, and a related ideological movement, that of anarchism, has been much connected with socialist utopianism. Both are extremely germane to contemporary environmentalist utopias, heavily influencing classic ecotopias; such as those of Reich (1970), Schumacher (1973), Le Guin (1974), Goldsmith *et al.* (1972), van der Weyer (1986) and, notably, Callenbach's *Ecotopia* and its prequel *Ecotopia Emerging* (1978, 1981). But there are also other influences, such as Pierre Teilhard de Chardin's *Phenomenon of Man* (1965), which feeds strands of idealism and technological optimism into, particularly, deep ecology/new age utopianism: this also sometimes reflects the utopianism of capitalist free market ideology.

Authorities on the utopian subject, such as the Manuels, regard Marxism as a secular resurgence of millenarian (believing in a period of good government, great happiness

and prosperity ; Oxford English Dictionary), paradisaical, apocalyptic thinking. Marxism is an unchristian euchronia (looking forward to an ideal time rather than place) in as much as it sees a future society of inde nite progress and growing freedom. In it, Men make their own history in full consciousness of their power, collectively, to shape their own society, and not subject to forces, economic, historical or mystical, beyond their control. (Socialists, however, often deny that Marxism is utopian, since Marx speci cally rejected the notion that members of a future communist, free society should be shackled by visions and blueprints inherited from previous generations.) Many environmentalists today, whether they call themselves Marxist or not, assert similarly that the key to an ecologically benign society is an inclusive democracy where the will of the majority prevails over economic and social decision-making. Armed with such freedom and with reason, they argue people will avoid living inharmoniously with nature, since this would undermine majority interests.

As the Manuels point out, utopianism is popularly associated with a literary genre: a dramatic narrative portrayal of a way of life which is essentially good, embracing the underlying principles of an optimum society and embodying a set of implicit (usually optimistic) assumptions about human nature. But additionally, utopianism is a state of mind which often appears in the constitutions of a restructured polity and in the plans, outlines or blueprints of a universal republic. The line between such idealized blueprints and political and social theory is often blurred.

The Manuels also show how utopianism is tied to speci c social con icts, and utopians, in rejecting the existing society, take political sides. Much late 20th century utopianism (including ecotopianism) re ects the condition of post-modernity, in its skepticism about modernity and the Enlightenment Project (the mission expressed strongly in the 18th century, and founded on scienti c, technological and industrial development in pursuit of universal material and social progress). Progress, as expressed through material af uence and the achievements of science and technology are often eschewed. The nuclear family, Fordist production, global modernization: all may be conspicuous in contemporary utopianism by their absence.

The Manuels refer, almost disparagingly, to specialist utopias (including environmentalism and feminism) identifying with 1960s and 1970s counterculture, which arose in response to post-industrial apocalyptic visions of overpopulation, nuclear disaster, or Frankensteinian experiments gone wrong. (Two ecological dystopias which incorporate such visions are by Harrison (1966) and Wright (1997)). These, in true post-modern fashion, often entirely rejected theory. They had, the Manuels say, no identi able character beyond being usually virulently anti-urban. A bit of transcendence, body mysticism, sexual freedom, the abolition of work, the end of alienation, they wryly add (p. 808), noting that this countercultural utopianism appealed to young people who found conventional society wanting, but it was, unlike earlier utopianism, not oriented to the long idealized future. Rather, it related to immediate existence and to the miniature rather than the large-scale model. This seems only partly true of ecotopianism at the end of the 20th century, which tends to bear out the Manuels view (p. 803) that however much it appears to change, the ••• utopian bazaar is cluttered with old fashioned wares that are all too familiar.

The picture is complicated by the fact that, of course, not all contemporary utopianism is countercultural. As will be argued below, the neo-liberal utopianism of the free market suffuses today s mainstream ideology and practice of global modernization, and its mainstream environmental component, known as *ecological modernization* EM. The case for identifying this as utopian rests on a normative interpretation of the word which is particular to Marxist thought. Essentially, this holds that while it may be valid to envisage and facilitate social change (i.e., towards socialism), it is utopian, i.e., unrealistic and impractical, to do so in a way that underplays the importance of factors (especially economic) militating against such change. The charge of utopianism, in a derogatory sense, was leveled by Marx and Engels against the utopian socialists such as Robert Owen, and the anarchists:

> What was designated utopian according to this approach, was the imagination of the possibility of total social transformation involving the elimination of individualism, competition and the sway of private property, *without a recognition of the necessity of class struggle and the revolutionary role of the proletariat in accomplishing the transition.*
>
> (Jones, 1983, 505, emphases added)

By extension, this means that the approach of some eco-anarchistic alternative communities, who think it possible to create in the midst of capitalist society a coexisting microcosm of a non-capitalist utopia, which it is hoped might spread by example, is utopian, naive, and doomed to failure. It also implies that social democratic attempts to reform capitalism, rather than replace it by radically changing its economic character and relations of production, (the EM approach) are similarly unrealistic and destined to remain in that place called *nowhere*.

RADICAL ENVIRONMENTALISM'S ECOTOPIA SUMMARIZED: THE IDEAL MODEL OF SUSTAINABLE DEVELOPMENT

Modern environmentalism bears the imprint of both radical and reformist political ideologies (*see* **Political Movements/Ideologies and the Environment**, Volume 5). There are four main strands of radical environmentalism: *deep ecology* (which often fuses into *new ageism*), *social ecology*, *eco-feminism* and *eco-socialism*. These strands are

politically diverse and often incompatible; yet they also share strong unifying features, in their intent, first, to replace current society by some form of radical alternative and, secondly, to ensure that this radical alternative should be intrinsically socially and environmentally sustainable and just.

A third source of unity is the very considerable commonality in their detailed visions of ecotopia/ecochronia. The lineaments and features of their economic, political and social life, and their geographies, have more in common than of difference. In terms of the contemporary jargon of models of sustainable development, ranging from weak to strong, the radical environmentalists' ecotopias may be seen as ultra-strong, or as Baker *et al.* (1997) term it, they constitute an ideal model (IM). One criterion by which this IM of sustainability differs from other approaches is that it does not countenance a role for conventional economic growth in its definition of development: rather it seeks development in other aspects of wealth, such as quality of life.

The account here draws on ecotopian works referred to previously, and also in Sale (1985), Devall and Sessions (1985), Kemp (1992), Milbrath *et al.* (1994), Mander and Goldsmith (1996), Douthwaite (1996) and Fotopoulos (1997); a fairly representative and diverse set of radical environmentalists. However, notwithstanding their divergences, they share most if not all of the principles outlined in Table 1, amounting to development aims of cultural identity, self-reliance, economic and social democracy, social justice and ecological balance. Working from such principles, some important elements of the economy, society and geography of the sustainable society corresponding to this IM can be pictured.

Table 1 Major principles underlying the ideal model IM of sustainable development

Economy
Economy's purpose is to satisfy need, not to create profit. Needs include satisfying, creative work, good health, spiritual and cultural fulfillment, social interaction and high environmental quality, as well as food, shelter, etc.
Communities/individuals define their own needs and satisfiers
Local production to meet local basic needs
Economic confederation and inter-regional exchanges to meet extra local needs, e.g., energy, transport, cultural, and non-basic needs
Mutual aid rather than strict reciprocity is the basis for any exchanges
Economic wealth should not be concentrated or taken out of communities
Total or partial common ownership and control of means of production and distribution
From each according to ability: to each according to need, within limits, or unconditionally
Holistic accounting
Sustainability and self-reliance imply living within limits: limits to economic growth and consumption
Stable human population levels
Community/regionally planned economy; markets have minimal or no role
Society and politics
Local community is the basic social unit
Confederation and inter-regional interchange (e.g., via information technology) to avoid parochialism, bigotry, conservatism, deviancy
Cultural diversity giving social strength
Participatory, bottom-up democracy, informed by subsidiarity
Individuals/communities take responsibility for their own lives
These last two imply economic democracy, direct political democracy, egalitarianism and non-hierarchical relationships, i.e., dispersal of power
Emphasized values include cooperation, non-hierarchy, non-patriarchy, equity, justice, social cohesion, compassion, love, peace, respect for nature
Holistic thinking
Science/technology controlled by and serves the whole community
Education a key resource, and tool for social change
State has an enabling role, or none at all
Nature
Valued for its own sake and/or for humanistic goals
Biodiversity fostered and preserved
It is axiomatic that the community focus of society fosters sustainable relationships with nature
Permacultural principles apply to interaction with the land
Each system/production cycle can continue indefinitely without ecological deterioration

Economy

Stability, self-reliance and cooperation are key IM concepts underlying production, work and distribution. Self-reliance would root communities back into their locality, decreasing dependency on the global economy. It implies as much self-sufficiency as possible, locally meeting basic needs for food, housing, welfare, and energy. Communities could generate their energy from multiple combined local sources; watermills, photovoltaics, windmills, and biomass such as straw, dung, woodchips from coppicing and forest waste. Contributions to and withdrawals from a grid would coordinate production, while conservation, and savings from reduced transport, would greatly reduce energy needs.

The principle of common ownership of the means of production in action would be seen in farms and horticultural enterprises owned by community land trusts and/or supported by subscribers paying for food in advance of or after distribution. Such enterprises exist today, and are usually small and substantially organic, utilizing low energy inputs and local plant and animal strains. Industries, services and shops would also be community supported. In Fotopoulos' eco-socialist/anarchist utopian economic democracy,

citizens' assemblies would make all the macroeconomic decisions. Micro decisions, on how individual factories and businesses operationalized citizens' targets, would be controlled by workplace assemblies delegating powers to supervisory boards.

Eco-socialist and deep ecology visions often dwell on the virtue of creative artisanship (rather than the current alienating division of labor) to fulfil the social aims of work. They may also emphasize team production, and the need for individuals not to over-specialize. However, this does not amount to rejecting specialist roles, including management. But possessing and exercising expertise must not create power hierarchies: there should be distinction without rank.

While some, like Sale, envisage labor without wage, looking perhaps to distribution via free shops, Fotopoulos dismisses this as being based on a socialistic fantasy of inherent abundance. He shares most green and neo-classical presumptions of inherent scarcity, and would distribute work, goods and services in his hypothetical non-money economy through a complicated scheme involving basic and non-basic vouchers. Everyone would receive the former for life's essentials, with a strong expectation that all able bodied people will work. Most would also do extra-voluntary work, for non-basic vouchers to exchange for community-designated luxuries (perhaps obtained through exchanges with other regions and communities). But whether vouchers or money were used, they would be only locally valid, after the manner of existing local employment and trading systems (LETS) schemes, and could not be accumulated or removed from communities by individuals.

In the transition towards the ultimate non-money economy, Fotopoulos envisages that people's savings and investments would be effected through local banking, credit union and provident schemes, which would all be amenable to confederation. In very many ecotopian visions, the anarchist's conferral principle would be vital in equalizing resources between communities, in investing in and organizing infrastructure, and in overall production planning. For Fotopoulos, outcomes, in individual incomes and wealth, might well be unequal, but inequality would result from individuals' voluntary decisions, e.g., to do less work, or perhaps to do the most sought-after jobs, which therefore might attract less remuneration than undesirable tasks.

Society and Politics

All ecotopias rest on the argument that more inclusive styles of government, oriented towards generalizable interests, are better suited to addressing environmental degradation than existing less inclusive styles. Inclusive styles are predicated on decentralized decision-making, including economic decisions. Hence, IM visions all revolve around communitarian values, reviving, says Douthwaite, the spirit of the Irish Meitheal, which was and is a working party system based on mutual support and trust within and between local communities. Such visions tend, Kemp *et al.* (1992) believe, towards true communism; where producers and communities join together to regulate rationally and for themselves their exchanges with nature; a situation increasingly rare within capitalism. This context fosters individuals' fulfillment, but not at the expense of others.

Most radical visions emphasize libertarian, anti-statist principles, but their society is also highly organized, needing strong civil institutions. The spatial division of power is intended to promote equality, efficiency, welfare and security. The fact that this may be utopian in the sense of unrealistic, is recognized by Le Guin, whose anarchist planet, Anarres, is by no means perfect. She sees that because of the principles of diversity and self determination, not every community or region would be likely to heed democratic, just and ecologically sound values. (Le Guin's quasi-utopia, incidentally, is more believable and palatable by virtue of its presentation, warts and all, as an imperfect society; often dour, austere and a place of daily struggle to maintain cherished principles. It is, paradoxically, more inspiring than the incredible worlds of William Morris, Huxley or Callenbach, where people seem perpetually wreathed in sanctimonious smiles of happiness). In detail, therefore, the search is for a system that works even if people in it are not good, with structures, or devices like peer disapproval, to minimize errant behavior undermining majority interests.

Fotopoulos supplies considerable structural detail of his future inclusive democracy. Its citizens' assemblies, taking local decisions, would be augmented through rotating, mandated, recallable delegates, on appointed bodies like community courts or militia. They would also send similar delegates to regional and confederal councils, where different community aims would have to be composited and operationalized via majority voting or consensus.

Geography and Understanding of Place

It is here, perhaps, that different versions of IM have most in common; all reasserting localism to countervail capitalism's inherent globalism. Global modernization's geography is one of dependency, whereby the lives of communities are shaped by events and decisions originating at considerable distances. By contrast the IM's decentralized geography would create protective space for communities and regions. In its communitarian cultures and collective economies, families and communities would own their means of livelihood. Its mainly small enterprises would minimize returns to capital and maximize returns to labor, and much investment would be in local rather than spatially distant regions.

To radical environmentalists, one key benefit of decreasing the scale of living would lie in enabling people to understand readily the effects of their actions on their community and its ecosystems. Communal ownership of the

means of production would preclude externalizing social and environmental costs, because there would be no external places. For where value systems fostered mutual aid rather than economic competition, it may be reasonably supposed that other parts of the world would be regarded as extensions of one's own community and region. The confederal principle, allied to information technology, should help such changes in geographical perception. Parochialism and spatial inequity could thus be avoided. Outside relationships and exchanges, not being based on strict market reciprocity, would likely foster non-dependent, non-injurious interaction and cultural tolerance, in what would be a global economy. Localism, by providing economic security, should create a climate where racism and authoritarianism would wither away. Nation states might also wither, giving way to continental and sub-continental confederal alliances. The European Union (EU) might become a series of autonomous regions within a unified European framework.

Bioregionalists, such as Sale, and many deep ecologists, seek to define regions by recognizing natural boundaries within which clear carrying capacity limits are acknowledged. Knowing about regional cultures, folklore, history and natural cycles would constitute a major element in bioregional citizenship, involving walking the territory and attuning consciousness to nature. A *bioregion* is any part of the earth's surface whose rough boundaries are determined by natural characteristics rather than human dictates, (Sale, 1985, 55). It is distinguished from other bioregions by particular attributes of flora, fauna, water, climate, soils and landforms, and by the human settlements and cultures these attributes have given rise to.

There is much variation in views about the maximum viable size of the primary political unit, the local community. Estimates may range from one to 10 000 people. This would clearly necessitate politically reconstructing most cities into relatively autonomous neighborhood units, confederated into city regions: perhaps, as Sale envisages, by breaking bigger cities down into smaller ones of 250 000 maximum size, generating their own energy. In this way, 150 new USA cities would be created. Additionally, cityscapes are much changed, as in Callenbach's *Ecotopia*, where gardens, rooftops, community allotments and city farms burst forth with the fruits and flowers of intensive cultivation. Douthwaite envisages that increased rural self-reliance would give city-based service providers less to do, encouraging countryward migration. This anarchistic scattering of the city into its local region would re-establish city/country reciprocity: what remained of the former would provide rural services and be fed by its rural hinterland through box schemes (regular supplies of boxes of produce direct from farm to consumer), farmers' markets and the like.

PRINCIPAL INFLUENCES ON RADICAL ECOTOPIANISM

As suggested above, radical ecotopia reflects influences from the 19th century and before, deriving particularly but not exclusively from socialist and anarchist utopianism. To environmentalists who see common ownership of land as a key issue (reflected in groups like *Reclaim the Streets* or *The Land is Ours* or the alternative communities movement), Gerrard Winstanley is a seminal figure. In *The Law of Freedom in a Platform, or True Magistracy Restored (1652)* Winstanley outlined a vision where land would be set free for the commoners. Environmentalists celebrate him particularly for his actions in assembling a community of commoners, the *Diggers*, who dug and planted the commons on George Hill, Walton, Surrey, in 1649. In their reluctance to envisage violent seizure of landowners' private property, and their hope that instead the landowners would voluntarily give up their lands and join them, these diggers foreshadowed an important aspect of green anarchist/social ecology strategy: that of prefiguring the desired society. This means that no strategy or approach (like violence, or social hierarchies) which would not feature in the utopia itself should be contemplated as part of the transitional struggle; this point became central to 19th century arguments between anarchists and Marxists.

A more paternalistic form of prefiguring might be seen in Robert Owen's utopian experiments. A businessman and mill owner between 1800 and 1812, thereafter he began to criticize contemporary society and economy. He reformed the conditions for his own mill workers at New Lanark, Scotland, then proposed and initiated self-sustaining communities of about 500–3000 people each, without private property, organized in rectangular units close to manufacturing plants and surrounded by intensive agriculture. Such exemplary communities were to lead to a cooperative socialism embracing the earth, formed by a new generation of rational beings.

Another utopian socialist, Charles Fourier (1772–1837), also strongly influences anarchist-feminist, communalist radical environmentalism. He envisaged phalansteries, communities of about 1700 people, as basic social units, with no overarching state regulation. In them, creative talents were expanded, meals and child-care were communal, and industrial armies carried out environmental projects. Traditional family relationships were dissolved and replaced by a wide spectrum of sexual relationships. The phalansteries reflected Fourier's view that all humans are born with their own innate instinctual drives, and utopia would be a place where each personality would be allowed to come out. Although capital, private property and wealth disparities remained, all were emotionally satisfied and spiritually rich. This suggests an essentially liberal utopia: the creation of an environment where all individuals could satisfy themselves. Fourier's

theme of enhanced life quality, perhaps compensating for lower material standards, features strongly in the seminal ecotopian visions of Schumacher (1973) and Goldsmith *et al.* (1972).

The 20th century's commune and back-to-the-land radical environmentalism (Pepper, 1991) has many links and resonances with similar 19th century alternative communities (Hardy, 1979, and Gould, 1988). Two of the strongest influences on them have been Peter Kropotkin and William Morris. O'Sullivan (1990) considers that Morris applied Marxism ••• to provide radical environmentalists with a document setting out many of their basic ideas in plain English. This includes voluntary simplicity; rejecting the false material wants and sprawling, ugly, polluting developments engendered by capitalism in favor of ••• the simple joys of the lovely earth ••• (Morris, 1887), and fellowship. He demonstrated his eco-socialist credentials by identifying commercialism and commodification under capitalism as the source of nature's impoverishment. Unlike deep ecologists, he did not oppose the fruits of industry *per se*, particularly organized in small workshops as craft production, nor did he abhor any change made to nature by humans. He saw a place for machines, in doing any unpleasurable work: again a theme in much modern ecotopianism, as seen, for instance, in the post-industrial utopia of Andre Gorz (Frankel, 1987). Morris also inveighed against pollution, urbanization of the countryside by mass housing and alienation of the laborer from his/her creativity, and consumerism. In *News from Nowhere*, there is no private property as a right, hence no hierarchy based on it, and little crime, except for that based on sexual passions. *Nowhere*, say the Manuels, goes alongside Edward Bellamy's Fourierist *Looking Backward 2000- 1887 (1888)* in a tradition of nostalgic socialist utopias which bypass the dynamism of industrial-scientific modern civilization. Their visions represent genteel socialism; non-threatening to Victorian capitalism (although Morris savagely attacked capitalism) and therefore open to the charge of utopianism in the Marxist sense.

Morris' vision is close to anarchism, and for Kropotkin (1892, 1899) anarchism would lead to true *commune*ism: the free association of producers without class division, wage slavery or even money. He initially conceived of his ideal communes as a specific spatial form (based on the Russian *mir*), but later, like Marx, he saw them less specifically as groupings of individuals with mutual interests in thousands of towns and villages. His picture of an ideal communist landscape is close in detail to that of the IM, and his principle of mutual aid as a key evolutionary law heavily infuses both *social ecology* and (paradoxically) *deep ecology* and *new ageism*. Fotopoulos's (1997) inclusive democracy echoes Kropotkin in many respects, although Fotopoulos, a disciple of Murray Bookchin's social ecology, does not, like many eco-anarchists, fall prey to utopianism in underestimating the immense power of capital to resist challenges to its self-perpetuating exigencies.

Much radical ecotopianism (bioregionalism, deep ecology and the new ageism into which this can merge) shows anarchistic leanings in its visions, but nonetheless lacks anarchism's materialist, socialist perspective as the basis of such visions. Rather, it is idealistic, and here two 20th century utopians seem particularly influential, Teilhard de Chardin and Aldous Huxley. Callenbach's *Ecotopia* (1978) closely resembles Huxley's *Island* (1962). The latter was a curtain raiser to 1960s' and 1970s' idealism and its rejection of consumer materialism, conformity, alienation and the perceived dangers of globalization and science allied to capitalism, such as large-scale development, nuclear war/power, pollution and waste and overpopulation (Huxley figured on the sleeve of the Beatles' *Sergeant Pepper* album).

Huxley's remedies for these evils, and the basis of his utopia, draw particularly on traditions associated with Eastern mysticism and the passive and pragmatic praxis they foster, and on the imagined liberating power of drugs and sexual freedom. His utopians achieve nirvana on an island paradise surrounded by global threats like oil exploration or the terrifying increase in China's population, by a combination of tantrik yoga, coitus suspendus, meditation, trance, autosuggestion and awareness-enhancing drugs, all mixed in with scientific enlightenment, particularly in the application of biological and ecological principles. His utopians avoid the pitfalls of wider society by virtue of the right people being intelligent at the right moment and they feel no need for things bad and thin and boring', such as speedboats or television, wars, revolutions, revivals or political slogans. This all resonates with that strain in environmentalism and other new social movements that emphasizes the power of reason and right thinking, answering perhaps to the angst of middle-class Western intellectuals, but being highly utopian in the sense of eschewing the realities of class politics based on the economic nature of capitalist society.

Teilhard de Chardin's *Phenomenon of Man* (originally written in 1947) is one of a complex of influences on idealistic radical ecotopianism; a perspective suffusing deep ecology and new age tendencies that see evolution towards a higher state of consciousness as the key to ecological salvation. These influences include Eastern and Western mysticism, and certain interpretations of 20th century science by such writers as Capra, Sheldrake, Bohm, etc. They are competently synthesized in Peter Russell's *Awakening Earth* (1991). The starting point is with the evolution of Gaia (the earth as a living being) which is considered to be guided by design rather than Darwinian chance into new orders of complexity, diversity and connectivity (*see* Gaia Hypothesis, Volume 5). This holistic, organic, monist and optimistic evolutionary perspective embraces

de Chardin s theology, envisioning Earth s becoming a social super-organism. It would comprise diverse but interdependent individuals and societies, coalescing in their thoughts and ideas through the power of love and the growing density of global communications. Eventually billions of individuals form a single inter-thinking group or *noosphere* (*see* **Noosphere**, Volume 5). This is a realm of consciousness which has evolved from material living matter (biosphere), that in turn evolved from non-living matter (geosphere). Eventually all three spheres are to become an organic unity. This euchronia will be *point Omega*, when Gaia will have become one supermind. Beyond this, Gaia might merge into a Gaia eld: a galactic superorganism.

Such a conceptual scheme loosely follows Hegel s view of history as a process of emerging world spirit. The noosphere is a universal belt of psycho-social forces that has evolved, not smoothly, but in a series of leaps in response to environmental crises at different stages of earth s history. The Manuels note that for all the science (anthropology, biology) buttressing this schema, it can only be looked on as a dream of reason. The speci cally Christian element in de Chardin has not, on the whole, impacted on modern ecotopianism, although van der Weyer s *Wickwyn* (1986) is a rare exception.

However, feminist utopianism has been more in uential. The society of *Ecotopia*, for instance, is almost ruthlessly feminist, while Capra s New Ageist *Turning Point* (1982) makes feminine values the key to impending ecotopia. Marge Piercey s *Woman on the Edge of Time* (1979) was much-loved by 1970s radical environmentalists. In it, the heroine jumps from contemporary society to an androgynous one where relationships and child care are rede ned, lifestyles are simple and natural, and there is, again, free love. The latter theme is recurrent in ecotopian IMs, because of its supposed contribution to heightened quality of life, and mitigation of the overpopulation problem. A more distant feminist utopia, Charlotte Perkins Gilman s *Herland* (1915), is usually ignored, though in it most things which environmentalists deplore (war, greed, money, stupidity) have been banished.

EM: REFORMIST ECOTOPIANISM?

Both left- and right-wing critics of free market liberalism have long detected a form of utopianism (in the derogatory sense) in the belief that the free market can bring a world of social justice, ecological sustainability and universal freedom (Gray, 1999). However, in the past two decades a new environmental discourse has emerged, which seems to give new impetus to this utopianism. Rejecting the pessimistic 1970s *Limits to Growth* perspective, this discourse embraces modernity, rationalization and internationalism, and is posited on continuing global marketization under capitalism. EM has become the mainstream, reformist organizing basis for new institutional procedures and perspectives to manage environmental problems.

As an approach to sustainable development, EM is seen by its most enthusiastic adherents as not merely a technocratic project to modify global modernization environmentally, but also as a form of institutional learning and cultural politics that heralds new ways of seeing and new opportunities for an emerging global civil society in the face of global economic forces and environmental problems.

EM discourse is complex, but its core features, which have become the basis of the environmental policies of Western states, are outlined in Table 2. Essentially, EM theory holds that a new phase of development is possible, and is happening, where capitalism (involving constant economic growth, technological development and the spread of consumerism through global marketization) and the goals of environmental conservation are reconcilable. Indeed, it sees environmental protection not as an impediment to capital accumulation but as a potential source of further accumulation; economic bene ts and competitive advantage being said to accrue from preserving genetic diversity and from anticipatory environmental protection, rather than paying out to clean up a mess. In this positive-sum game, technological and managerial experts, business and industry all become key actors in ful lling the environmental agenda, rather than its enemy, as environmentalists often suspect.

As an approach to sustainable development, EM clearly ts well with capitalist ideology and could be regarded as a form of social democracy without the big stick; for while the state legislates for EM s policy principles, in the contemporary ideological climate of *laissez-faire*, its role becomes contextual and steering, rather than *dirigiste* as in post-war Europe. For left-leaning environmentalists, particularly, however, EM represents a form of environmental utopianism in the Marxist sense, essentially because it envisages widespread new behaviors that would in reality serve as a brake or impediment on the operation of capitalist economic forces. Therefore, its principles and assumptions are bound to be unrealistic.

For instance, EM proposes that conventional economic growth and environmental protection are compatible; yet in reality economic growth leads today to global warming, rapid loss of species diversity and other undesirable effects. It assumes that rms will embrace anticipatory environmental technology because of its long-term profitability, but in fact most Western rms still opt for the quicker pro ts offered by end-of-pipe technologies (or by simply evading environmental standards). In any case it is unrealistic to assume that anticipatory technology can signi cantly lower environmental degradation in a growth economy, since gains from such technologies (e.g., catalytic converters) are more than offset by growing consumption (e.g., more cars and road-kilometers).

Table 2 Features of EM – Ecological Modernization[a]

EM's Realms (Hajer)
(1) New policy-making principles: e.g., from react and cure to anticipate and prevent; integrated pollution abatement; integrating environmental concerns into all ministries; techniques allowing firms to integrate environment into cost-risk calculations, such as polluter pays, cost-benefit analysis, risk analysis, precautionary principle, tradable pollution rights, pollution charges and taxes
(2) A new role for science in policy-making, especially ecological systems science. Experts take a central role
(3) Environment protection seen as a source of growth: low- and non-wasteful anticipatory technologies generate profits
(4) Nature reconceptualized: a public rather than a free good, so efficiency involves internalizing environmental costs
(5) Burden of proof reassigned: to the suspected polluter, not the damaged party
(6) Policy-making opened up: new participation and partnerships, e.g., between business and non-government organizations. Voluntary agreements rather than command and control regulation are encouraged
Weak EM Discourse Includes (Dryzek)
Anticipating unwanted outcomes of production/consumption, through systems approaches
Instrumental view of nature as provider of resources and services
Continued existence of capitalist political economy
Reassurances about continuing modernization, growth, progress
Weak EM Discourse Excludes (Dryzek)
Consideration of: limits to growth; Third World development paths; international environmental footprints of industrial development; a non-instrumental view of nature; alternatives to capitalist political economy
Preoccupation with equity and environmental justice
Unfettered free market economics
Unrestrainedly optimistic view of growth and development.
Strong EM Discourse May Include (Christoff)
An international dimension
Non-western development approaches
Deeper changes in beliefs and morality
Elevating equity, futurity, ecological imperatives by comparison with narrow economic goals
Re-embedding society in community, region, ecosystems: limits to modernization

[a] *Sources:* Hajer (1995), Dryzek (1997), Christoff (1996).

Attitudinal change underpins EM theory, which envisages that firms will embrace the more holistic accounting and planning for longer time horizons which are necessary for sustainability. However, such changes are not at present widespread among, for instance, US and EU businesses, because they take most decisions from short-term, sector-specific perspectives, as must happen in the increasingly competitive global marketplace.

Hence the hope that capitalist institutions can or will significantly reform, to take on environmental sustainability, is pious. For this would require giving equal weight to economic and to environmental and social justice goals, so that economic and civil spheres would become compatible as in the social democratic agenda. But in the real world Western civil and social democratic politics are increasingly subordinated to global marketization's economic agenda. For to re-establish profit levels after the 1950s–1970s round of Keynesian welfare spending, capital has often resisted social justice and environmental goals. These goals usually represent unacceptable costs. Whereas the sustainability agenda requires evening up wealth distribution, and substantial social spending, capitalism's inevitable dynamic is to concentrate wealth (Fotopoulos, 1997). And EM contains other utopian, idealistic assumptions which would not bear close scrutiny, for instance that Western affluence could be universalized in an environmentally sustainable way, that trickle down economics work, or even that economic growth is a universal good.

On this account, then, it is not only young and starry-eyed idealists or iconoclastic intellectuals who indulge in environmental utopianism: establishment pillars do the same, though in a different way. This raises the question of whether utopianism is a good or bad thing. If everyone does it yet no environmental resolution is reached, perhaps the habit should be discouraged. However, the notion of futurity is a cornerstone of the sustainability debate, hence it would be utopian to envisage that utopianism could ever be avoided in that debate.

Post-normal Science

Jerome R Ravetz
Research Methods Consultancy Ltd., London, UK

Post-normal science is a new conception of the management of complex science-related issues (Funtowicz and Ravetz, 1992, 1993, 1994, 1999; Ravetz, 1999). It focuses on aspects of problem solving that tend to be neglected in traditional accounts of scienti c practice: uncertainty, value loading, and a plurality of legitimate perspectives. It provides a coherent explanation of the need for greater participation in science-policy processes, based on the new tasks of quality assurance in these problem areas.

It is a means of illuminating, explaining and then guiding innovative decision processes that are happening spontaneously all over the world. The management of complex natural systems as if they were simple scienti c exercises has brought us to our present mixture of triumph and peril. We are now witnessing the emergence of a new approach to problem-solving strategies in which the role of science, still essential, is now appreciated in its full context

of the complexity and uncertainty of natural systems and the relevance of human commitments and values.

INTRODUCTION

In the sorts of issue-driven science relating to global climate change, typically facts are uncertain, values in dispute, stakes high, and decisions urgent. The sound science that is frequently invoked as the requirement for rational policy decisions may be an unaffordable luxury. The traditional distinction between hard, objective scientific facts and soft, subjective value judgments is now inverted. All too often, we must make hard policy decisions where our only scientific inputs are irremediably soft. In these new circumstances, invoking truth as the goal of science is a diversion. A more relevant and robust guiding principle is quality, understood as a contextual property of scientific information.

Appropriate intellectual tools are required for these new tasks. A scientific methodology designed for controlled experimentation and abstract theory building can make effective use of a picture of reality that reduces complex phenomena to their simple, atomic elements. However, that is not best suited for the tasks of science-related policy today. The traditional normal scientific mind-set fosters expectations of regularity, simplicity and certainty in the phenomena and in our interventions. However, these can inhibit the growth of our understanding of the new problems and of appropriate methods for their solution.

These new problems are characteristic of complex systems. These are not merely complicated; they involve interrelated subsystems at a variety of scale levels and at a variety of sorts. Thus, we now know that every technology is embedded in its societal and natural contexts, and that nature itself is shaped by its interactions with humanity. In such complex systems, there can be no single privileged point of view for measurement, analysis and evaluation. Moreover, in these systems there is generally no hidden hand whereby selfish individual actions automatically benefit the wider societal and natural communities; hence there is no substitute for morality in the good conduct of our affairs. The phenomena of life, society, and now the environment, cannot be captured, nor their problems managed, by sciences which assume that the relevant systems are simple. In terms of such paradigms, they will always present anomalies and surprises. Post-normal science has been developed as the appropriate methodology for complex natural and social systems.

The term *post-normal* provides a contrast to two sorts of normality. One is the picture of research science as normally consisting of puzzle solving within the framework of an unquestioned and unquestionable paradigm, in the theory of Kuhn (1962). Another is the assumption that the policy context is still normal, in that such routine puzzle solving by experts provides an adequate knowledge base for decision making. The great lesson of recent years is that this assumption no longer holds. We may call it a post-modern rejection of grand narratives, or a green, not-in-my-back-yard (NIMBY) politics. Whatever its causes, we can no longer assume the presence of this sort of normality of the policy process, particularly in relation to global climate change. The frequent, almost ritualized calls for debate' on major policy questions of risks and the environment are an implicit recognition of their post-normal character.

In such novel contexts, there is a new role for natural science. The facts that are taught from the textbooks used in institutions are still necessary, but they are no longer sufficient. Contrary to the impression that the textbooks convey, in practice most problems have more than one plausible answer, and many have no well-defined scientific answer at all. Further, in the artificial world studied in academic science courses, it is strictly inconceivable that science-related problems could be tackled and solved except by deploying the accredited expertise. Practical techniques, which cannot be explained in principle by accepted science, are commonly dismissed as the products of blind tradition or of chance. When persons with no formal qualifications attempt to participate in the processes of innovation, evaluation or decision-making, their efforts have tended to be viewed with suspicion or scorn. Post-normal science provides a means for correcting this sort of mind-set.

POST-NORMAL SCIENCE

As a theory, post-normal science links epistemology (study of the grounds for knowledge) and policy, for its origins lie in the relations between those two domains. Its authors were concerned that the sciences devoted to solving risk and environmental problems (such as those in ecology and toxicology) are radically different from those that are instrumental in creating them (such as the applications of physics and molecular biology). In comparison to those traditional sciences, the policy-relevant sciences have enjoyed less prestige and funding, are less mature scientifically, and are more subject to external influences and constraints. By the criteria of the traditional philosophy of science, their results frequently fail to attain the status of sound science. It has been argued that they should, therefore, be rejected as evidence in policy debates; but a more appropriate conclusion would be that the philosophy of science needs recasting. Post-normal science provides a response to these crises of science and philosophy, by bringing facts and values into a unified conception of problem solving in these areas, and by replacing truth by quality as its core evaluative concept. Its principle of the plurality of legitimate perspectives on any problem leads to a focus on dialogue, and on mutual respect and learning, wherever possible.

Post-normal science comprises those inquiries that occur at the interfaces of science and policy where uncertainties and value-loadings are critical. It can be analyzed as a policy cycle including: policies, persons, procedures, products, and post-normal assessment; it also extends to the downstream phases of implementation and monitoring (Funtowicz *et al.*, 2000). Depending on the particular context, the task may be more like policy-related research, or science-related decision making, or creative technical-social innovation. In the case of global climate change, all three sorts are in play; the distinctions are never absolute, as the whole endeavor is a complex system.

Post-normal science can be located in relation to the more traditional problem-solving strategies by means of a diagram (see Figure 1). On it, we see two axes – systems uncertainties and decision stakes. When both aspects are small, we are in the realm of normal, safe applied science, where expertise is fully effective. When either is medium, then the application of routine techniques is not enough; skill, judgement, sometimes even courage are required. This is professional consultancy, with the examples of the surgeon or the senior engineer in mind. In such cases, the creative element in the problem is more an exercise in design than the discovery of facts. Our modern society depends on armies of applied scientists pushing forward the frontiers of knowledge and technique, with the professionals performing leading roles in technical and policy matters. In recent years we have learned that even the skills of professionals are not always adequate for the solution of science-related policy issues. When risks cannot be quantified, or when possible damage is irreversible, then we are out of the range of competence of traditional sorts of expertise and traditional problem-solving methodologies. This situation is represented on the diagram as the outer band, that of post-normal science. We notice that the band extends through the whole quadrant, right up to the region where systems uncertainties vanish. This feature reflects the fact that, if in some policy process the decision stakes are very high (as when an institution is seriously threatened by a proposed policy), then a defensive strategy will involve challenging every step of a scientific argument, even if the systems uncertainties are actually quite small.

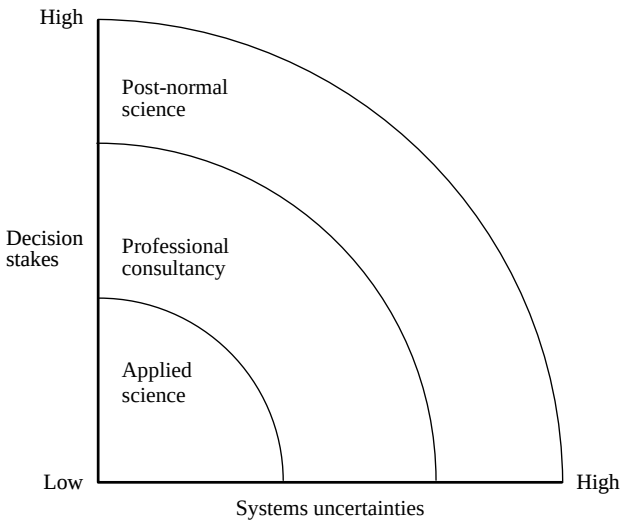

Figure 1 Post-normal science

The management of systems uncertainties through the involvement of decision stakes occurs even in routine science. Whatever the statistical test, there will always be errors: some true correlations will be rejected (Type I) and false ones will be accepted (Type II). A balance must, therefore, be struck between the error-costs of excess specificity and those of excess sensitivity, respectively; and that balance depends on the policy framework of the test. For example, if the problem is detecting possible harm from contaminants, it is better to err on the side of precaution and be more inclusive; a test designed around avoiding false positives could exclude potentially important information (Type I error), which could then remain permanently unknown. The well-known confidence level expresses this value-driven choice. Researchers do normally not assign it; rather they automatically apply the level that is standard for their field.

When a problem is recognized as post-normal, even the routine research exercises take on a new character. For the value-loadings and uncertainties are no longer managed automatically or unself-consciously. As they may be critical to the quality of the product in the policy context, they are the objects of critical scrutiny by researchers themselves as well as by their peers. Thus, normal science itself becomes post-normal, and is liberated from its traditional unreflective, dogmatic character.

The awareness of global climate change is well on the way to transforming all our conceptions of policy problems in the post-normal direction. For example, passenger transport had traditionally been seen as an essentially straightforward engineering problem of maximizing mobility, subject to the constraints of cost and safety. Now transport technologies and policies are strongly influenced by environmental considerations of many sorts. Moreover, the need to control the increase in private passenger transport depends directly on lifestyles. Together with the systematic uncertainties of global climate change, there are crucial decision stakes in conceptions of the good life, along with considerations of equity between peoples and generations. The entire population of passenger transport users effectively becomes an extended peer community; for the success of sustainable transport technologies will depend on the effectiveness of users' commitment to the values of the global environment.

EXTENSIONS OF THE PEER COMMUNITIES

There are now many initiatives, increasing in number and significance all the time, for involving wider circles of people in decision-making and implementation on environmental issues. The contribution of all the stakeholders in cases of post-normal science is not merely a matter of broader democratic participation. For these new problems are in many ways different from those of research science, professional practice, or industrial development. Each of those has its established means for quality-assurance of the products of the work, be they peer review, professional associations, or the market. However, for these new problems, the maintenance of quality depends on open dialogue amongst all those affected. This we call an extended peer community, consisting not merely of persons with some form or other of institutional accreditation, but rather of all those with a desire to participate in the resolution of the issue. Since this context of science is one involving policy, we might see this extension of peer communities as analogous to earlier extensions of the franchise in other fields, such as women's suffrage and trade union rights. This is not merely a matter of extensions of liberty; with post-normal science we can guide the extension of the accountability of governments (the foundation of modern democratic society) to include the institutions involved in the governance of science and technology.

Extended peer communities are already being created, in increasing numbers, either when the authorities cannot see a way forward, or when they know that without a broad base of consensus, no policy can succeed. They are called *citizens juries*, *focus groups*, *consensus conferences*, or any one of a great variety of other names; and their forms and powers are correspondingly varied. Nonetheless, they all have one important element in common: they assess the quality of policy proposals, including a scientific element, on the basis of their level of scientific comprehension combined with their knowledge of the ways of the world. Their verdicts all have some degree of moral force and hence political influence.

These extended peer communities will not necessarily be passive recipients of the materials provided by experts. They will also possess, or create, their own extended facts. These may include craft wisdom and community knowledge of places and their histories, as well as anecdotal evidence, neighborhood surveys, investigative journalism and leaked documents. Such extended peer communities have achieved enormous new scope and power through the Internet. Activists scattered among large cities or rainforests can engage in mutual education and coordinated activity, providing themselves with the means of engagement with global vested interests on less unequal terms than previously.

Along with the regulatory, evaluative function of extended peer communities, another function, even more intimately involved in the policy process, is springing up. The discovery is being made, again and again, particularly at the local level, that people not only care about their own environment but can also become quite ingenious and creative in finding practical, mixed social and technological means for its improvement. For local people can imagine solutions and reformulate problems in ways that the accredited experts, with the best will in the world, do not find normal. This is most important in the phases of policy-formation, and also in the implementation and monitoring of policies. Thus, in addition to extending the traditional processes of quality assessment, participants can enhance the quality of the problem-solving processes themselves. Even more than in environmental issues, numerous groups of patients and activists in the medical field have been demonstrating post-normal science at work.

Post-normal science belongs to a growing family of approaches to the understanding of the new predicaments of science and society. Beck (1992) has described the risk society and the development of sub-politics, effectively the extended peer communities. Wynne (1996) has contributed on extended facts and the need for extended peer review. Irwin (1995) has stressed the importance of the contribution of local communities and activists. Jasanoff (1998) has analyzed the effectively post-normal situation of science in the courtroom, and showed how citizens can exercise effective quality control there.

What we call science has undergone many changes over the centuries in its objects, methods and social functions. The previous century saw science rise to unimaginable achievements in knowledge, power and then destructiveness. With post-normal science we are characterizing the changes that will be necessary for our civilization to become sustainable, and thereby to survive.

Precautionary Principle

Tim O'Riordan
University of East Anglia, Norwich, UK

The precautionary principle emerged in Germany in the 1970s and has become a central plank in European Union environmental policy since the early 1980s. The precautionary principle as applied to environmental management is based on the idea of acting prudently in advance of full scienti c certainty, leaving room for ignorance in the use of resources, and placing the onus of proof on those who propose to change, to show that there will be no harm as a result of their proposed actions. In recent years the precautionary principle has moved from the realms of science and environmental management to the politics of risk, social responsibility, trade and protecting the well-being of the innocent and vulnerable.

The attraction of precaution lies in the aphorisms *a stitch in time saves nine*, and *better safe than sorry*. Its significance as a guiding principle in environmental science lies in its challenge to conventional science, its preference for the victim of potential environmental abuse, and its shift in the nature of valuation techniques in favor of a more communitarian democracy. The precautionary principle will prevail because the political mood of environmentalism is moving towards sustainability, because a more inclusive stakeholder involvement in environmental decision taking is becoming the vogue, because scenarios about possible future environmental states are much more readily available due to huge computing power and the internet, and because an anxious citizenry is beginning to take the management of environmental risk into its own hands.

The precautionary principle emerged from German law in the late 1970s as the *vorsorgeprinzip*. This was taken to mean acting with care and with anticipation, in order to prevent avoidable harmful effects to humans and the environment. The *vorsorgeprinzip* was promoted by the Brandt Government as a justification for state intervention in the economy, for forward planning, and for the encouragement of clean technology. It was thus a justification for the aggressive intervention of the state in land use management and in the direction of investment into export-earning technological advance, pushed by tough and pro-active environmental regulation.

The basic principles of the precautionary principle are:

- *Thoughtful action in advance of scienti c proof*: most environmental future states cannot be forecast with any certainty. There are neither the data nor the modeling accuracy to do the job. Where the burden of evidence falls on the side of possible harm, the precautionary principle is invoked, even though taking action will cost money.
- *Leaving ecological space*: because we cannot be sure how tolerant ecosystems are to human intervention, it is necessary to leave ecological space as a buffer against our ignorance. Sometimes this practice is placed into law, as, for example, is the case in South Africa. There, the 1998 National Water Act provides for an entitlement of water for nature as an act of precaution. Human users, beyond allocation for essential needs, have to come second. This general principle, notably as regards water, will become more widespread.
- *Care in management*: because it is not possible to predict all possible consequences of any environmental management decision, it is necessary to focus on the vulnerable and the most likely losers of a possible course of action. This max-min' strategy of risk management is a feature of empowerment in a modern democracy, transferring an element of trust and respect to the politically most marginal.
- *Shifting the burden of proof*: possibly the most dramatic outcome is the legal and political shift of the burden of proof away from those likely to be harmed by a possible course of action, towards those who plan to change the *status quo*. In the past, all that a developer had to do was to show that no likelihood of unreasonable harm would ensue for a particular course of action. With the

precautionary principle, the balance of proof falls on the developer to show that particular interests will not be harmed at all.

The precautionary principle is brought into environmental management for seven reasons:

- *There is an active civic science*: citizens want to be directly involved in providing the valuation and validation of scientific data and findings. The future of genetically modified organisms in foodstuff, for instance, is no longer a purely scientific matter. The more citizens groups are involved, the more the precautionary principle will be applied.
- *The scope for collapse of vulnerable ecosystems is real*: the scare stories over the losses of biodiversity, of tropical forest removal and of coral reef bleaching have caused many active citizens to believe that we simply cannot know enough about the precursors to ecological collapse. Indeed, it is difficult for ecologists to come up with indicator conditions in species that provide a satisfactory basis for predetermining system collapse. This is why a more participatory ecological science is required.
- *Dislocation at a local level accumulates to seriously adverse global consequences*: precaution is necessary to stop the global commons from being degraded by millions or even billions of micro-level individual actions; no one individual has any incentive, other than altruism, to control his/her consumer behavior. In this sense, precaution is both proactively regulatory, and also personally educative, for it creates a wish in both the producer of products and services, and in the consumer, for a sense of responsibility for planetary stewardship.
- *Vulnerable groups are championed by citizens' justice organizations*: the rise of the eco-justice movement has been stimulated by civil rights groups, and by the growing evidence that environmental harm is disproportionately directed towards the poor, the vulnerable and the politically marginalized. The act of precaution is now being used to create a citizen's right to a healthy environment. Again, this procedure places a political bias on disadvantaged groups to be empowered. How far this can effectively be implemented remains to be seen.
- *Business is worrying about corporate reputation*: the scares over genetically modified organisms in food, or infectious salmon anaemia in fish-farmed salmon have seriously damaged public trust in corporations promoting such practices. This, in turn, has led to a popular resistance to eat food from fields or fish farms experiencing these modifications: in various recent polls, over 54% of British consumers will consciously avoid such foodstuffs. Therefore, businesses embarking on environmental audits and social responsibility programs also expose themselves to applying the precautionary principle in a more aggressive manner.
- *Regulation is more transparent*: the role of the regulator has been made more difficult due to the rise of the Internet, and to the scrutiny of intervener consumer and environmental organizations. No longer is regulation a secretive and private matter. Increasingly, all regulatory actions have to be open and accountable to an active citizenry that is looking to the precautionary principle to guide the levels of environmental safeguards being set for all classes of social groupings. Like science, regulation is a more participatory activity, and hence values and aspirations of various interested parties are now a legitimate part of standard setting and permitting.
- *Direct action is more ubiquitous*: direct action, involving illegal protest, over administrative and commercial acts that no longer are tolerated by angry citizens organizations, is not new. But these days it has adopted a greater potency due to the variety of opportunities available, the inquisitiveness of the media, the tolerance of the politicians, and the intolerances of the police. An additional factor is the general feeling that playing by the rules will not result in adequate political response. Direct action is a recognition that formal democracy is ineffective. Informal democracy is seen as a lever of citizen power. In these days of precaution and civic activism, direct action becomes increasingly attractive and innovative (*see* Public-driven Response to Global Environmental Change, Volume 4).

For precaution to work properly, however, there needs to be a change in both science and law beyond what is occurring today. The incorporation of soft values relating to being more in tune with nature and more sensitive to the legitimate aspirations of all others is a matter that separates interdisciplinary science as currently practiced from post-normal science (*see* Post-normal Science, Volume 5). The science of including feelings, of introducing trust, and of nurturing sensitivity for the interests of others is not quite born.

Nor are the joint property rights of stewardship fully developed. This is the extension of property rights to include the well-being of ecosystem functioning and social connectedness in all aspects of managing land, natural resources, and the commons. There is a part-way stage in this legal revolution in the application of the *public trust doctrine*. This states that any avoidable damage to the interests of others must be recognized and compensated, and also that the ability of those likely to be adversely affected, should be enhanced by training and mediation for empowerment.

This is the widening context of the application of the precautionary principle in contemporary environmental management. It is opening windows on science, law, politics,

regulation and moral norms. Precaution continues to be a truly transformationist concept.

Property Rights and Regimes

Bonnie McCay

Rutgers, The State University of New Jersey, New Brunswick, NJ, USA

Property rights are fundamental institutions of all societies. They are the formal and informal rules about how people relate to things and places they value. Property rights may be defined in terms of who holds rights whether persons (individuals, business firms and other units with the legal identity of persons), organizations, governments, or loosely defined latent groups (Olson, 1965) such as the public or all humankind. Thus, we talk of individual property, communal property, government property, and public property (as for example in the Swedish allmennsretten). Property may also be understood in terms of the kinds of rights people hold, including degrees of exclusivity and inclusivity. Private property is at the exclusive end of this continuum, and public property, implying the right not to be excluded (Macpherson, 1978), is at the inclusive end.

The language of property regimes is often used in discussions of environmental problems. Property regimes are systems of governance or regulation that differ from each other in terms of which property rights are most prevalent or controlling. Many writers use terms similar to open access, common property, state property, and private property when talking about different systems of resource management (e.g., Bromley and Cernea, 1989; Feeny et al., *1990). Although there are problems with this scheme (McCay, 1996) and other ways to label the systems (e.g., Ostrom* et al., *1999), it provides a useful framework for discussing property regimes and the environment.*

In trying to understand how property rights affect the ways people relate to their environments, we specify just what kinds of rights are held and by whom, and examine how particular property rights are nested within larger systems of rights and duties as well as their embeddedness in cultural and political traditions. In the Anglo American legal tradition, property is often described in terms of bundles of rights, i.e., distinct though interrelated rights (Rose, 1994). For example, exclusive rights of access or use, rights to income from the property, rights to change attributes of the property, the right to gift or will it to one s heirs, and the right to sell or lease it may or may not be part of a particular bundle of rights or ownership. The owner may have some sticks in the bundle of rights but not all, and ownership can be overlapping and complementary. For example, in a housing condominium, the owner of an apartment or townhouse holds exclusive rights to live in and decorate the interior but has ownership in common with others of the exterior of the building and perhaps the grounds. He/she may hold the right to vote on decisions about management of the common property but is required to abide by the decision rules. His/her right to transfer ownership to someone else may or may not be subject to approval of an association of co-owners. The condominium is in a larger community, which subjects it to taxation and to zoning and other regulations, and so forth.

An open access system is one where there are few if any barriers to entry or use and no regulation of the activities of resource users; this is the condition meant by commons in the well-known essay *The Tragedy of the Commons* (Hardin, 1968) (*see* **Commons, Tragedy of the**, Volume 5). It is also one of the powerful assumptions of the formal models used in economics to depict the tendency for resource users to over-exploit resources (Gordon, 1954; Scott, 1979).

As long as access is open, there are no incentives for resource users to take care of the resource because of the temptation to free-ride on the efforts of others. An open access system is also one where present users cannot really control the behavior of others, who can come and go as they please, reducing the benefits of individuals' efforts to conserve. Open access is accompanied by other special assumptions, such as the self-interested, profit-maximizing individual and the paradoxical assumptions of complete information on the one hand and lack of communication on the other (McCay and Acheson, 1987; Feeny *et al.*, 1996). Recognition of the limitations of these and other assumptions lies behind skepticism about the universal appropriateness of prescriptions that follow from the open access model: convert the system to either a private property or a state property (governance) regime.

Private property and state property are the regimes usually identified as solutions to the tragedy of the open access commons. Here, state property does not refer to the things and places owned exclusively by a government (like a defense department's munitions depot) but rather to government's ownership of the right and means of regulating or governing the use and distribution of common or public resources as well as ownership of lands in trust for the public. It is better to refer to it as state governance (Berkes and Feeny, 1990; McCay, 1996). According to economic property rights theory, over-exploitation and economic difficulties created by open access regimes require the strong arm of state governance because users of shared property cannot be counted upon to regulate themselves. Among the problems with this conclusion is over-reliance on the state as a homogeneous, benevolent, all-knowing entity interested in and capable of acting on behalf of long-term as well as short-term interests. This view of the state or its regulatory authorities is implicit in economic property rights theory, but it rarely fits the evidence of historical and contemporary reality (Feeny *et al.*, 1996).

Even better, according to the theory, is reliance on private property (especially in the liberal notion of exclusive ownership of most or all of the sticks in the bundle of rights). The idea is that private owners will have the incentives that public users lack to properly manage resources. However, the argument that private property is superior policy is faulty on logical as well as empirical grounds (Ellickson, 1993; Christman, 1994). It also rings false in theoretical circles. Under conditions of high rates of discounting the future and low rates of reproduction of the resource, a private owner is no less likely than a common user to over-exploit the resource (Clark, 1973). Moreover, some resources cannot easily be treated as private property: their physical features may be such that it is difficult to exclude others from them, and even if one did exclude others from part of them, what one does may affect the benefits that another realizes. They are common pool resources; any property rights asserted over them are necessarily imperfect, and the result is market failure. Hence, there must be alternatives.

The metaphor of an open access tragedy and the prescriptions of privatization and government intervention are often used in discussing environmental problems. They are linked to policy debates between command and control and market-based environmental control measures. Command and control refers to state governance (borrowing from criticisms of the socialist and communist governance systems). Market-based environmental protection refers to the creation of quasi-private property rights within the framework of state governance in order to improve compliance and efficiency while achieving social goals. Examples include air pollution systems that use tradable emission permits and fisheries management systems using transferable individual quotas. Tradable emissions permits were used to phase out lead in gasoline and reduce sulfur emissions in the US, providing greater flexibility and thereby economizing (Hahn and Hester, 1989). Similar programs have been used to eliminate ozone-depleting gases and to control acid rain and tropospheric ozone in the US. Canada, Chile, and Germany are other countries using tradable permits (Tietenberg, 1995, 1998) (*see* Tradable Permits for Greenhouse Gases, Volume 4; Tradable Permits for Limiting Stratospheric Ozone Depletion, Volume 4; Tradable Permits for Sulfur Emission Reductions, Volume 4; Transferable Fisheries Quotas (TFQs), Volume 4; Quotas in International Environmental Negotiations, Volume 4).

In marine fisheries, annual quotas for how much may be caught without jeopardizing the sustainability of a fish stock may be allocated to individual participants, just as pollution emission rights are allocated to individual polluting firms after a permissible level is established in relation to legal and scientific criteria (National Research Council, 1999). A recent review of these individual fishery quota (IFQ) systems in the US, Canada, Iceland, and New Zealand highlights the many issues, costs, and benefits of privatizing rights to shares of a quota. Reviews such as this have led to consideration of how to balance the benefits of market-based allocations with the concerns of individuals, communities, and industries for the future of their jobs and investments, as well as the broader societal concern with sustainable development. This effort includes attempts to develop market-based instruments that increase the conservation incentives for holders of exclusive rights while dealing with problems of equity, stewardship, and resilience (ability to adapt to changes in the environment) (Young and McCay, 1995).

Largely neglected thus far in the policy deliberations of major countries is the role of common property governance. Property rights scholars now object to the use of the term commons as equivalent to open access because it ignores the historic and contemporary importance of institutions in

which people share rights of access and use and have some degree of regulation of their activities on the commons (Ciriacy-Wantrup and Bishop, 1975; Cox, 1985; McCay and Acheson, 1987; Hanna, 1990; Bromley, 1992). Experimental and comparative case studies have helped create an understanding of the internal and external conditions under which common property institutions develop and are sustainable as well as those under which they falter (Ostrom, 1990; McKean, 1992).

Examples of external and internal conditions that promote community success in commons management include the ability to clearly define and regulate entry to membership in the community. It is also important to have autonomy from outside governance, to enable local experimentation and adaptation to local conditions, but to obtain enough legitimization and other assistance from the outside to help members of a community monitor the conditions of the resources or environments about which they care, so that they have reliable and accurate knowledge about those conditions. Local communities may also need external help to deal with spillover effects among communities. Critical internal factors include the ability to achieve broad participation in decision-making and implementation even where there are significant differences among participants; to create consensus about the fairness and rightness of the regulations; and the ability to monitor behavior and outcomes and to enforce and appropriately modify rules and regulations. Some factors pertain to the features of the environment, such as whether the flow of resources or risks from it is predictable or unpredictable and how abundant those resources or dangerous those risks are (cf. Ostrom *et al.*, 1999). Ironically, external conditions that promote community failure in these and other regards include the perverse effects of the very forces promoted as solutions to commons problems: intervention of the state and the workings of markets (McCay and Jentoft, 1998).

An emphasis on common property governance leads to three questions for broader understanding of global environmental change. The first is how to develop effective community-based systems for environmental protection and management. Community-based management has become a priority for international lending agencies and, even more so, non-governmental organizations in many industrialized and less-developed countries. However, it is not easy to implement, particularly where communities and the environmental resources with which they interact have been disrupted by warfare, migration, and disease, as well as long histories of subjugation and control by colonial powers, corrupt or unreliable political regimes, and economic restructuring due to international debt burdens. As much to the point is the poorly defined status of community property rights in most nations.

Second is the question of what can be learned from community-level studies that can inform efforts to improve international-level environmental regimes, the scaling up challenge. Important work is being done in this regard by students of international environmental regimes (Young, 1999, 1997; Haas *et al.*, 1993). Beyond the borders and boundaries of national jurisdiction, one might presuppose open access, which is supported by the international legal and political framework accepting the nation–state as the top level of sovereignty. Consequently, by law it is up to the nation–state to regulate uses of natural resources and their environments even in international realms, including the oceans (beyond 200 nautical miles from coastal borders) and the atmosphere and true frontiers (i.e., Antarctica). The international regimes that have arisen have some of the features of community-based common property regimes, such as reliance on trust which is built upon prior experience and interaction. Boundaries are necessarily more porous and enforcement a significant problem, as is shown in Canada's actions in the mid-1990s to protect straddling stocks of fish which migrate between Canadian and international waters. But communities do develop, based on shared knowledge about scientific findings as well as commitments to international solutions to environmental problems. More work needs to be done on whether or not the communities which evolve in these international diplomacy and scientific settings, so-called epistemic communities (Young, 1994), are appropriate structures for the development of common property regimes, or whether they will remain weakened versions of separate – but equal – state governance regimes.

The third question is how the interests and concerns of communities can be better incorporated into the policies and actions of governments and of private persons and firms. This refers to old but still relevant questions concerning social impacts and participatory management (also known as democracy in action). These are questions about the role of civic society in shaping the world, the earth, and the globe for tomorrow. All property regimes for dealing with environmental problems require viable civic institutions.

Religion and Ecology in the Abrahamic Faiths

Rosemary Ruether
Garrett-Evangelical Theological Seminary, Evanston, IL, USA

All the major world religions have been responding to the ecological crisis in recent decades by examining their traditions for resources to promote a more sustainable relationship between humanity and nature. In 1998 1999 the Center for World Religions at Harvard University assembled ten global conferences on the relationship of ecology and ten different world religions. Major gatherings of scholars examined the resources for ecological spirituality and ethics in Buddhism, Confucianism, Shinto, Hinduism, Judaism, Christianity and Islam, Jainism and Taoism, and indigenous traditions. Papers from these conferences are being published as books. This series will provide a major library on the issues of ecology and world religion.

This article focuses on the three Abrahamic faiths, Judaism, Christianity and Islam. These faiths differ from Asian or indigenous religions in being not only monotheistic, but also imaging God solely as male. They are also marked by a strong separation between God as Creator and Nature as Creation. These faiths were challenged some years ago when the historian of science, Lynn White, wrote a widely read article in which he charged that the biblical mandate in Genesis 1:28, giving humanity absolute dominion over the earth, was the major religious root of the ecological crisis (White, 1967). In this text God is represented as saying to the newly created humans, fill the earth and subdue it, and have dominion over the fish of the sea and over the birds of the air and over every living thing that moves upon the earth . The language used in this verse suggests a power relationship of military conquest and forcible subjugation by humans of the rest of nature.

Both Jewish and Christian scriptural and theological scholars have been engaged in refuting White s claims that the Bible as a whole mandates such an unlimited and exploitative relationship to nature as is suggested in *Genesis*. A number of Muslim writers have also taken up this issue of the view of human power over nature as re ected in the Qur an, itself rooted in Hebrew Scripture.

Jewish scholar Eric Katz has pointed out that *Genesis* 1:28 can hardly mean absolute and unlimited power over nature since the very next verse, Genesis 1:29, mandates a vegetarian diet for humans and animals. It is only after the corruption of society and God s punishment of humanity by the ood, that humans are allowed to kill and eat animals. But this is clearly seen as a fall from an original ideal of a more peaceful world (Genesis 9:2 4), but even then there are limits to human use of animals. Animals are to be killed in such a way as not to eat the blood.

Ismar Schorsch, writing on the Jewish view of ecology, suggests that the picture of humanity in relation to nature found in Genesis 2 3 is more the normative one for the

Bible. Here humans are seen as created from the topsoil of the earth, and as having affinity with the land from which they are made. They are not allowed to eat anything they wish in the garden. When they violate this commandment and seek to seize the fruit of the tree of knowledge of good and evil, human status degenerates. They are made to till the earth by the sweat of their brow. Hard struggle to survive, not lordly dominion, is the actual lot of humans in history.

For both writers the basic view of humans and nature in the Hebrew Bible is rooted in a theocratic understanding of creation. God is the creator of nature, and God alone has sovereignty over it. In the words of Psalm 24: The earth is the Lord's and the fullness thereof, the world and those who dwell therein . The laws of Jubilee clearly state that God remains the owner of the earth: The land shall not be sold in perpetuity, for all the land is Mine, because you are strangers and sojourners before Me (Lev. 25:23). Humans have only delegated authority over the earth, as representatives or stewards of God who remains its owner. This role of stewardship mandates both responsible care and limited use of the earth.

This view of the God–human–nature relationship is reflected throughout Hebrew law, both in the Bible and in its talmudic development. The Hebrew Bible reflects an agricultural people, and many of the divine commandments express a basic concern to limit human use of the land, its plants and animals, and to prevent abuse. The raising of goats and sheep is limited because of their excessive impact on the land. Grape vines and live trees are not to be used in sacrifice, because they are needed for food. Open land is to be preserved around towns. Trees are not to be cut down in war. Nothing is to be wantonly destroyed. Places of human habitation are to be separated from places of work that create smoke, dust and smells. Human sewage should be buried.

Perhaps the central Jewish ethic of ecological sustainability is found in the sabbatical legislation. This legislation proscribes a series of periodic cycles, seven days, seven years and seven times seven years, the ultimate cycle of the Jubilee.

Work is limited to a six-day period, following the example of God in creating the world. On the seventh day, not only the farmer, but his human and animal work force are to rest: On the seventh day you shall rest, so that your ox and your donkey may have relief, and your home born slave and resident alien may be refreshed (Ex. 23:12).

In the 7-year cycle, care is given to the poor, the wild animals and the renewal of the land:

> For six years you shall sow your land and gather its yield; but the seventh year you shall let it rest and lie fallow, so that the poor of your people shall eat and what they leave, the wild animals may eat. You shall do the same with the vineyard and your olive orchard.
>
> (Ex. 23:10–11)

Hebrew slaves are to be set free without debt in the seventh year (Ex. 21.2). Levitical laws mention slaves, hired laborers and animals allowed to rest during the sabbatical year, living off the untilled land along with the farmer (Lev. 25:6–7).

The Jubilee year, that occurs every fifty years, is to see a yet more profound restoration of the rights of all humans with respect to the land and animals. Those who have fallen into slavery are to be released. The debts that have accumulated during the past forty-nine years are to be liquidated. The earth is to lie fallow, human workers, animals and land given rest. Land confiscated due to debts is to be restored. The vision here is a general righting of relations in order not to endlessly extend a system in which the rich get richer and the poor get poorer, a society of a few wealthy, slave-owning landlords and many slaves or indebted workers. Justice and sustainability are to be periodically restored through a cyclical permanent revolution .

Hebrew Scripture also makes clear that humans are not the mediators of all relations between God and nature. God has many direct relations with other creatures, animals and planetary spheres, which humans know not of. The smallness and limits of the human arena of knowledge and control is emphasized in texts such as the book of Job. God rebukes human arrogance with such words as:

> Where were you when I laid the foundations of the earth, when the morning stars sang together and all the heavenly beings shouted for joy? ••• Can you hunt the prey for the lion or satisfy the appetite of the young lions? ••• Is it by your wisdom that the hawk soars ••• is it at your command that the eagle mounts up and makes its nest on high.
>
> (Job. 38–39)

In Hebrew Scripture the non-human world is not dead matter . It is animate and has its own lively relationship with God, independent of humans. God is present throughout the natural world. Both natural blessings and disasters reflect God's presence, both in blessing and in judgment. The non-human world understands this, better than humans.

> But ask the animals and they will teach you; the birds of the air and they will tell you; ask the plants of the earth, and they will teach you, the fish of the sea will declare to you. Who among all these does not know that the hand of the Lord has done this? In his hand is the life of every living thing, and the breath of every human being.
>
> (Job. 12:7–10)

The Hebrew worldview neither sacralizes nature as divine in itself, nor secularizes it. Humans have an important, but limited role. Reality is theocentric, in a way that relativizes and limits human power and places all things under divine sovereignty, as its ultimate owner and continuing source of life. God's relation to each creature is personal and direct, and each creature responds to its creator with praise and joy.

The Islamic view of the God–nature–human relation has some differences from that of Hebrew Scripture, but it is rooted in the same basic understanding. Muslim tradition is concerned to emphasize God's absolute unity (against the Christian Trinity) and sovereignty over all creation. Islam rejected the Jewish tradition that God rested on the seventh day, after creating the world, since that seemed to suggest that God was finite, becoming weary and needing rest. Creation is not something that happened in a primordial moment and then was completed. Rather God continually creates. All creation, and everything in it, is dependent on God for its existence from moment to moment.

There is less emphasis on the limits of human rule, although the ban on pork and wine suggests that humans do not just have all of nature at hand for their consumption. Humans are exalted as the vice-regents of God. As such they are superior not only to the animals, but even the spiritual beings. The angels bow before the wonder of God's supreme creation, the Human. Yet the Qur'an (Koran) also sees all creation, and not just humans, as praising and giving thanks to God. All natural things are to be respected as fellow creatures.

The idea of human vice-regency itself implies that humans are not the ultimate owners of the Earth. The Islamic view, like the Hebrew, is theocratic. God alone is sovereign; humans hold a delegated power over the Earth and are accountable to God for their tenure. They will be ultimately judged as to how well or badly they exercised this stewardship. Thus the eschatological (end of time) emphasis in Islam on the coming judgment is not understood as an escape from the earth that allows humans to ignore its wellbeing. Rather it is the ultimate accounting before God, by which they will be held responsible for their stewardship.

The idea that God creates the world from moment to moment, that all things lie directly in the hand of God, also lends itself, particularly in the poetic and sapiential (wisdom) traditions of Islam, to a mystical sense of all created things as the signs of God's presence. Nature lies within God's surrounding presence. In that sense it is God who is the ultimate environment that surrounds and encompasses humanity, as in the Quranic verse: But to God belongs all things in the heavens and the earth, and he it is who encompasses (muhit) all things (IV:126). Although nature is not sacred in itself, it is sacred, or one might say sacramental, as signs and pointers to God, who is present in every moment as its sustaining creator.

As Islamic writer, Seyyed Hossein Nasr (*see* Nasr, Seyyed Hossein, Volume 5) puts it:

> In reality, humans are immersed in the Divine Muhit (encompassing environment) and are only unaware of it because of their own forgetfulness and negligence. ••• To remember God is to see Him everywhere and to experience His reality as al-Muhit. The environmental crisis may in fact be said to have been caused by the human refusal to see God as the real environment which surrounds and nourishes our life.

The Islamic tradition of sacred art forbids the human image lest this be confused with the representation of God. In this sense the human face and figure, even if God's vice-regent, is never to be used to image God. But Islamic art makes exuberant use of nature, particularly flowers and vines, and the Arabic letters of the Qur'an, as pointers to God's presence.

Nasr sees the Muslim world as having failed to cultivate an ecological spirituality and ethic in modern times, rooted in this Islamic vision of God as the ultimate environment of life, because of its poverty and colonization by the West. This colonization of Muslim lands, as in other regions, such as Asia and Africa, has resulted in a conflictual relation to Western power and technology, which is the main source of ecological devastation in the modern world. For Nasr, Christians too are part of a revelatory tradition in which God is present as the ultimate environment of human life. But they have replaced this faith with a view of Promethean (autonomous) man who has absolute and unlimited power over the earth, unrestrained by obligations to either God, fellow humanity or the rest of creation. It is this view of human autonomy that Nasr sees as an apostasy (renunciation) from God and as the root of the environmental crisis in the West that has infected the rest of the world through Western colonizing power.

Muslims have been torn between modernists, who have sought to emulate this power and technology of the West, without any critique of its effects in impoverishing the earth and the majority of human beings, and fundamentalists who have been resisting this Western influence, but have interpreted this resistance primarily in terms of restoring certain legal customs, such as female dress. The sapiential (wise) traditions of Islam have been ignored, and this has prevented the development of a deeper resistance to such devastation of the earth based on the vision of the relationship to God that is present in nature.

For Nasr the solution to the ecological crisis is, for Muslims and also other peoples, to recover those spiritual traditions that direct them to a proper relationship to God.

> Humanity cannot save the natural environment except by rediscovering the nexus between Spirit and nature and becoming once again aware of the sacred quality of the works of the Supreme Artisan ••• the solution to the environmental crisis can come about only when the modern spiritual malaise is cured and there is a rediscovery of the world of the Spirit, which, being compassionate, always gives of itself to those open and receptive to its vivifying rays. The bounty of nature and its generosity to the human race are proof of this reality, for despite all that we have done to destroy nature, she is still alive and reflects on her own level of being the love and compassion, the wisdom and the power, which belongs ultimately to the realm of the Spirit. In this crisis of unprecedented proportions, it is nature as God's primordial creation that will have the final say.

Nasr's words provide a profound challenge to Western Christians. What are the roots of an ecological spirituality and ethic in Christianity, and how have these been denied in the development of western technological society and its colonialist exportation? What is the connection between Christianity and this development of secularity, industrialism and colonialism? Are these developments simply a denial of the true Christian view of the nature–human relationship? It was common a generation ago to see secularity, industrialism and technology as the products of the Christian genius. But now that these are seen to have negative rather than positive impacts, many Christians have been questioning the association between Christianity and these western patterns of life.

Christianity is rooted in the Jewish tradition and shares with it the Hebrew Scripture. But the defining of this scripture as Old Testament also implies a reinterpretation of it as partially superceded. The parts of the Hebrew Bible that the Christian tradition has seen as superceded and no longer in force are particularly the legal codes which enshrine limitations on human use of nature; laws of kosher foods, sabbatical rest and avoidance of pollution.

After the first generation of Galilean Christianity, the early Christians were urban people without roots in rural life. Hence the Jewish legislation related to the renewal of the land made no sense to them. Christians became a people gathered from many ethnic groups and no longer related to a particular land and ethnic community. They defined the church as a new spiritual people of God who anticipated a heavenly kingdom beyond this earth, rather than as a renewed people and land within history of Jewish redemptive hopes.

Christianity also based itself in a realized messianism that understood Jesus of Nazareth as the incarnation of God. This violated the separation of God and humans central to Judaism. Both Judaism and Islam have strongly rejected this idea as idolatrous, as the divinizing of a human being. Christian redemptive hope in the early centuries spoke of God having become human so that humans could become God. But this did not lead, in classical or medieval Christianity, to a Promethean idea of the human as replacing God. This was because Christianity rooted itself in a concept of human fall and redemption that emphasized human sin and weakness and dependency on divine grace. Also, human redemptive hope did not focus on power over this present creation, but a transformation of creation into the Kingdom of God or the replacement of creation with a new spiritual creation beyond the present finite world.

These elements of denial of the body and the world in anticipation of a transcendent redemption outside of history have sometimes been seen as a major source of Christianity's negative relation to creation. Despising the body and the material world has been seen as leading Christians to neglect and abuse of nature. But there is not a clear relation between otherworldliness and the ecological crisis. The Christian view of nature was more complicated than is suggested by an anti-material stance.

Christianity in the second to third centuries contended with and rejected the most extreme forms of body-spirit dualism in the form of Gnosticism. The cosmological Christology that was developed by its leading anti-gnostic theologians, such as Irenaeus of Lyon, rooted redemption in the restoration and completion of creation, as body and spirit together.

Humans were made in the image of God and mandated to grow into the likeness of God by increasing union of the human with the divine will. But humans created a break between God's will and their own willfulness. God sent a series of revelations to return humans to the right path, culminating in the incarnation of Christ. Christ is the incarnation in human form of the divine Logos through which the world was created in the beginning. This is understood as renewing the ontological (the nature of) grounding of the whole creation, not just of humans.

In the incarnation of Christ, divine creative power permeates Nature in a deeper way so that the bodily becomes the sacramental bearer of the divine and the divine transforms the bodily into ever more spiritual and immortal form. This is seen as taking place in three stages. There is the era of the Church when Christians grow ever more unified with God through Christ in the sacraments. Next comes a millennial era when the whole of creation experiences peace and harmony in God. Finally there is the ultimate transformation of creation into an immortalized union with God.

In Irenaeus' words:

> For there is one Son who accomplished his Father's will and one human race also in whom the mysteries of God are wrought ••• the wisdom of God, by means of which his handiwork, confirmed and incorporated with his Son, is brought to perfection; that is, His offspring, the First-Begotten Word should descend to the creature ••• and that it should be contained in Him, and on the other hand that the creature should contain the Word, and ascend to Him, passing beyond the angels, and be made after the image and likeness of God.
> (Adv Haer.V.36.3)

Classical Christianity through the middle ages situated itself in a profound tension between a demonic and a sacramental view of creation. As cut off from and alienated from God, not only humanity, but the whole creation is distorted and becomes an instrument of evil. But as renewed in Christ, it is reunited with the divine Word, the creator, sustainer and redeemer of the universe. Seen through the eyes of Christ, the whole universe is sacramental; all things become signs that testify to the presence of God, its creator, and lead the seeker to contemplative union with God.

Christian monastic life is a good example of this tension between world denial and world renewal in Christianity. As a way of life that flees sexuality, the body and the world, it may seem to be the epitome of a Christian negation

of the goodness of creation. Yet in its main expressions, particularly in the Benedictine tradition, asceticism is not a rejection of the body and the earth, but rather a rejection of exploitation and excess, a return to simple living in harmony with other humans and creation. Even fasting and the vegetarian diet are seen as creating harmony of body and spirit, restoring the paradisiacal age before the fall into sin.

Monastic life is seen as representing the beginning of a restoration of the original harmony and justice. Communal property overcomes the exploitative division of God's creation into private property that sets up unjust divisions between poor and rich, destroying God's original intention that the earth be shared by all equally. The monk befriends animals who minister to him, overcoming the enmity between humans and animals that came about after the flood (Gen. 9:2–3). Monastic communities returned to a simple, subsistence form of life that pioneered sustainable agriculture at a time when the unsustainable system of military and slave-driven urban organization of late Roman life was toppling. Monastic communities were centers of literacy and education, as well as sources of service to society and to the poor.

Not surprisingly, the creation of new forms of Christian ecological community today that seek to withdraw from consumerism, create sustainable societies and witness against injustice in society often model themselves on new forms of monastic life. One of the Christian ecological movements in the United States seeking to create such ecological communities is *Sisters for Earth*, a network of Roman Catholic religious women who seek to reshape their lands, buildings and community life to make them centers of ecological living and learning.

The Calvinist Reformation and the Scientific Revolution in the 16th and 17th centuries represent key turning points in the Western concept of its relation to nature. In these two movements the medieval struggle between sacramental and demonic views of nature were recast. Calvinism dismembered the medieval sacramental view of nature. For Calvinism, nature was totally depraved. There was no residue in it of divine presence that could sustain natural knowledge or any relationship to God. Redemptive knowledge descends from beyond nature, in the form of the revealed word available only through scripture, as preached by the Reformers.

While Calvinism dismembered the sacramental view of nature, it reinforced its demonic universe. The fallen world, the physical universe, as human groups outside of the Calvinist Church, lay in the grip of the Devil. Even within the Calvinist Church, the threat of the Devil lurked. Women particularly were the gateway of the Devil. Among Protestants, Calvinists in Scotland and New England were the primary witch hunters.

The Scientific Revolution appeared to move in the opposite direction. It sought to exorcise the demonic from nature, reclaiming the universe as an icon of divine reason manifest in the laws of nature, knowable through empirical observation and mathematics. In the 17th and 18th centuries the more animist forms of natural science that sought to unify spirit and matter lost out to a strict dualism of transcendent intellect and dead matter, of Newtonian Physics and Cartesian Reason.

Nature was secularized. It was no longer seen as the theatre for a cosmic struggle between God and the Devil. Both demonic and angelic spirits were driven out of it. God was excluded from any active presence in nature to become the distant first cause and finally disappeared altogether as a scientific premise. Nature becomes dead matter in motion, moving obediently according to mathematical laws knowable to a new priesthood of scientists.

According to Roger Bacon (*Novum Organum* and *The Masculine Birth of Time*), due to Eve's disobedience humans lost their original dominion over nature. Through science, this dominion over nature will be restored to human hands. As the presupposition of divine ownership of nature disappears, humans, specifically the male elite of scientists and entrepreneurs, are understood as having unlimited, sovereign power over nature to do with it what they will. It is here that we find the birth of the Promethean man decried by Seyyed Hossein Nasr.

In Western society, the application of science to technological power and use of nature marched side by side with colonialism. From the 16th to the 20th centuries Western Europeans would appropriate the lands of the Americas, Asia, Africa and the Middle East and reduce their populations to slavery or low paid labor. The wealth accrued from this vast appropriation of land, its resources, and human labor would fuel ever new levels of technological development, transforming material resources into new forms of energy and mechanical work, control of disease, increasing speed of communication and travel.

With this expanding wealth and power, the western elite grew increasingly optimistic, imagining that this expanding technology would gradually conquer all problems of material scarcity and push back the limits of human mortality. Christian hope for millennial blessedness in the culminating era of history was translated into scientific technological terms as the ideology of endless progress.

However in a short three-quarters of a century this dream of infinite progress has turned into a nightmare. The medical conquest of disease, lessening infant mortality and doubling the life span of the affluent, insufficiently matched by birth limitation, especially among the poorest, has created a population explosion that is outrunning the food supply. The gap between poor and rich, between a wealthy, industrialized section of the world and the impoverished masses has grown ever wider in the last 25 years. Increasingly global society is being split between two worlds, those who enjoy the benefits of ever expanding

forms of technology, and those who have fallen out of the bottom of the modernized world into desperate poverty: reverting to pre-industrial means of subsistence or surviving on the garbage of the affluent world.

The western scientific and industrial revolutions have been built on injustice from the beginning. It has been based on a vast takeover of land, agricultural, forest and mineral wealth, appropriated through the exploitation of indigenous peoples. This wealth has flowed back to enrich the West, together with local elite, while impoverishing the land and the exploited people. This system of global affluence, with its high consumption of energy and its waste, cannot be expanded to include the poor without destroying the basis of life on the planet itself. We are literally destroying the air, water and soil on which human and planetary life depends.

Can this global system be changed to avert disaster, and do the world's religions have something to contribute to this conversion? I believe that religious traditions have both wisdom and motivational power to contribute. The three Abrahamic faiths, Judaism, Christianity and Islam, have important insights that can guide such a transformation. A key change in self-understanding is found in the belief that humans do not have absolute power of nature. Rather they have a delegated role for which they must be responsible to the ultimate source of life. Religious laws that mandate limited use of nature, and that understood humans, God and nature as standing in a covenantal relationship, calling for periodic restoration of justice and sustainable balances, can inspire us today.

Global movements, such as the Jubilee 2000 project to cancel the global debt of the poorest countries, and international covenants to limit toxic wastes, draw on this Biblical tradition. Efforts to create a global ethic accepted by all world religions, such as the one crafted by the meeting of the Parliament of the World's Religions in Chicago in 1994, seek to draw on religious traditions for ecological guidance. The development of a World Charter for Nature, that would parallel the International Declaration of Human Rights, is a similar effort to create a global ecological ethic based on all the world's moral traditions.

Religious traditions are critical to providing the vision, and the spiritual commitment, to make such a change. But these traditions are only beginning to overcome their ancient animosities toward each other and to translate their insights into practical guidelines to guide human development toward more just and sustainable ways of living.

Religion and Environment Among North American First Nations

Freda Rajotte
Canadian Coalition for Ecology, Dauphin, Canada

The First Nations peoples of North America consist of several hundred distinct ethnic groups, each of which had a unique language and culture, and which, at the time of European colonization, had adapted differently to the particular physical environment in which they lived. The last 500 years have seen vast changes to both the physical and cultural (economic, social and political) environment. The adaptation of each tribal or ethnic group of First Nations peoples to these changes has been in uenced by many factors, including: the degree of persecution, suppression, assimilation and forced migration, size of reservation lands, their isolation or degree of proximity to urban centers and markets, the presence of minerals, timber, arable soils and other resources, and above all to the degree that they have been able to retain or reconstitute their own religious belief systems and values as distinct from the North American mainstream.

INTRODUCTION

At the time when European settlement in North America began in the 16th century the land was already occupied by a great variety of different ethnic and cultural groups that have been referred to collectively as *Natives*, *Aboriginals*, *Indians*, or the preferred term, which will be used here *First Nations*. Each group developed its own culture, language, life style and traditions, and each is the subject of numerous anthropological, social and economic studies. At least 300 different languages were spoken. Despite this diversity, it is possible to make some generalizations concerning life style and relationship with the physical environment.

Settlement of the North American continent began somewhere between 40 000 and 30 000 years ago, and scholars generally agree that it consisted of numerous groups migrating from Northern China and Northeastern Asia over a long period of time. They came via the Aleutian Islands, which formed a land bridge across the Bering Sea during the last Ice Age, between approximately 30 000 and 14 000 years BP (before the present), when moisture was locked up in glaciers and vast continental ice caps, and sea levels were lower.

Through thousands of years of migration and cultural evolution, every part of North America became settled. (While this article considers only the Canada and US mainland, migration lled Mexico, Central and South America as well.) As the continental glaciers withdrew, people hunted and settled on the land progressively revealed by the retreating ice. And everywhere, the people adapted their life styles and culture to the vastly different environmental conditions. From the arid lands bordering Mexico to the rain forests of the Paci c Northwest coast, to the Arctic Circle, tribal groups developed methods of hunting, shing, cultivation, house construction and social organization that uniquely suited the resources and the land.

In each area the life style and economy became adapted to the local environment. Major factors included the abundance of animals and sh; the type and density of vegetation, the fertility of the soil and ease with which it could be cultivated; the length of the growing season, and the abundance of materials (wood, adobe, hides, etc.) for the construction of housing. Above all the climate was a major factor in uencing clothing styles, housing types, and the seasonality of activities such as hunting local wildlife and migratory herds, and cultivation of crops.

This lengthy period of settlement by First Nations peoples certainly had an impact on the North American environment. However, the extent of this impact varied considerably according to the environmental region and cultural life style of the people and was very minimal compared to the impact of human activities during the 20th century. For example, it seems certain that the systematic use of re kept the grassland plains of the continental interior relatively free from forest encroachment, and undoubtedly increased the extent of these lands. In the arid Southwestern US, there is evidence of some pueblo settlements having been abandoned before the arrival of Europeans. It appears that the removal of trees from the surrounding hills had increased the aridity of the land used for cultivation and speeded its deterioration.

The environmental impact of people was restricted by the simple fact that if the people did not adapt to the cycles of the seasons, or if they depleted the animal or plant resources, they would die. The knowledge and skills needed for hunting, shing, farming, gathering medicinal herbs, storing food, raising children, building and carving, constructing houses and making clothing, boats and weapons, were passed on from generation to generation. Winter was generally regarded as the season for story telling and passing on myths of origin, tribal histories and knowledge concerning social roles and expectations. Stories, mythologies, rites, dances, ceremonies and rituals all served to keep the cultures alive and vital. Thus, over thousands of years, the First Nations peoples developed unique ways of living in relative harmony both within their social groups and with the natural world around them.

Traditionally northern groups in the taiga forests, Arctic tundra and barren lands, have followed a seasonal migration pattern, shing and sealing in the Arctic waters, and following the caribou herds in their annual migration across the Arctic plains. While some still follow this same pattern, almost all carry with them modern, high-powered, hunting ri es and steel traps. Many travel to hunt or sh by snowmobile, and depend to varying extent on supplies own in from the South. The use of traditional dog sleds or of kayaks is increasingly becoming a pleasure and tourist activity. Military activities and oil exploitation in the Arctic pose a serious danger to the continued existence and health of the remaining caribou herds.

In the heavily forested Northwest coastal regions, marine resources were abundant. Hunting and berry picking supplemented shing. Here, many communities had winter villages with substantial community and family lodges, and also temporary summer quarters where families moved at the time of the salmon migration up river to harvest and dry sh. With forests of giant trees at hand, and an abundance of food easily available, there was time and energy to build huge timber lodges, and giant ocean-going canoes. Even the decorative arts such as wood carving had reached an amazingly advanced and stylistic form.

In North America s vast interior plains, the buffalo herds once provided the basic support for the life of the people, supplying them not only with food, but also with materials for clothing, shelter and weapons. The buffalo was so important that it also became central to their mythology and rituals.

In the forested regions of Eastern America, the basic activity of hunting was supplemented by harvesting natural products, such as wild rice, maple sugar and berries and by cultivating gardens of squash, corn and tobacco.

In the dry southwest of America, in the semi-desert and high plateau regions, corn has traditionally been the basic staple. It is generally grown together with beans, squash, potatoes and a mixture of many other indigenous crops such as peppers and tobacco. Here, people are particularly dependent upon the rainfall, and many of the religious rites and ceremonies are related to rain and the successful harvest of the corn crop.

During this long period in pre-contact America, there was not only an extraordinary diversity of tribal cultures and languages, but also an equally diverse range of mythologies and religious ceremonies and rituals. From the seasonal chants and ceremonial dances of the Pueblo peoples of the southwestern deserts, to the shamanistic practices of the nomadic Inuit of the Arctic, from the totemic peoples of the Pacific Northwest coast to the buffalo hunters of the plains, or the lodge societies of the eastern woodlands, it was hardly possible to speak in general terms of a single Native or First Nations religion.

However, as noted by Clarkson *et al.* (1992) The life of people became a reflection of the life of the earth and our ancestors became intimately connected and inseparable from these realities. Through many years of experience, trial and error, hunger and hardship, our ancestors learned that the depletion of plant and animal life in their immediate environment meant starvation and death .

IMPACT OF IMMIGRATION

When Columbus landed in the Americas just over 500 years ago it has been estimated that there were at least 100 million people, or approximately one-fifth of the human race living there. Almost immediately on contact this population began to decline. This was partly due to warfare and to the superior weapons of the settlers; but, far more seriously, during the first hundred years or more it was due to exposure to European diseases.

The ships that followed Columbus in ever increasing numbers, brought not only explorers, soldiers, gold seekers, and missionaries, but also off-loaded domestic animals and plants, and even unwanted pests such as rats and fleas. Perhaps the most destructive of all the new arrivals were the European viruses for which the Native American people had no immunity. Wave after wave of epidemics of influenza, diphtheria, smallpox, measles, tuberculosis, chicken pox and cholera swept through the Americas, until;

> less than a tenth of the original population remained. Perhaps 90 million had died ••• It was the greatest mortality in history. (Wright, 1993)

When the first European settlers began to arrive on the east coast, it was the First Nation peoples who introduced them to many new things essential for their survival. These included canoes and snowshoes, unfamiliar wildlife such as the moose, beaver and wild turkey, and domestic crops such as tobacco, pumpkins, beans and corn. However, soon the tide of land-hungry immigrants grew in number and surged westwards across the continent, surveying and dividing up the land into private farms and townships.

The very different belief systems, and opposing views on the relationship between people and the land, underlay much of the tragedy of mutual misunderstanding and conflict between First Nation and immigrant peoples.

During the past 500 years, not only were the First Nations populations decimated and dispossessed of almost all of their lands, but European immigrants brought with them their own politico-economic views (predominantly capitalism, private ownership and profit) and their own religious systems (predominantly various Christian denominations). Clearly each could have learned much from the other, but sadly a relationship of great potential turned into a tragedy of mutual incomprehension. European settlers had no concept of *hierophantic* Nature, i.e., of Nature being an embodiment of the spirit world. Native Americans did not think in terms of personal ownership of sections of land, nor of hunting and killing for sport.

It is a mark of particularly obtuse religious blindness, that governments, which established religious freedom clauses in their constitutions, suppressed Native religious practices, while giving free reign to Christian missions and residential schools. Not only were Native traditional belief systems eroded or obliterated, but also their religious ceremonies, such as the sun dance, potlatch, and sweat lodge were made illegal. Sacred objects were stolen to be sold as curios or art objects, many finding their way into museums of anthropology around the world. Even graves were plundered and ancestral bones exhumed and taken for study or display.

The new arrivals saw the land as virgin and empty: free for the taking. It only awaited civilization and development for its forests, soils and minerals to yield vast riches. In the way, however, stood mountain ranges, impenetrable forests, vast plains with an unbelievably harsh climate, and the last remnants of the indigenous population. All were seen as challenges to be overcome, as obstacles to be conquered, or as hindrances to be swept away.

Throughout the 19th century, armed confrontation frequently took place between First Nations peoples and settlers. Armed with superior weapons, and often supported by military forces, the settlers inflicted heavy casualties, and pushed the remnant indigenous peoples onto small areas of reservation land. Treaties were made between various First Nations and Britain (in the case of Canada) and the American government, and were as quickly ignored

and broken by the settlers. Systematically, encroachment or annexation reduced or eliminated these reservation lands.

On several occasions, cart loads of blankets infested with diseases, such as smallpox, were used to wipe out entire Tribal groups. Some groups, such as the Beothuk peoples of Newfoundland, were eliminated by genocide. Other groups were so depleted that the few remaining families moved away, died out, or intermarried and merged into the larger population. Sometimes entire peoples were illegally relocated to poorer and more remote locations. In 1830, US President Jackson signed into law a bill that required all Indians living in the east (predominately Cherokee) to leave their homes and be relocated west of the Mississippi River. During the long trek, called the Trail of Tears, guarded by federal soldiers, and attacked by bandits and thieves, many died of exhaustion, sickness and starvation.

Only in the more remote areas of the Northern taiga forests, in the Arctic regions, and among the Pueblo peoples of the arid Southwestern US, were the people never conquered nor forcibly removed, and so were able to maintain their traditional way of life.

IMPACT OF 500 YEARS OF EUROPEAN SETTLEMENT

First Nation peoples had always seen the land as sacred, as given by the Great Spirit or Creator. Those peoples belonged to the land, were part of the sacred circle of life, and were charged with protecting and preserving it. The European settlers and colonists perceived the land in a totally different way: for them land was a commodity, it was property, wealth, and security, to be measured out and owned. The land belonged to them; they did not belong to the land! The land became a resource to be bought and sold, but above all to be developed, controlled, mastered and made to produce.

While the First Nation peoples were trying desperately to retain their identity and their unity with the land, the inexorable westward migration of settlers across the Americas was focused upon something very different – upon the acquisition of free land and resources (timber, minerals and fertile soils). All were migrants, uprooted peoples, and most were poor. Many of them had been evicted from their homes (e.g., during the Scottish Highland Clearance), or had been displaced by war. The dreams and efforts of such immigrants and pioneers were focussed upon security, ownership and wealth. Their interests lay in claiming and fencing-in their personal property, in establishing homes and farms, towns and transportation routes. They brought with them familiar domestic animals and crops from Europe, and set about establishing a civilization similar to, but they hoped better than, that of Europe. They saw North America as a vast unoccupied space, as a place of limitless opportunity and freedom.

So, throughout the last 500 years, the ecology of North America has been vastly changed. The economy has been transformed from subsistence to commercial. The sparse population and small settlements have been replaced by a large and growing population centered in urban and industrial agglomerations.

The vast herds of buffalo of the continental interior have been eliminated, often wantonly, and the way of life of the Plains First Nations peoples wiped out. The prolific seas of both the east and west coasts, with their vast, seemingly inexhaustible shoals of fish, and beaches teaming with marine mammals, have been sadly depleted. Also, the great salmon runs of the rivers of both the Pacific Northwest and of the Atlantic Northeast coasts have been either destroyed entirely by damming or greatly depleted by over-fishing, pollution, or water diversion for urban, agricultural or industrial use.

And while settlers cleared vast areas of forestland for cultivation, most of the remaining forested areas have been clear cut. In some areas they have been cut two or three times, to provide both lumber and raw material for the pulp and paper industry. Many species of animals and plants, once plentiful, are either extinct, like the passenger pigeon, or endangered as their habitat is destroyed or as they are relentlessly hunted and trapped.

In a mad rush after gold, the land could be ripped apart, and slag heaps left to mar and poison the landscape for generations. However, the early gold rushes in California and the Yukon were as nothing compared to the open cast coal, copper and iron ore mines, and the oil and gas exploitation, that were to follow.

A TIME OF RENEWAL AND HOPE

In the 19th century, government policies in both Canada and the US favoured forced assimilation. In the US, the Dawes General Allotment Act of 1887 resulted in another 86 million acres (35 million ha) of reservation land being lost and at least 90 000 indigenous people being left homeless. A battered and demoralized remnant population seemed to have little will or ability to oppose two of the most powerful governments of modern industrial states. Even in the 1950s discussions were still underway to consider the termination of federal government responsibility for reservation lands in the US, and the extinguishment of treaty rights and status in Canada.

Amazingly, in the early 1960s, a series of Native conferences and growing protest movements gathered public attention and increasing general support to rectify and make amends for such a vast injustice. Several startling military confrontation – Wounded Knee (1973, in North Dakota, US), and Kanehsatake (1990, in Oka, Quebec, Canada) – were widely covered by media and seen on TV screens around the world, underlining the urgency of the

situation. These events and numerous others, such as the highly publicized reoccupation of Alcatraz Island (off the California coast, formerly used as a prison), acted as a catalyst to First Nations peoples.

Miraculously, since the 1960s, there has also been a remarkable renaissance of traditional religious beliefs and practices. This renaissance underlies and sustains a huge surge in cultural pride that is reflected in everything from art and clothing, to restoring tribal languages, economic development, and filing land claims. Scholars have begun to take a more open view of Native religious traditions. Disillusioned by the destructiveness of western culture, some people have begun to look to First Nations' elders for a spiritual understanding that is more respectful of nature and of community values. This religious revival has created a widespread interest and even a following among the general population, a surprisingly large and growing number of whom may attend powwows, are eager to study traditional Native spirituality, and participate in some of the ceremonies.

RESPONDING TO THE MODERN ENVIRONMENTAL SITUATION

The adaptation of First Nations peoples to environmental change can only be understood in the context of the history of the last 500 years of European contact. For First Nations peoples, it has been 500 years of occupation, epidemics, and disinheritance, of broken treaties, stolen land, racism and increasing impoverishment. All too often this resulted in a legacy of despair, poverty, high unemployment, and the alcoholism and violence that are generated by these conditions. Today, approximately half of all those claiming First Nation or part First Nation ancestry are living in urban areas, have intermarried, or have been assimilated into the general population.

Because of racism and discriminatory government policies, very few Native people not on the reservation lands are independent farmers.

On the reservations, a different and detailed answer would have to be given in each case, according to factors such as: the size of the land base, size of the population, degree of forced relocation, traditional skills, proximity to urban areas and markets, resource base and climate zone, degree of political autonomy, and educational level of the population.

In 1975 the crucial Self-determination Act was passed in the US and 150 groups immediately filed for official tribal status. Many more applications are currently being filed. Each recognized tribe enjoys a direct government-to-government relationship with the US, and can establish its own government, tribal court, police and educational system. Freed from federal and state regulations, the tribal governments can and do turn reserve lands into anything from nuclear waste dumps, to casinos and resort developments. In Connecticut, the Mashantucket-Pequot now own one of the largest casinos in the world employing over 9000 people. By the late 1990s, more than 160 US tribes and several reserves in Canada (e.g., Rama, Ontario) were operating casinos.

In Canada almost every reserve has established its tribal land claim office, and is preparing for, or has already filed, a land claim before the relevant government (provincial, territorial or federal). Some of the first substantial land claims to have been heard have been upheld by the courts.

RESTORING ANCIENT TEACHINGS IN A MODERN CONTEXT

After nearly 500 years of cultural suppression, many First Nations people care very little about spirituality or nature, or about traditional ceremonies. In many communities the majority may be adherents of some Christian denomination, or of the Native American Church (the most widespread religion among US Native peoples), which combines some fundamentalist Christian beliefs with Native teachings. Its most important sacrament involves the eating of the buttons of the peyote, a hallucinogenic cactus (still classed as an illegal act in the US).

Among the First Nations of Southwestern America, the Ute, Apache, Navajo and other Pueblo nations who were never conquered or displaced, many of the traditional teachings and rituals, healing chants and sand paintings, as well as the seasonal dances with katchina masks, remain virtually unchanged and intact. Similarly the Iroquois ceremonies conducted in longhouses in northeastern US, and closely tied to the agricultural seasons, appear to have changed very little.

Where fundamental rituals and ceremonies were banned and made illegal, many tribal societies are now carefully researching and reestablishing them. For example, the Potlatch feast, with its masked dancers and lavish give-away ceremonies of the Pacific Northwest coast, associated with the Kwakiutl, Nootka, Haida, Tsimshian, Tlingit and Salish societies, was declared illegal from 1884 until 1951. It has now been reinstated, with an associated revival of master carvers preparing spectacular dance masks, totem carvings, and large sea-going canoes. Today many young people learn to dance and act the ancient stories and legends of their ancestral heritage. This is paralleled on the central plains, by the reestablishment of the annual sun-dance ceremony on many reserves, and the almost ubiquitous sweat lodges, which are constructed at almost all powwows, ceremonies and local celebrations. Its use has become popular with non-Native peoples as has smudging, which involves carrying a braid of smoldering sweetgrass around the circle

and offering it to each person so that they may cleanse themselves in its smoke.

A sweat lodge (or *impi*) is a small circular dome of willow branches, half sunk into the earth, and always directionally oriented, into which the shaman or elder brings heated rocks. In the dark interior of the lodge, water is poured onto the rocks producing steam. Participants experience a primordial microcosm of creation, similar to reentering the womb, constituted of earth, air, fire and water. It is a ceremony of cleansing and rebirth. The Iroquois Mide peoples and the Kivas of the Pueblo peoples use a similar symbolism.

At the other extreme are numerous communities where ancient beliefs and traditions are irrecoverably lost, where remnant populations were displaced from their lands and forcibly moved, some many times over, to make way for European settlers. While much has been lost, an astonishing amount remains or has been reconstituted. Today native people travel widely and many join in the powwow circuit, traveling from one community powwow to the next. Research and information are communicated rapidly by email, fax and phone, so that similar customs and teachings spread easily over a wide area. Native Spirituality is a recognized university course in many Native Studies departments, and many elders give seminars or otherwise make their teachings available to the general public. Today, it even seems possible, while acknowledging the diversity of ceremonies and rituals, to make certain generalizations about First Nation's faith and belief systems.

FAITH AND BELIEF SYSTEMS AMONG FIRST NATIONS

All First Nations traditions recognize the interconnectedness of the human, natural, and spirit worlds. The inclusiveness of the circle or Sacred Hoop has become the almost universal symbol for Native spirituality. It encompasses all the directions (east, north, south and west), all four seasons (Spring, Summer, Autumn and Winter), and all stages of life (infant, youth, adult and elder). It can be used as a basis of prayer and thanksgiving to offer thanks to all four directions, all kinds of weather, and all aspects of life – for all times of day: dawn, daylight, sunset and night. It can be used as a guide to the correct building and sighting of a pueblo, lodge or teepee. It is the symbol for completeness and inclusiveness of the whole community, and the whole of the interrelated creation:

> You have noticed that everything an Indian does is in a circle, and that is because the power of the world always works in circles, and everything tries to be round.
>
> In the old days when we were a strong and happy people, all our power came to us from the sacred hoop of the nation, and as long as the hoop was unbroken, the people flourished. The flowering tree was at the center of the hoop, and the circle of the four quarters nourished it. The east gave peace and light, the south gave warmth, the west gave rain, and the north with its cold and mighty wind gave us strength and endurance. This knowledge came to us from the outer world with our religion. Everything the power of the world does is done in a circle. The sky is round, and I have heard that the earth is round like a ball, and so are all the stars ••• Even the seasons form a great circle in their changing, and always come back again to where they were. ••• Our teepees were round like the nests of birds, and these were always set in a circle, the nation's hoop, and nest of many nests, where the Great Spirit meant for us to hatch our children.
>
> (Black Elk Speaks, 1988)

In contrast, European settlers superimposed straight lines and grid patterns upon the land. Railways and roads cross the plains in straight lines for hundreds of km; property is divided up into rectangular parcels.

There is a common awareness that life is spiritual: everything that exists has within it an element of sacredness. Nature, in its entirety, is *hierophantic* that is, a source of spiritual revelation. Everything – the land, water and sky, sun, moon and stars, plants, animals, birds, fish and people – all manifest some aspect of the spiritual reality that infuses the whole of creation. This basic view of the world means that Mother Earth (the major source of all life) must be treated with respect, not viewed as a commodity to be owned, or bought and sold. The physical environment should only be used with care and reverence. A successful hunt or a good harvest was accepted with thanksgiving and the food was shared among the community so that no one was in want. Neither does Nature exist solely for human use. All life has access rights to the use of land, water and air.

Ceremonies among First Nation North Americans generally center around the drum. The drum may be referred to as the heartbeat of Mother Earth, and forms a connection to the spirit world. Around the drum with its circle of drummers and singers, the dancers move in a large circle, feet close to the earth, and moving to the rhythmic beat and chants.

First Nations peoples respect animals as sacred. Traditionally, prayer and ritual accompanied hunting, which was seen as a sacred activity, only undertaken when food was needed. Care was taken to give thanksgiving following a successful hunt, and to respect the animal that had been killed to provide food and materials for clothing, etc. Great care was taken not to over-hunt or endanger a species' existence.

However, from the earliest days of contact with Europeans, Natives were encouraged to hunt and trap for furs and pelts for trading. Today, many, especially in the northern taiga forests, still earn a significant income from running trap lines or hunting, but snowmobiles are generally used to reach trap lines, and high-powered rifles for hunting.

This has caused controversy over the relationship between traditional practices and hunting rights claims.

For each clan and people, certain creatures have a greater spiritual significance. Individuals may undertake a vision quest (several days of solitary fasting and prayer in a wilderness area) during which time they may receive a revelation from the spirit world through a specific creature, which will then become their guardian spirit. People enter a special relationship with their guardian animal, never hunting or harming it in any way, but seeking its presence, assistance and wisdom. Through their sacred animal (eagle, buffalo, bear, snake, raven or other creature), the spirit-being manifests itself as a personal or as a clan protector. Some claim that they receive warnings or guidance or even that their lives have been saved during a crisis such as sickness, fire or a car crash, by their guardian animal.

The totem carvings of the Northwest Pacific coast are like heraldic crests. Each pole recounts a specific clan history and mythology, recounting the stories of the relationship of clan elders with guardian and sacred animal spirits (actual animals like the raven or whale) or mythological ones (like the thunderbird). That creatures embody the invisible spiritual realm is the profound meaning underlying sacred mask dances, e.g., the seasonal cycles of katchina dances of the Southwestern Pueblo peoples. In these dances, the spiritual reality becomes embodied in and takes possession of the physical form of the mask and the dancer so that the dancer becomes temporarily the actual manifestation of the ancestral or animal spirit. (This is similar to claiming the actual presence of Christ in the elements of the Christian mass.)

Shamans or medicine men or women are central to the traditional belief systems and rituals of First Nations peoples throughout North America. They are highly respected as intermediaries between the spiritual and material worlds, and can also effect healing. Through solitude, communing with nature, fasting, prayer, purification and self-discipline, shamans undertake journeys into the spiritual realm, where they seek help and assistance, wisdom and healing power. Revered shamans and elders are recognized and honored by becoming pipe bearers. Smoking the sacred pipe is undertaken to bring the smoker into close contact with the spirit world.

While some Shamans may be trained in western medicine or nursing, all have a profound knowledge of the medicinal properties of local herbs. They are concerned not only with physical healing, for which many patients may go first to a local clinic or hospital, but also with holistic healing of body, mind and spirit. They can be effective both with individuals and with communities that are experiencing high levels of unemployment, poverty, despair, addiction, violence and soaring youth suicide rates.

Native existence itself is deeply and inseparably rooted in the land – in Mother Earth. The land belongs to all creatures that live upon it. A people's traditional economy, culture and self-image are based upon the continuous habitation of place . Myths of origin, cultural histories, and self-perception, as well as rituals and sacred sites are located in and around a tribe's traditional lands. It is alone, in nature, that one goes on a vision quest to seek wisdom. Mother Earth nurtures us, feeds us, inspires us, and it is back into the land that our bodies are returned at death. The earth is sacred. People and place together form a sacred cultural unity. While all of nature is the theatre for spiritual revelation, these specific sacred sites are incorporated into tribal mythologies and rituals. Each site is affiliated with a specific local mythology and tribal history. Thus, the relocation of a tribal group or destruction of the site means that essential links to the spirit world are lost. To understand this is to understand why the conquest and removal of people from their traditional lands was cultural genocide.

Throughout North America specific landforms, such as springs, mountains or high bluffs are regarded as especially sacred. Here spiritual elders and shamans commune with the mystery of the spirit realm and receive visions, revelations and healing power. Sacred sites may be enhanced with petroglyphs, medicine wheels (marked out in rocks), or earth mounds (such as the Great Serpent Mound of Ohio). For pueblo peoples, kivas – subterranean rock-built chambers – mark the site where the original peoples emerged from the underworld. While most sites have been defaced or even completely destroyed over the last 500 years, attempts are now being made by many First Nation peoples to protect some of the remaining sites under constitutional freedom of religious practice clauses.

George Tinker, a First Nation author from Colorado explains that:

> Native American spirituality and values, social and political structures, and even ethics are rooted not in some temporal notion of history but in spatiality. This is perhaps the most dramatic (and largely unnoticed) cultural difference between Native American thought and western intellectual tradition. The question is not whether time or space is missing in one culture of the other, but which is dominant. Of course, Native Americans have a temporal awareness, but it is subordinate to our sense of place. Likewise the western tradition has a spatial awareness, but it lacks the priority of the temporal. Hence, progress, history, development, evolution and process become key notions that invade all academic discourse in the West.
>
> (Tinker, 1992)

The inner, spiritual forces that exist within all creatures, continue their never ending journey after the death of the outer physical form, and they may continue for a while to have a relationship with living beings, and influence events. Many ceremonies fulfill the function of mediation between the spirit world, the human world and the world of nature, for a continued and reciprocal relationship is perceived between the living and the dead. These ceremonies may show respect, offer thanksgiving for good fortune or

seek blessing upon future endeavors, e.g., successful hunts, abundant rainfall or healing.

Care must be taken that we do not harm nature. Many of the decisions made today by proprietors, corporations and governments take a very short-term view, and seek immediate profits. This shortsighted approach means that as governments change, and corporations merge or move, there is no accountability when the negative effects of industrialization policies become apparent many years or even decades later. In comparison, traditionally, when Native bands consider development options, they consider what the likely impact will be, not only for the immediate future, but also upon their children and children's children to the seventh generation.

TODAY AND TOMORROW

Throughout the 1990s and into the 21st century a resurgence of epic proportions has swept through the First Nation societies of North America, as they seek to free themselves from control and domination by colonial powers.

The recent resurgence of Native spirituality, while causing some social con ict, is generally leading to increased cultural pride. Many reservations now organize annual celebrations of traditional dancing and hold powwows, Indian days, Treaty days, or enact ceremonies, to which the general public is invited. Tourism is an increasingly important sector. There is also a recovery and development of traditional arts, from weaving carpets, making pottery or designing jewelry among the southern Pueblo peoples, to the carving of dance masks, boats, and traditional totem and house poles along the Northwest coast. In the far north, the Inuit produce stone carvings and prints that are in high demand in national and international art galleries. In the eastern forests and on the central plains, there has been a resurgence in the making of elaborate dance costumes, beaded foot wear, powwow costumes, canoes, snow shoes, and in the construction of traditional lodges.

First Nations peoples have held with amazing tenacity to their own understanding of people-land relationships which is radically different than that of the dominant majority. They continue to confront governmental, industrial and church agencies with their alternative world-view. Most elders today would see themselves as guardians of Mother Earth.

This has led them into increasingly frequent con ict with corporations and governments that plan to develop local resources by destructive means. Thus, there have been many demonstrations, marches, petitions, and road blockades trying to stop clear cut logging, open cast mining, dam construction, and military weapons testing on reservation lands, or on lands whose status is currently being claimed or disputed in the courts. The following examples may give some idea of the scale of the problem.

Although some 112 000 square km of the New Sogobia reservation was designated as the property of the Western Shoshone nation in 1863, and this was later con rmed in 1869, the US military has conducted some 670 weapon test explosions there since 1963, usurping 90% of their land.

> By 1980, 42 operating uranium mines, 10 uranium mills, ve coal power plants and four coal strip mines were in the vicinity of the Navajo reservation. Approximately 15 new uranium-mining operations were under construction on the reserve itself. Although 85% of Navajo households had no electricity, each year the Navajo nation exported enough energy resources to fuel the needs of the state of New Mexico for 32 years.
>
> (La Duke, 1992)

Despite continuing protest of the Innu People of Labrador and Northeast Quebec, their traditional life style has been rendered nearly impossible. In the 1950s, many were forcibly resettled into villages, when the Churchill River dam ooded ancient burial grounds and important areas of their hunting territory. In the early 1980s, the military base of Goose Bay was established, and used as a North Atlantic Treaty Organization (NATO) training base for low-level ight, which disturbs the caribou herds and makes sustained hunting impossible. Now mining companies have led over 13 000 claims in the area around Voisey Bay, Labrador.

Coal strip mining is a particular problem to the Cheyenne and Navajo-Hopi peoples. The Cheyenne reservation is virtually surrounded by coal strip mines, railroads, electric generating plants and transmission lines. Adjoining the reserve lies the largest federal coal sale in the history of the US the Powder River Coal lease, which follows the major water source the Tongue River.

Several coal- red power plants lie on or adjacent to the Navajo-Hopi lands, and the vast Black Mesa mine supplying coal to the Four Corners Power plant was the only man-made object seen by the Gemini Two astronauts from outer space. It caused not only pollution and falling water tables but also the relocation of some 10 000 people.

Across Canada, from the Queen Charlotte Islands of British Columbia, to Temagami, Ontario, to the Maritimes, First Nation peoples have been among the rst to organize protests against the huge timber leases sold to corporations for clear-cut logging. They have often been joined by the public in mass demonstrations, but have had only very limited success in changing government policies. For native people, the destruction of the forests together with their wildlife, and the deterioration of streams and rivers, and consequently of shing, has generally been disastrous. Although clear-cutting may generate a few short-term unskilled jobs for local First Nations people, trap lines are lost, hunting and traditional ways of life become more dif cult, and in the long-term it leads to increasing impoverishment of the community as a whole.

Similarly, almost all the major rivers in Canada have been dammed for hydroelectric developments. Some of these, like the Churchill Dam (Labrador), or the W A C Bennett Dam (British Columbia), or the vast James Bay Project of Northern Quebec, are among the largest engineering works of the 20th Century. Not only have the huge reservoirs behind the dams destroyed the most productive areas of lowland for vegetation, wildlife, and migratory birds, but sometimes the flow of rivers has been diverted or even reversed, resulting in the disruption of water tables, and resettlement of communities. Generally, if compensation is paid, it is only in cash, not in equivalent land and resources. This leaves the problem of increasing unemployment, cultural destruction, and despair in its wake.

In conclusion, one can only say that the response of First Nations peoples to 500 years of change in both the physical and social environment is in a state of very rapid transition. At one extreme are the isolated reservations where traditional reliance upon hunting and fishing (albeit using rifles, outboard motors, and snowmobiles) is still possible, although it may be seriously threatened by both the impact of pollution, and by the increasing corporate demand for resource exploitation. At the other extreme are examples like the Cherokee nation who have developed a large manufacturing center (including component parts for IBM, General Dynamics, and the US Army, among others), as well as retail and hotel sectors. The political and administrative center of Tahlequah handles an annual budget in excess of $75 million.

In two areas in particular, traditional ways of life have continued relatively undisturbed. One of these is on the vast semi-desert reservations of the Pueblo peoples of the Southwestern US. The other area is in the Canadian North and Alaska. The territory of Nunavut, established in 1999, covers approximately one-fifth of the land area of Canada. With a population of approximately 27 700 people, who are 90% aboriginal, it has the same autonomy as other territories and provinces. Even in both of these regions, modern transportation, education, medical services, expanding commercial sectors, resource exploitation and western forms of government and policing, create a large, and ever-increasing impact.

Unfortunately, in many of the smaller and more isolated reservations, where the land area is too small to support traditional hunting, and too poor to farm, as much as 90% of the population may still depend upon some form of government payments.

A few Native bands whose reservation land lies in large and growing urban centers have been able to develop their property and lease or rent it at considerable profit.

On many other reservations new commercial developments are appearing continuously: from casinos, shopping malls and tourist hotels to a resurgence of handcrafts, from toxic waste storage facilities to fashion designing. On independent band reservation land, mining and oil and gas exploitation is now generally under the management of Native corporations. On larger reservations, sustainable logging operations, modern farming and industrial developments are being established.

For the future, it seems safe to say that the only thing that is certain is continuing change. It would seem that the general movement towards increased autonomy will almost certainly continue in both the US and Canada. Eventually, the vast number of land claims will wend their way through the court systems, and be settled. However, the very size, number and complexity of claims (e.g., almost the entire land area of the province of British Columbia is currently being claimed by various Native bands) means that the final determination of land will inevitably disappoint many.

Will future developments on reservation lands be more environmentally sustainable than in North America as a whole? For the immediate future, the most urgent consideration for many band councils and governments is to improve the employment opportunities and raise the standard of living for people who have traditionally been impoverished and demoralized. Yet access to land is central to long-term indigenous health and cultural identity. Land and people are inseparably bound. The Native community can only be healthy in body, mind and spirit when the land is also healthy. The land is the promise of a healthy future for generations yet to come, it is where the bones of the ancestors lie, it links the past and the future, and it is sacred. Thus, while some indigenous people are among the poorest of the poor they are also holders of the key to the future survival of humanity.

Roosevelt, Theodore

(1858- 1919)

Theodore Roosevelt, US president (1901–1909), led one of the most dynamic lives of any US president. He was born into a wealthy and privileged New York family. Roosevelt's childhood was one of constant illness, but he overcame his infirmities through a self-imposed regimen of strenuous exercise. Strong will became a hallmark of his personality. He attended Harvard and studied law at Columbia.

In 1884, his wife Alice and his mother died on the same day – Alice from complications of childbirth, and his mother from a long illness. Roosevelt went to his ranch in the Dakota Territory where he slowly overcame his loss by living a tough physical life far from the world he knew in New York. In 1886, he married again, to Edith Carow.

During the Spanish–American War, Roosevelt was Lieutenant Colonel in the Rough Rider Regiment, and he led a famous charge at the battle of San Juan. This war hero status added to his celebrity image, and shortly after he was elected New York State Governor (1898).

Later, he served as vice president to William McKinley. McKinley was assassinated in 1901, and at the age of 43, Roosevelt became the youngest president in US history. He brought a new vigor to the presidency, a change from the staid and conservative McKinley. Roosevelt held the ideal that the government should be an arbiter and promoter of social and economic equity. Roosevelt embraced anti-trust legislation that soon dissolved monopolies in the railways and oil industry. The extensive use of executive power was a defining characteristic of his administration. He wrote I did not usurp power, but I did greatly broaden the use of executive power . Roosevelt believed that as steward of the people he must act forcefully to enhance the public good.

Roosevelt pushed the US toward a more discernable global role. Speak softly and carry a big stick was an adage he popularized. He backed construction of the Panama Canal, and won the Nobel Peace Prize for mediating an end to the Russo–Japanese War. However, he also had an important and lasting impact on conservation thought.

The time Roosevelt spent in the Dakotas had an impact on his tenure as president. He developed a love of the wilderness early in his life, and later saw the closing of the frontier and the settlement of the western landscape as the symbolic loss of what defined America. His friendships with John Muir and Gifford Pinchot provided kindred spirits for his romantic view of the American landscape, and they in turn greatly influenced his conservation program. Roosevelt's executive power gave him an opportunity to add vast areas of the west to the national forests, and to preserve places of special beauty such as the Grand Canyon. Despite this, he was a man of environmental contradictions – while being a keen observer of nature, he was also an avid hunter. Roosevelt's conservation was based on a utilitarian ideal – it was not about the absolute preservation of nature, but instead it was about the wise use of public lands and resources. His administration saw the creation of the first large resource bureaucracies. By the close of his presidency, Roosevelt had insured that the public would be the dominant landowner in the American West, and that the conservation ideal would long serve to guide the culture of American resource management.

Scenarios

Jerome C Glenn

American Council for the United Nations University, Washington, DC, USA

A scenario is a story that connects a description of a speci c future to present realities in a series of causal links that illustrate decisions and consequences. A speci c year should be stated, such as 2025, and subject focus like a country, an industry, peace and con ict, etc. A scenario is not a single prediction or forecast, but a way of organizing many statements about the future.

Herman Kahn was the father of scenario construction. He de ned scenarios as narrative descriptions of the future that focus attention on causal processes and decision points (Kahn, 1967).

The purpose of scenarios is to systematically explore, create, and test both possible and desirable future conditions. Scenarios can help generate long-term policies, strategies, and plans, which help bring desired and likely future circumstances in closer alignment. They can also expose ignorance; show that we do not know how to get to a speci c future or that it is impossible.

Exploratory or descriptive scenarios describe events and trends as they could evolve, based on alternative assumptions on how these events and trends may in uence the future. Normative scenarios describe how a desirable future can emerge from the present.

Although it is not possible to know the future, it is possible to in uence elements of it. The forces of nature, social and political dynamics, scienti c discovery, and technological innovation largely determine the future. However, human choice increasingly shapes the future. This in uence makes the effort to consider the balance between what we want and what is possible worthwhile.

Scenarios should be judged by their ability to help decision makers make policy now, rather than whether they turn out to be right or wrong. Good scenarios are those are: (1) plausible (a rational route from here to there that make causal processes and decisions explicit); (2) internally consistent (alternative scenarios should address similar issues so that they can be compared); (3) suf ciently interesting and exciting to make the future real enough to affect decision making.

A scenario could be constructed to show how continuing war, Acquired Immune De ciency Syndrome, and environmental destruction could lead to increased African migration to Europe, which triggers racial con icts. The purpose of this scenario would be to alert decision makers about strategic interventions to make the scenario wrong. Conversely, The Millennium Project (Glenn and Gordon, 2000) constructed a global normative scenario to the year 2050 to illustrate how policy could dramatically improve the human condition. Here the purpose was to organize hundreds of previously collected positive developments and strategies into one whole picture that showed how policies, technologies, and changing human behaviors could have synergistic effect, and might become self-ful lling to some degree.

Herman Kahn introduced the term and concept of scenarios into planning in connection with military and strategic studies conducted by the Rand Corporation in the 1950s. He further popularized the concept in the 1960s as director of the Hudson Institute, a private nonpro t research center devoted to issues related to US public policy, international development, and defense. In 1967, Kahn along with Anthony Weiner examined the future possibilities of world order, describing potential power alignments and international challenges to American security in a book entitled Toward The Year 2000 *(Kahn and Weiner, 1967). One of their worlds depicted an arms control agreement between the US and the former Soviet Union; another assumed the former Soviet Union would lose control of the Communist movement; a third projected construction of new*

alliances among countries. In the book, Kahn and Weiner also described the technology hardware of the future, which included centralized computer banks with extensive information on individuals as well as parents able to select the gender and personal characteristics of their children through genetic engineering. This work was done under the Commission on the Year 2000 sponsored by the American Academy of Arts and Sciences.

Since the future can never be accurately or completely known, most planners and futurists today reject the idea that planning should be conducted against a single most likely image of the future. Rather, sets of scenarios should be used in planning; if the sets encompass a broad span of futures and plans are generated to cope with their eventualities, then the plans will be robust and the future can be met with some degree of con dence.

The Millennium Project has produced the largest annotated scenario bibliography with over 400 scenario sets, available at http://www.acunu.org/millennium/information. html, which are organized in the Futures Matrix in the following domains: demographics and human resources; environmental change and biodiversity; technological capacity; governance and con ict; international economics and wealth; integration or whole futures.

DESCRIPTIONS OF SCENARIOS

The term *scenario* comes originally from the dramatic arts. In the theater, a scenario refers to an outline of the plot; in movies, a scenario is a summary or set of directions for the sequence of action. Peter Schwartz of Global Business Network, a think tank in Emeryville, CA, often compares the initial process of creating a scenario with writing a movie script (Schwartz, 1992). Often in creating a scenario, a team of people considers such questions as: what are the driving forces? What is uncertain? What is inevitable? Similarly, scriptwriters formulate an idea and develop characters. Schwartz describes characters as the building blocks of scenarios.

In general, the term *scenario* has been used in two different ways: first, to describe a snapshot in time, or the conditions of important variables at some particular time in the future; second, to describe a future history, i.e., the evolution from present conditions to one of several futures. The latter approach is generally preferred because it can lay out the causal chain of decisions and circumstances that lead from the present. The most useful scenarios are those that display the conditions of important variables over time. In this approach, the quantitative underpinning enriches the narrative evolution of conditions or of the variables; narratives describe the important events and developments that shape the variables.

When scenarios are used in futures research and policy analysis, the nature of evolutionary paths is often important since policies can deflect those paths. In policy studies, families of scenarios are often used to illustrate the consequences of different initial assumptions, different evolutionary conditions, or both. For example, a study of transportation policy might involve constructing several scenarios that differ in their assumptions about birth rates, population, migration, and economic conditions, as well as the costs and availability of various forms of energy. When a set of scenarios is prepared, each scenario usually treats the same or similar parameters, but the evolution and actual value of the parameters described in each scenario are different.

The goal of generating scenarios is to understand the mix of strategic decisions that are of maximum benefit in the face of various uncertainties and challenges posed by the external environment. Scenario building, in conjunction with a careful analysis of the driving forces, fosters systematic study of potential future possibilities – both good and bad. This forecasting approach enables decision makers and planners to grasp the long-term requirements for sustained advantage, growth, and avoidance of problems.

HOW TO CONSTRUCT ALTERNATIVE SCENARIOS

Numerous methods have been developed to create scenarios, ranging from simplistic to complex, qualitative to quantitative. Some are created by one author acting alone, some by teams; and others through global participatory processes as in the Millennium Project (Glenn and Gordon, 2000). Many methods have similarities, although they may have unique features and use different terminology. Most approaches recognize the need to understand the system under study and identify the trends, issues, and events that are critical to this system. While each is not feasible to explain in detail, a brief description of several and a lengthier description of one are worthwhile.

Coates & Jarratt of Washington, DC, US, uses the following process to develop scenarios for a variety of clients, including countries and businesses. Coates & Jarratt begin by defining the universe of the area of interest. Key variables shaping the future are identified using a wide range of sources. Usually some 6–30 variables affecting the future situation are nominated. This list is then winnowed down by eliminating redundancies, a process that usually results in 6–20 variables. In the next step, the scenarios to be created are defined. One scenario usually presents a continuation of the present forces at play. Other scenarios may include an optimistic or positive scenario, which may be based on one or two of the particularly prominent variables. These scenarios may involve such occurrences as a technological breakthrough or change in government policy. Other scenarios can be framed around important futures, such as business booms, collapses, or other important occurrences. In

general, 3–6 scenarios are usually sufficient. The variables are then reviewed to determine what is a plausible qualitative and quantitative range of the value for that scenario. The scenarios can then be assigned to individuals for creation. Once completed, the scenarios should be reviewed for comprehensiveness and completeness, and then edited to ensure consistency in approach, layout, style, and format.

Coates & Jarratt emphasize that scenarios can be used to achieve different goals. Whereas some are designed to present a completed future, others may be used as points of departure for future discussions, such as policy implications. On some occasions, transition scenarios may be appropriate to development that describes the process of getting to certain end states. These transition scenarios can be either a separate set of scenarios or part of the primary scenarios themselves.

Peter Schwartz, a former member of the Royal Dutch/Shell scenario team, describes several steps in the scenario development process in his work *The Art of the Long View*. These steps include: identify the focal issue or decision; identify the key forces and trends in the environment; rank the driving forces and trends by importance and uncertainty; select the scenario logics; fill out the scenarios; assess the implications; and select the leading indicators and signposts for monitoring purposes (Schwartz, 1991; 226–234).

Thomas Mandel and Ian Wilson of SRI International wrote an excellent description of scenarios in a report entitled *How Companies Use Scenarios: Practices and Prescriptions* (Mandel and Wilson, 1993). In this SRI report, the authors explain the scenario development process. In the first two steps, management decides what it needs to know in order to make business decisions, and a scenario team describes the events, trends, and uncertainties that could impact the decision-making process. The team then analyzes forces that will shape the future business environment, both from within its own industry (competition) and outside of it (social, political, economic, etc.). The team then develops scenario theories or logics, which are differing views of the way the world might work in the future. Each theory takes into account critical drivers and uncertainties. Using the theories already developed as a guide, the scenarios are then described in sufficient detail to identify implications of decisions and to help develop and assess strategy options.

Michel Godet, from the Laboratory for Investigation in Prospective Studies in Paris (Godet, 1993), begins the scenario development process by constructing a base image of the present state of a system. This image is broad in scope, detailed, and comprehensive, dynamic, and descriptive of forces for change. The base image is constructed by delineating the system being studied, including a complete listing of the variables that should be taken into consideration as well as subdivisions of these variables (i.e., internal and external, as descriptive of the general explanatory environment). This step is followed by a search for the principal determinants of the system and their parameters, often using structural analysis. The scenario process involves examining the current situation and identifying the mechanisms and the leading actors (influencers of the system through variables) that have controlled or altered the system in the past. This process continues with development of actors' strategies. Construction of the database is followed by construction of the scenarios.

Godet combines various futures research techniques in scenario development. For example, he finds that morphological analysis can be used in scenario construction since scenarios are, in essence, a configuration of identified components. Godet cites the large number of possible combinations as a drawback in this application of morphological analysis, but offers a solution in the form of computer software that helps limit the field.

Ute Von Reibnitz of Strategische Unternehmensberatung makes the case that the ability to create different futures situations allows planners to deal with scenarios that fall between two extremes. In his book *Scenario Techniques* (Von Reibnitz, 1988), Von Reibnitz describes the process of constructing scenarios. Step one entails an analysis of an organization's structure, strengths and weaknesses, and goals and strategies. Step two involves an examination of areas and factors of external influences with attention to their interrelationship and dynamics. Step three is an analysis of the development of the future of influencing factors. Step four clusters different alternatives to form logical and plausible structures for scenarios. Step five incorporates these structures into scenarios that describe system dynamics and changes. The process concludes in Step six with an analysis of opportunities and risks.

In *Business Futures*, the Institute for Futures Research (1992) has presented yet another approach that begins with the identification of key issues. This step is subdivided into definition of mission, objectives and aims, and description of strategies and key decision-making parameters, followed by identification of key environmental forces, composed of environmental scanning, spotlighting of crucial issues, and listing predetermined events and forces for change. In the next step, the scenario logic is defined, the actors identified, and their likely behavior examined. Multiple scenarios are then created, and the implications of each are tested. The concluding step involves presentation of these scenarios to planning forums in order to evaluate their implications for action programs.

The Millennium Project of the American Council for the United Nations University (Glenn and Gordon, 2000) uses large-scale participatory processes. To construct a global normative scenario, hundreds of futurists, scholars, business planners, scientists, and policy makers who work for international organizations, governments, corporations,

non-government organizations, and universities identi ed and rated norms that formed the core of the normative scenario. In order of preference, the participants selected the following top four norms around which to form the scenario: environmental sustainability, plenty, global ethics (the identi ed and accepted ones), and peace. The others in order of preference were health, freedom, access to universal education, equity, preservation of the human species, enlightenment, exciting and meaningful life, self-actualization, longevity, everyone has everything they want, and security.

The body of the normative scenario was composed of the actions that would be required to address the 15 global challenges that had been identi ed through several rounds of global questionnaires to the Millennium Project participants. These actions connected the present world to the normative future of 2050. A scenario review panel was formed of long-term normative-oriented participants of the project to review and improve the draft of the scenario.

The Millennium Project global exploratory scenarios to the year 2025 also used a participatory process of questionnaires and interviews to collect information, but used a computer model with quanti able outputs to assure self consistency. The developments and policies found to be important by the participants provided fodder for the scenarios; these developments and policies were incorporated in each of the projected worlds. The method of incorporating the global model was also novel. Rather than having the model drive the scenario, the scenario drove the model.

As usual, the drafting of exploratory scenarios began with the choice of the principal independent dimensions (axes) that seemed to force the worlds under examination to differ. Future worlds were formed around these choices using techniques described below.

In the next step, these explicit scenarios were used to provide the backdrop for the choice of the values of the exogenous variables in the selected model. Therefore, when the model was run, it s output was consistent with the scenario on which the exogenous variables were based and the model provided quantitative estimates of the value of variables that were then incorporated within the scenario. While several different global models were considered, *International Futures* by Barry Hughes, University of Denver, was selected. It was well documented, relatively easy to use, and was made freely available to the project.

For a more complete description of this approach see http://www.acunu.org/millennium/scenarios/index.html.

The development of scenarios can range from a lengthy and intricate process to an abbreviated workshop. Peter Bishop, for example, has used the SRI/Shell/GBN scenario technique in introductory futures workshops. These workshops, in a four- to six-hour period, can complete a full development sequence of a scenario. The primary purpose of these workshops is to experience the process, not to utilize the actual results of the scenario. During this process, Bishop takes the group through the setting up of scenarios, developing scenario logic, and drawing out scenario implications. By asking focused questions, e.g., what is the most important issue concerning human resources for health care over the next 10 years , what will stay the same about this issue that will limit its alternative futures , and what is changing about this issue that will alter its future , Bishop sets up the scenarios and develops the scenario logic. During the process workshop, participants come to appreciate a wide range of variables that affect the future, as well as the interrelationships among those variables and the existence of alternative, plausible scenarios for the future.

Finally, it is worthwhile to explore one process in depth. This particular methodology is the one developed by The Futures Group.

Preparation

Define the scenario space: a scenario study begins by de ning the domain of interest. Given a clear statement of the domain, analysts list key driving forces thought to be important to the future of the domain. In a study performed by The Futures Group for MITRE Corporation about the social environment of crime, driving forces of law enforcement funding and social attitudes toward crime were de ned as ultimately important. To the degree possible, these driving forces should be independent axes in a scenario space. If three such forces were de ned, the space would be three-dimensional. With two forces, scenario space is two-dimensional. In the law enforcement case, these axes helped de ne four scenarios of interest:

1. high funding, permissive attitudes toward crime;
2. high funding, repressive attitudes toward crime;
3. low funding, permissive attitudes toward crime;
4. low funding, repressive attitudes toward crime.

De ning a large number of alternative worlds is often neither necessary nor desirable. A smaller set of choices that encompass the range of major challenges and opportunities usually suf ces. A few possibilities may need to be excluded as illogical or insuf ciently plausible over the planning horizon. The nal selection of worlds should be suf cient to present a range of opportunities and challenges, but should be small enough in number to handle. Four to ve worlds seems ideal to capture a range of future challenges and opportunities.

Development

Define the key measures: within each scenario, certain key measures are described. These measures might include forces such as economic growth, legislative environment, technology diffusion and proliferation, or competitive

capability, among others. The key measures need to be selected with care. They should have the potential for great impact on the outcome of the scenario; a factor is largely irrelevant if it could develop over a wide spectrum of future values but have little impact on the issue at hand. Every scenario in the set will include projections of the same measures.

De ne the events: this list of events will also appear in each scenario. These events shape the scenarios in several different ways: they can impact the key measures, change the chains of causality that lead from the present to the future, and/or make certain policies more or less likely to work. The probabilities of the events are different in each scenario and depend on their position in the scenario space.

Project the key measures: trend impact analysis is a useful technique for projecting the key measures. Briefly, the historical data for each of the measures is projected using time-series methods. The events, expressed probabilistically, are combined with the extrapolation using Monte Carlo methods to produce a new median forecast and a range of uncertainty. Since events within a scenario impact several measures wherever they are used, they have the same probability; thus, internal consistency is promoted.

Prepare descriptions: given the quantitative forecasts of the measures based on the probabilistic description of the impacting events, many chains of causality become apparent, and cohesive narratives describing the future histories can be prepared.

Reporting and Utilization

Document: in most cases, the best documentation is a simple series of charts and narratives describing the future history represented by each scenario. As thinking surrounding the scenarios is driven farther down in the organization, several levels of documentation for each of the scenarios is often useful. A top-line summary gives readers a quick, intuitive feel for the characteristics of a world from the perspective of a selected future time (say, 2010) – how it developed, and what the decisive events were that caused the world to develop as it did.

Contrast the implications of the alternative worlds: how different are the business decisions and planning goals you would pursue considering each alternative world? What actions and commitments offer your organization the most resilience in the face of these uncertainties?

Testing policies: the range of scenarios can be used to test policies. In any study, a list of alternative actions is prepared. This list may come from the decision makers after reading the scenarios. Each is defined as precisely as possible. Then, using quantitative techniques if possible, the policies are tested in each of the scenarios. When a particular policy produces desirable results in all cases, it is clearly a good policy to pursue. The other scenarios may give rise to contingent policies that can be called on if the circumstances develop that the scenarios depict.

SOME GENERAL GUIDELINES IN SCENARIO CONSTRUCTION

The most useful scenarios are sharply focused. They focus on critical issues facing the organization. The number of issues for consideration and the number of possible scenarios are almost endless. Without a clear direction, the discussion of drivers is difficult to limit. The number of alternative worlds expands exponentially, and the list of variables can become unworkably long. The best defense is to define the focus from the outset. Ask yourself: What planning questions need to be addressed? What variables are most needed in order to address these concerns?

Emphasize qualitative analysis at the start. While numbers and formal models are often valuable sources for understanding future prospects, they can be distracting at the early stages of scenario development. Quantification can be valuable in later stages. Formal models also can provide an effective way of separating the many parts of a complex system for close consideration.

Some argue that trying to select the most likely scenario is inappropriate. The best scenarios reflect many variables and possible turns of events that shape the dynamics of the system under study. Any single scenario that purports to define the most likely particular path through this maze is unlikely to materialize over the years to come. Fortunately, the scenario-building process does not focus on uncovering the most likely forecast but, rather, on identifying the range of feasible outcomes.

Seveso

The Seveso incident focused attention on the risks of chemical manufacture and of the health hazards of tetrachlorodibenzo para-dioxin (TCDD). On July 10th, 1976, the town of Seveso, Italy, near Milan, was the victim of extensive contamination by the most toxic of synthetic chemicals, TCDD. A chemical plant manufacturing trichlorophenol exploded as a result of a safety valve rupture. The explosion sent a cloud of TCDD material over an area of several square kilometers. Although the total amount of TCDD was very small, estimated at

about one kilogram, the chemical is so acutely toxic that the event was catastrophic for the community.

Birds fell from the sky and the town's livestock were slaughtered. Many pregnant women sought abortions rather than risk birth defects associated with TCDD. Many of the town's residents were evacuated. Some 200 residents developed a skin disorder called chloracne, noted as associated with TCDD and observed in US soldiers in Vietnam who handled the herbicidal mixture, *Agent Orange*, which was contaminated with TCDD.

Health studies monitored the residents following the explosion. Increased rates of leukemia, lymphoma, and sarcoma, as well as gall bladder and biliary tract cancer, were observed in the exposed population. There was thorough documentation of TCDD levels in blood and clinical follow-up of the exposed residents. Thus the explosion contributed to medical understanding of the impact of TCDD exposure. The Seveso incident also led to governmental action in the European Community, particularly in relation to hazardous waste sites.

Sierra Club

The Sierra Club is North America's oldest environmental organization. Founded in 1892, it has grown to be the largest membership-based environmental group in the United States with over 550 000 members. Its founder, John Muir, was a Scottish naturalist and writer. Muir championed the protection of the Sierra Nevada with colleague Robert Underwood Johnson, editor of *Century* magazine. Their efforts led to the creation of the Yosemite National Park in 1890.

When the park continued to be threatened by local ranchers seeking grazing rights within the park, Muir founded the Sierra Club, in his words to do something for wildness. He believed that if he could take primarily urban dwellers into the wilds to experience the Sierra Nevada first hand, they would become converts to the cause of wilderness. In its earliest days, the Sierra Club was essentially a hiking club. But it developed a huge influence. Around a legendary campfire at Mariposa Big Tree Grove in Yosemite, Muir persuaded US President Theodore Roosevelt to build a national park system. The Sierra Club has been instrumental in protecting national parks and monuments including the Grand Canyon, Mount Ranier, Kings Canyon, Glacier, Sequoia, Olympic, Death Valley, and Rocky Mountain. In the 1960s, the Sierra Club emerged from its strong California base to build a national organization. It expanded to deal with modern environmental threats such as air and water pollution, as well as it traditional campaigns such as protecting wild rivers from hydroelectric dams. Strong leaders such as Michael McCloskey and David Brower led the Sierra Club to new prominence in the conservation movement. The organization is different from other environmental groups in having an engaged membership. The grassroots, volunteer-based operating style of the Sierra Club has made it a powerful lobbying force in the US. It is subject to the criticism from more radical environmental groups that it is too conservative. Currently, the Sierra Club has chapters across the US, as well as influence through the related, but relatively independent, Sierra Club of Canada.

Small is Beautiful

Small is Beautiful - Economics as if People Mattered was written by E F (Fritz) Schumacher in 1973. The book sold over one million copies in the US alone and contributed substantially to critical analysis of the role of technology, economies of scale as well as the environmental impacts of mega-projects. Schumacher went on to publish *A Guide for the Perplexed*, and a third book, *Good Work*, was published posthumously based on his lectures. E F Schumacher died on September 4th, 1977.

The essence of Schumacher's creative thinking emerged through his work for a report to the government of India in 1962. He advanced the concept of *intermediate technology*, and later founded the Intermediate Technology Development Group in London, UK. Schumacher refined the argument that simpler, people-scaled technologies were more appropriate for the poor in developing countries. He furthered these theories through his work through the 1950s and 1960s as economic advisor to the British coal industry. He also advanced the cause of organic farming through the British Soil Association.

Small is Beautiful in many ways anticipated the doctrine of sustainable development (Brundtland, 1987) as Schumacher did not oppose growth, *per se*, but argued cogently for a kind of growth that did not degrade

living systems, locally or globally, but which, first and foremost met human needs. Smaller mills, mini-plants, operations at human scale provided the template for a radical and profound challenge to prevailing economics and an unquestioned embrace of technology.

ELIZABETH MAY *Canada*

Social Ecology

Social ecology is a small but important environmental movement that integrates the study of human and natural ecosystems through the attempt to understand the relationships between culture and nature. It is often contrasted with *deep ecology* (*see* **Deep Ecology**, Volume 5), of which it is highly critical. Social ecology s starting point is that environmental problems result from social attitudes and practices, therefore the former must be solved by focusing on and changing the latter. An alternative socially and ecologically benign future can be constructed by reharmonizing people s relationship to the natural world, and this will be achieved by reharmonizing their relationship with each other.

The latter may be done through maximizing individual autonomy, eliminating hierarchical relationships (particularly humans over nature and *vice versa*, but also within human societies, such as patriarchy and class oppression) and creating in their stead simple social relationships, including direct, inclusive, economic democracies. The state, capitalism, and giantism are all considered inimical to social ecology s vision of harmonious society, which marries anarchism and ecology drawing particularly on the anarcho-communist legacy of Peter Kropotkin.

Social ecology s most in uential theorist is Murray Bookchin. His critical, holistic worldview places human behavior and institutions within an ecological context that represents social relations as a web of dynamic interrelated systems. But unlike (some interpretations of) deep ecology, Bookchin s approach would not prioritize nature over human society, nor would it dismiss the social aspirations of the Enlightenment Project. It would seek to be neither ecocentric nor anthropocentric, but again unlike deep ecology it sees humankind as evolution s highest expression, i.e., nature s consciousness, so human transformation of nature is natural and desirable.

Social ecologists present speci c utopian visions of a rational, ecological society, where labor is organized into small, human-scale communities without power hierarchies, and where exploitation of nature is minimal and production is environmentally friendly.

Social Impact Assessment (SIA)

Social impact assessment (SIA) is the process of analyzing (predicting, evaluating and re ecting) and managing the intended and unintended consequences on the human environment of planned interventions (policies, programs, plans, and projects) so as to create a more sustainable biophysical and human environment. A short form of this de nition is: SIA is the process of analyzing and managing the intended and unintended consequences of planned interventions on people.

SIA is more than a technique or tool; it is a philosophy about development and democracy, which considers pathologies of development (i.e., harmful impacts), goals of development (such as poverty alleviation or gender equity), and processes of development (e.g., participation, capacity building).

SIA is an overarching framework that considers all potential impacts on humans and their communities including: (1) changes to people s way of life, i.e., how they live, work, play and interact with one another on a day to day basis; (2) changes to their culture, community, neighborhood and local biophysical environment; (3) demands on their political systems, social institutions and community infrastructure; (4) effects on their health and well-being, on their personal and property rights; and on their fears and aspirations for themselves and their families.

The objective of SIA is to ensure that development that does occur maximizes the bene ts and minimizes the costs of development, especially those costs borne by the community and often not adequately taken into account by international development agencies decision-makers, regulatory authorities and developers. By identifying impacts in advance: (1) better decisions can be made about which projects should proceed and how they should proceed; and (2) mitigation measures can be implemented to minimize the harm from a speci c project or project-related activity.

SIA has three different levels of meaning: (1) as a paradigm or eld of research and practice; (2) as a methodology or environmental management instrument; and (3) as a discrete step (or speci c task) within a methodology. SIA is used at these different levels often

with some people failing to appreciate that different meanings or levels exist.

As a paradigm, SIA consists of a body of knowledge, techniques, and values. Various people identify themselves as SIA professionals, or list SIA as a discipline or specialty area. There is a community of scholars engaged in research and practice of SIA. These are people who practice the methodology of SIA and who undertake associated social and environmental research to inform the practice of SIA. As a methodology or instrument, SIA is the process (series of steps) that SIA professionals follow in order to assess and manage social impacts. That process requires substantial interaction with interested and affected peoples. At its narrowest meaning, SIA refers to the task of assessing likely social impacts of a proposed project within an environmental assessment framework (*see* Social Impact Assessment, Volume 4).

Social Learning in the Management of Global Atmospheric Risks

Adam Fenech
Meteorological Service of Canada, Downsview, Canada

Social learning is how humans, as individuals and groups, adopt and spread new concepts, knowledge and skills. It has recently begun to be applied to the process by which societies respond to environmental issues. There was a clear recognition during the late 1980s of the need for a better understanding of how human societies perceive and respond to global environmental change over time, i.e., social learning. Most of the previous understanding of how societies learned re ected the perspectives of a very narrow range of countries and groups, and was focused on key scienti c discoveries and decisions, with little attention to the historic connections between them. There was little critical discussion of what might be appropriately learned from the experience of dealing with other environmental problems, and from the experience of dealing with them in other places or countries. For a general reference, see Rose (1993). This publication is a critical collection of studies on the various kinds of social learning encountered in policy making.

When applying a social learning framework, researchers ask questions such as: Who (individual, organization, country) learned? Was the learning from within the social group, among social groups or from another country? Who was the teacher? Who was the learner? What was learned? What knowledge, experience, or norm was learned? How did this knowledge, experience or norm t or rede ne existing practices, models and decision-making processes? How did the learning occur? Who brought new information to bear on the existing issue? Where did the new information come from? How long did the new information take to formulate into an issue?

A major study applying a social learning framework to the environment has recently been completed under the leadership of William C Clark, Harvard University (Clark et al., *2001). It provides a better understanding of how human societies learned from earlier responses and other countries and organizations in the management of global atmospheric risks. The study applies the social learning framework to global atmospheric risks - namely acid rain, global climate change and stratospheric ozone depletion - from the International Geophysical Year of 1957 to the United Nations Conference on Environment and Development of 1992.*

In the context of environmental issues, Clark's book provides a major entry point into the eld of social learning. From this project, we present a couple of Canadian examples - namely stratospheric ozone depletion and climate change - to illustrate the concept.

SCIENTISTS-TO-SCIENTISTS LEARNING

One form of social learning is a scientist obviously learning from other scientists. What is not so obvious is that, for example, the cadre of Canadian scientists from Environment Canada, who inform and advise the Canadian government, often learn from scientists from other countries about issues, even if other scientists from Canada are already teaching the same message. For example, John Hampson, working at the Canadian Armament Research and Development Establishment (CARDE) in Val Cartier, Quebec in the early 1960s, provided the first statement of concern that human activities could harm the stratospheric ozone layer. Hampson was looking for radiative early-warning signals of incoming missiles, focusing on water vapor from both high-flying aircraft and rockets, arguing that hydrogen species arising from the photochemical dissociation of water could lead to ozone destruction. His work appeared only in CARDE technical reports, which, though widely circulated among both Canadian and American atmospheric and defense research communities, were never taken seriously. Hampson also raised the concern of ozone depletion from

increased air traffic in the atmosphere; yet the Canadian government did not take action until the issue was raised in response to an American research program in the mid 1970s investigating the issue of supersonic transport emissions.

This avenue of learning from scientists-to-scientists illustrates the importance of the teachings being presented in person, either by sending a Canadian scientist to an international gathering to bring the teachings back to Canada, or by bringing the teacher directly to Canada. For example, Sherry Rowland attended a 1975 seminar at York University in Toronto, Ontario, Canada, presenting his theories that developed the mechanism for chlorine catalysis of ozone, and identified chlorofluorocarbons as the largest potential source of stratospheric chlorine. This gave the issue visibility and some initial credibility in Canada.

However, the teaching is not blindly accepted by the learners, since in this case Canada required its own monitoring, modeling and science to confirm the implications and necessity for response.

MEDIA-TO-PUBLIC LEARNING

Another obvious learning channel is from media-to-public. The media acts as a teacher of the Canadian public, creating controversies that spark scientific investigation and government action. The surprise here is that in many instances, the media attention comes from American sources, thus making the US media a teacher and the Canadian public and Canadian media learners. For example, US media coverage of the US Senate Committee hearings of National Aeronautics and Space Administration (NASA) scientist Hansen's concern about the climate change issue sparked Canada's own media to report on the consensus of scientists that climate change was a real concern.

This Canadian experience is repeated in many other countries.

OTHER ASPECTS OF SOCIAL LEARNING

There are many other forms of social learning, ranging from top-down trickle-down arrival of issues, to peer-to-peer exchanges (as exemplified in the scientist-to-scientist model), to bottom-up experiential learning, i.e., the experts are baffled by the kinds of things that ordinary people learn by living every day.

For example, one form of bottom-up learning has garnered increasing interest over the years as the value of traditional or community knowledge has been appreciated and sought out by researchers. Traditional knowledge refers to the understanding of the natural environment that indigenous peoples possess. Traditional knowledge stems from the inherent closeness to the environment that indigenous peoples display by the mere fact of their livelihood and existence being tied to the land, and to what the wilderness offers in terms of food and medicines. Traditional knowledge is linked as well to the passing of knowledge from one generation to another, allowing events in the far past to be passed on through storytelling. Community knowledge refers to the knowledge of a natural resource such as fish or trees by people who live in villages and hamlets. These communities also have knowledge about the changing environment because they are close to the land and wilderness, relying on it for their existence. The value of traditional or community-based knowledge has not been fully realized as there have been no attempts to merge this informal, non-scientific understanding with the rigorous scientific method of current experts. Other approaches are required to fully appreciate the value that traditional and community-based knowledge can provide to understanding our changing environment (*see* Indigenous Knowledge, Peoples and Sustainable Practice, Volume 5).

This new field opens up a myriad questions. Where do people get their information? Who are the champions of new ideas? What gives an idea prominence or acceptability among experts and in the public domain? Is there an optimal model for social learning that we could use to speed up the social learning curve for environmental issues?

Soft Energy Paths

The term *soft energy paths*, was coined by environmental theorist and energy critic Amory Lovins in *Soft Energy Paths* (Lovins, 1977). It can be understood as a reversal of dominant thinking at the time; shifting the focus of energy planning from meeting anticipated demands with increasing energy supplies, to reducing demand through efficiency. Lovins' arguments to leave the hard path of energy planning, a path of brittle, inflexible systems dominated by energy mega-projects, long-transmission lines and bleeding energy losses, were based on the demand side management approach. The key to soft path energy planning is to match energy source to energy demand. A barrel of energy saved has the same value to the economy as a barrel of energy found. Thus, energy efficiency and conservation create energy along the soft path. Lovins called such energy *negawatts*.

According to Lovins:

> The energy problem, according to conventional wisdom, is how to increase energy supplies ••• to meet projected demands. The solution ••• ever more remote and fragile places are to be ransacked, at ever greater risk and cost, for increasingly elusive fuels, which are then to be converted to premium forms (electricity and fluids) in ever more costly, complex centralized and gigantic plants.

To illustrate the inappropriate nature of focusing on supply as opposed to demand, Lovins wrote:

> to ask which is the greenest supply of electricity is somewhat like shopping for the best buy of brandy to burn in your car, or the best buy in antique furniture to burn in your stove. From the end use point of view it is to ask the wrong question.

Lovins' influential work has continued, in partnership with Hunter Lovins, from their base at the Rocky Mountain Institute. Their most recent book, co-authored with Paul Hawken, is *Natural Capitalism*.

Sovereignty and Sovereign States

Karen T Litfin
University of Washington, Seattle, WA, USA

The modern international system is comprised of sovereign states, meaning that each state is in principle legally and constitutionally independent. In practice, however, sovereignty is generally conceived more broadly in terms of some combination of control, autonomy, and authority (Lit n, 1997).

Control, like power, is the ability to produce an effect. Autonomy, or independence, is related to control since the ability to make and implement decisions on one's own requires some degree of power. Authority refers to the recognized right to make rules.

The tension between environmental protection and state sovereignty is evident in the famous Principle 21 of the 1972 Stockholm Declaration, which articulates the state's sovereign right to exploit its own resources and its responsibility not to harm the environment beyond its borders. While sovereignty is most commonly interpreted as a state's right to exercise control and authority within its own territory, the history of international environmental treaty making may be read as an effort by states to strike a balance between rights and responsibilities.

Many international relations scholars believe that sovereignty is being eroded, or at least reconfigured, in the face of growing interdependence, including efforts to address global and transboundary environmental change. The apparent mismatch between nature and the structure

of politics has been expressed in the famous dictum: The Earth is one, but the world is not (World Commission on Environment and Development, 1987). As environmental issues emerged on the international agenda in the early 1970s, some analysts predicted that global ecological interdependence would help bring about the demise of the sovereign state system and its eventual replacement by some far-reaching supranationalism or even world government (Falk, 1971; Ophuls, 1977). More recently, with the proliferation of local and transnational environmental non-governmental organizations in the 1980s, some observers have predicted the erosion of sovereignty from below, with power and authority devolving from sovereign states to the grassroots (Ekins, 1992).

Although the erosion of sovereignty thesis is appealing, a counter argument can be advanced that ecological integrity and state sovereignty, are not necessarily in opposition. One might claim that only the state possesses sufficient authority, resources, and territorial control to enforce environmental regulations (Litfin, 1993). Two important developments since 1970 support this position: the establishment of national environmental agencies throughout the world and the negotiation and implementation of a host of environmental treaties. Moreover, since some challenges to state sovereignty, such as efforts to promote free trade by eliminating environmental restrictions, may be harmful, some would claim that sovereign states are key defenders of the environment (Esty, 1994).

Neither the erosion of sovereignty thesis nor the sovereignty as bulwark thesis, however, does justice to global environmental trends. Both positions conceptualize sovereignty as monolithic rather than multidimensional. Rather, sovereignty should be understood as a historically variable set of aggregated practices. The scope of state autonomy may be narrowed by international and domestic pressures, as the erosion of sovereignty thesis claims, even as the problem solving capacity of states increases, as the second view suggests. Because international environmental responses typically involve trade-offs among autonomy, control, and authority, it is more accurate to say that states engage in sovereignty bargains (Byers, 1991) instead of ceding some monolithic principle of sovereignty. States may voluntarily accept limitations on their decision-making autonomy, for instance, in exchange for a greater ability to protect natural resources either within or beyond their own territorial jurisdiction. Thus, sovereignty appears to be reconfigured, rather than simply eroded, by efforts to address transnational and global environmental change.

Developing countries are particularly sensitive to the possibility that their sovereignty will be compromised by international efforts to address environmental problems. The principle of sovereignty over natural resources, which has engaged the United Nations since 1952, is often cited by developing countries opposed to what they perceive as environmental colonialism. For instance, efforts by industrialized countries to internationalize the issue of tropical deforestation in the 1980s and 1990s met with opposition from developing countries, which claimed sovereign jurisdiction over their natural resources.

The principle of nonintervention, which is key to state sovereignty, is taking on new meanings in light of environmental change. In the past, it was primarily understood in terms of a sovereign state's expectation that foreign powers would not intervene politically and militarily in its own affairs. As we enter the 21st century, the meaning of nonintervention is being renegotiated in the context of global ecological interdependence. When chlorofluorocarbons released in Seattle deplete New Zealand's ozone layer and nuclear fallout from the Chernobyl reactor decimates Scandinavia's reindeer, new norms of nonintervention are required.

As environmental concerns insert themselves increasingly into world politics, and as the political and economic effects of such developments as massive species extinction, climate change, and the globalization of western modes of consumption become increasingly inescapable, sovereignty will be reconfigured in ways that cannot be fully anticipated today.

Sustainability: Human, Social, Economic and Environmental

Robert Goodland
World Bank, Washington, DC, USA

The four main types of sustainability are human, social, economic and environmental. These are de ned and contrasted in Tables 1- 4. It is important to specify which type of sustainability one is dealing with as they are all so different and should not be fused together, although some overlap to a certain extent. Specialists in each eld best deal with these four types of sustainability. For example, social scientists have a lot to say about social sustainability; economists deal with economic sustainability and biophysical specialists deal with environmental sustainability.

A definition of environmental sustainability (ES) has been given by Daly (1973, 1974, 1992, 1996, 1999) and Daly and Cobb (1989):

1. Output rule: Waste emissions from a project or action being considered should be kept within the assimilative capacity of the local environment, without unacceptable degradation of its future waste absorptive capacity or other important services.
2. Input rule:
   - Renewable resources: (e.g., forest, fish) harvest rates of renewable resource inputs must be kept within regenerative capacities of the natural system that generates them.
   - Non-renewables: depletion rates of non-renewable resource inputs should be set below the historical rate at which renewable substitutes were developed by human invention and investment according to the Serafian quasi-sustainability rule (see below). An easily calculable portion of the proceeds from liquidating non-renewables should be allocated to the attainment of sustainable substitutes.

SERAFIAN QUASI-SUSTAINABILITY RULE OF NON-RENEWABLES

The Serafian rule pertains to non-renewable resources, such as fossil fuels and other minerals, but also to renewables to the extent they are being mined. It states that their owners may enjoy part of the proceeds from their liquidation as income, which they can devote to consumption. The remainder, a user cost, should be reinvested to produce income that would continue after the resource has been exhausted. This method essentially estimates income from sales of an exhaustible resource. It has been used as a normative rule for quasi-sustainability, whereby the user cost should be reinvested, not in any asset that would produce future income, but specifically to produce renewable substitutes for the asset being depleted. The user cost from depletable resources has to be invested specifically in

Table 1 Comparison of Human, Social, Economic and Environmental Sustainability: Human Sustainability

• Human sustainability means maintaining human capital. Human capital is a private good of individuals, rather than between individuals or societies. The health, education, skills, knowledge, leadership and access to services constitute human capital. Investments in education, health, and nutrition of individuals have become accepted as part of economic development
• As human life-span is relatively short and finite (unlike institutions) human sustainability needs continual maintenance by investments throughout one's lifetime
• Promoting maternal health and nutrition, safe birthing and infant and early childhood care fosters the start of human sustainability. Human sustainability needs 2–3 decades of investment in education and apprenticeship to realize some of the potential that each individual contains. Adult education and skills acquisition, preventive and curative health care may equal or exceed formal education costs
• Human capital is not being maintained. Overpopulation is intensifying and is the main dissipative structure worsening per capita indices. That is far graver than overcapitalizing education so that laborers have PhDs

Table 2 Comparison of Human, Social, Economic and Environmental Sustainability: Social Sustainability

- Social sustainability means maintaining social capital. Social capital is investments and services that create the basic framework for society. It lowers the cost of working together and facilitates cooperation: trust lowers transaction costs. Only systematic community participation and strong civil society, including government can achieve this. Cohesion of community for mutual benefit, connectedness between groups of people, reciprocity, tolerance, compassion, patience, forbearance, fellowship, love, commonly accepted standards of honesty, discipline and ethics. Commonly shared rules, laws, and information (libraries, film, and diskettes) promote social sustainability
- Shared values constitute the part of social capital least subject to rigorous measurement, but essential for social sustainability. Social capital is undercapitalized, hence the high levels of violence and mistrust
- Social (sometimes called moral) capital requires maintenance and replenishment by shared values and equal rights, and by community, religious and cultural interactions. Without such care it depreciates as surely as does physical capital. The creation and maintenance of social capital, as needed for social sustainability, is not yet adequately recognized. Western-style capitalism can weaken social capital to the extent it promotes competition and individualism over cooperation and community
- Violence is a massive social cost incurred in some societies because of inadequate investment in social capital. Violence and social breakdown can be the most severe constraint to sustainability

Table 3 Comparison of Human, Social, Economic and Environmental Sustainability: Economic Sustainability

- Economic capital should be maintained. The widely accepted definition of economic sustainability is maintenance of capital, or keeping capital intact. Thus Hicks's definition of income–the amount one can consume during a period and still be as well off at the end of the period–can define economic sustainability, as it devolves on consuming value-added (interest), rather than capital
- Economic and manufactured capital is substitutable. There is much overcapitalization of manufactured capital, such as too many fishing boats and sawmills chasing declining fish stocks and forests
- Historically, economics has rarely been concerned with natural capital (NC) (e.g., intact forests, healthy air). To the traditional economic criteria of allocation and efficiency must now be added a third, that of scale (Daly, 1992). The scale criterion would constrain throughput growth–the flow of material and energy (NC) from environmental sources to sinks
- Economics approaches value things in money terms, and have major problems valuing NC, intangible, intergenerational, and especially common-access resources, such as air. Because people and irreversibles are at stake, economic policy needs to use anticipation and the precautionary principle routinely, and should err on the side of caution in the face of uncertainty and risk

Table 4 Comparison of Human, Social, Economic and Environmental Sustainability: Environmental Sustainability (ES)

- Although ES is needed by humans and originated because of social concerns, ES itself seeks to improve human welfare by protecting NC. As contrasted with economic capital, NC consists of water, land, air, minerals and ecosystem services, hence much is converted to manufactured or economic capital. Environment includes the sources of raw materials used for human needs, and ensuring that sink capacities recycling human wastes are not exceeded, in order to prevent harm to humans
- Humanity must learn to live within the limitations of the biophysical environment. ES means NC must be maintained, both as a provider of inputs (sources), and as a sink for wastes. This means holding the scale of the human economic subsystem (= population $\times$ consumption, at any given level of technology) to within the biophysical limits of the overall ecosystem on which it depends. ES needs sustainable consumption by a stable population
- On the sink side, this translates into holding waste emissions within the assimilative capacity of the environment without impairing it
- On the source side, harvest rates of renewables must be kept within regeneration rates
- Technology can promote or demote ES. Non-renewables cannot be made sustainable, but quasi-ES can be approached for non-renewables by holding their depletion rates equal to the rate at which renewable substitutes are created. There are no substitutes for most environmental services, and there is much irreversibility if they are damaged

replacements for what is being depleted in order to reach sustainability, and must not be invested in any other venture – no matter how profitable. For non-renewable energy, a future acceptable rate of extraction of the non-renewable resource can be based on the historic rate at which improved efficiency, substitution and re-use became available. These calculations show the folly of relying on technological optimism, rather than on some historic track record.

CAUSES OF UNSUSTAINABILITY

When the human economic subsystem was small, the regenerative and assimilative capacities of the environment appeared infinite. We are now painfully learning that environmental sources and sinks are finite. Originally, these capacities were very large, but the scale of the human economy has exceeded them. Source and sink capacities have now become limited. As economics deals only with scarcities, in the past source and sink capacities of the environment did not have to be taken into account. Conventional economists still hope or claim that economic growth can be infinite or at least that we are not yet reaching limits to growth.

Theology

In the context of human–environment relations, there are four kinds of theology:

Ecotheology is theological reflection focused on the relationship of faith to ecological wellbeing and social justice.

Dominion theology refers to theological worldviews that perceive humans as being placed by God at the top of a pyramid of value with all other creation made expressly for the use of humanity and over which humans could exercise dominion or control.

Stewardship theology is a challenge to traditional dominion theology that argues that humanity's place within creation is not one of authority but one of responsibility to care and nurture the Earth on behalf of the creator.

Process theology is a school of theology that emphasizes the inextricable linkages of humans within the entirety of the creation.

DAVID G HALLMAN *Canada*

Theories of Health and Environment

Trevor Hancock
Trevor Hancock Inc., Kleinburg, Canada

Early theories of health - still commonly found in many cultures throughout the world - understood health as the result of the characteristics and behavior of the individual and his or her relationship with the community, nature and the spirits or gods. The role of healers was to re-establish balance and to drive out evil spirits. Three great healing traditions (Greco-Arabic, Indian [Ayurvedic] and Chinese) share common ideas about maintaining equilibrium among the humors, taking into account environmental factors, and addressing personal factors and the spiritual dimension.

In Europe, from the 2nd century AD until the 19th century, the miasmic theory that atmospheric and environmental conditions were responsible for the transmission of epidemic diseases competed with the contagion theory, which suggested that transmission was via minute infective agents or spores, and the theory of individual predisposition. While passive acceptance of environmental conditions marked much of this period, activist Boards of Health first appeared in Northern Italy in the 15th century. Later, the social hygiene movement of the 18th century laid the groundwork for the emergence of the public health movement in the early 19th century.

The public health approach addressed environmental sanitation and living and working conditions that had been worsened by the industrialization and urbanization of the 19th century. At the same time, improved nutrition, education and other social and economic development factors - in turn, based upon exploitation of the earth's resources - contributed to a signi cant increase in life

expectancy and health in the 19th and early 20th centuries. But with the identi cation of bacteria in the 1870s and the development of effective vaccines and, in the 1930s, antibiotics, the pendulum swung toward a medical model of health focused on the individual and the treatment of speci c diseases. This has been the dominant paradigm for most of the past 100 years.

Beginning in the 1970s, however, there has been a growing awareness that healing and caring for the individual is much more than just xing the body, and that the determinants of health are much broader than simply the provision of medical care. In addition to recognizing that much of the improvement in health in the 19th and 20th centuries has been due to social and economic development, the view from space has helped us to understand that we all share a small and fragile planet and that our health is inextricably linked to the health of its ecosystems.

Three powerful new, and complementary, models that are emerging in the western world in many ways represent a return to the public health model of the 19th century and to even earlier theories of health as balance within the person, balance between the individual and other people and balance between humans and nature. These three models - holistic medicine, population health and ecosystem health - represent a new synthesis, a new theory of health with roots that are thousands of years old.

INTRODUCTION

It seems that every culture and every period in history has a theory of health – what it is, what determines health and how to achieve it. The by-now classical World Health Organisation (WHO) definition of health (*see* **WHO (World Health Organization)**, Volume 4) as a state of complete physical, mental and social well-being and not merely the absence of disease or in rmity is revealing both for what it says and for what it does not say. First, perfect health, i.e., a state of complete physical, mental and social well-being, may be a goal to be striven for, but it is probably unattainable. Second, if health is more than the absence of disease, then the prevention and treatment of disease alone will never be enough to achieve this. This suggests that the health care system, with its focus on the treatment and, to a lesser extent, the prevention of disease, is a necessary but not suf cient determinant of health.

Third, and perhaps most revealing in the context of this encyclopedia, is that the focus of the WHO de nition is on the individual (physical and mental well-being) and their social context (social well-being) but there is no reference to the environmental or ecological context. This probably re ects the tenor of the time, when there was little or no awareness of global change and what we now think of as *ecosystem health* (*see* **Ecosystem Health**, Volume 4). But today we recognize the importance of health not only as a human attribute but as an attribute of living systems as a whole, from local ecosystems to the global ecosystem that some call Gaia (Lovelock, 1979) (*see* **Gaia**, Volume 2). Such systems need to be balanced and in harmony, just as our own internal systems do, a process known as *homeostasis*. When our human systems are in such a state of balance, we are said to be healthy; health has become a useful metaphor for such a condition in ecosystems as well. Perhaps today, then, we would extend the WHO de nition somewhat to state that health is a state of complete physical, mental, social and ecological wellbeing ••• . In doing so, we would be returning to some much older theories of health.

HISTORICAL AND CULTURAL PERSPECTIVES

The concept that humans are somehow separate from, and superior to, the environment is a relatively recent one. It is primarily a product of Western thought in the past few hundred years, and has been particularly apparent in the last hundred. But for much of human history, humans have understood themselves to be a part of, and subject to the whims of, nature, often personi ed as some form of spirit or god. Good health resulted from living a good life in harmony with nature which included appeasing the gods and ill health was seen as the result of a loss of that harmony, a loss of balance, or a punishment from the gods. Healing then became a matter of restoring harmony and balance, in one s self, with the community, with nature and with the gods. Healers or shamans used a wide array of naturally occurring healing substances, and as well communicated with the spirits or gods in an attempt to restore balance and harmony and to drive out evil spirits. Such beliefs and cultural practices can still be found in many parts of the world, and in our multi-cultural societies can also be found in many Western societies.

Three great ancient healing traditions have been important in the evolution of modern understanding of health and healing, and the relationship between health and the environment. Shahi *et al.* (1997) argue that the fundamental beliefs and practices of those three traditions Greco-Arabic, Indian (Ayurvedic) and Chinese share much in common and that Evidence exists of signi cant cross-fertilization between these three great humoral traditions of medicine, with the exchange of ideas and products . Commonalities include:

- health is dependent on maintaining equilibrium among the *humors* (earth, water, re and, depending on the tradition, air, ether, wood and metal);
- this equilibrium is affected by such personal factors as age, sex, temperament, food consumption and nutritional status;
- all three systems took into account environmental factors such as the seasons, the cardinal directions (north,

south, east and west), the cycle of birth, growth and death and the condition of places, as well as emanations (*miasmas*) from decaying organic materials, from swamps and from the earth (miasma is a Greek word for pollution);
- there is an all embracing order of things which aligns the organization of human and other life, society and the universe, balancing polar opposites such as light/dark, moist/dry, heat/cold, etc.;
- many of the therapeutic interventions focused on modifying the patient's diet and surroundings, as well as using a wide range of medications (Shahi *et al.*, 1997).

The Greeks, for example, fully understood the need to balance both healthy living and healing, or treatment. Thus the Greek god of medicine, Asclepius, son of Apollo, had two daughters: Panakeia, the goddess of treatment (from whom we get the word *panacea*) and Hygeia, the goddess of healthy living, from whom we get the word *hygiene*.

A key figure is that of Hippocrates (460–377 BC), the Greek Father of Medicine, whose school was founded on the island of Kos. (Many physicians today still take the Hippocratic Oath on graduating.) Among the many works attributed to Hippocrates is one entitled Airs, Waters, Places , in which the relationship between health and the environment is discussed. It was felt important to pay attention to the quality of the air, the direction and qualities of the winds, the quality of the water, the local topography and climate and other factors, in choosing a place to live that would be healthy. Here we have a clear example of the way in which human health and human settlements were seen to be related to each other and to the quality of their environment. Indeed, by their commitment to natural law and to observation, the Greek physicians laid the groundwork for the science of medicine.

The last great physician in this tradition was Galen, who lived in the 2nd century AD. Writing about Galen, noting that three major factors were then believed to contribute to ill health – atmospheric corruption (miasma), individual predisposition and contagion – Winslow (1943) observed that:

> Here in the 2nd century AD were the three factors ••• which were to dominate scientific thinking up to the age of Pasteur. For more than 1600 years the history of epidemiology is a story of a shifting emphasis on these three basic conceptions.

The Romans were also well aware of the relationship between the environment and health, undertaking massive public works projects to provide clean water and to remove human wastes in their towns and cities. But with the coming of the Dark Ages in Europe, much of this knowledge of hygiene and healing was lost, although kept alive in the Islamic world, from where this knowledge was gradually re-acquired in the Middle Ages.

THE PUBLIC HEALTH APPROACH

The Renaissance, which flowered in northern Italy and spread across Europe in the 15th century, brought with it a renaissance of public health as well. Boards of Health were established in most of the major city-states of Northern Italy in the 15th century, primarily in response to epidemics of plague, a bacterial disease with a high mortality rate that is spread by the bite of infected fleas from rats to humans, as well as directly from humans to each other. Unhygienic and over-crowded living conditions undoubtedly hastened the spread of this dreadful disease. (For an excellent review of the broad historical sweep of this and other major diseases, their environmental and social roots and their impact on historical events such as the conquest of the Americas, see McNeill, 1976).

By the 16th century, the Boards' responsibilities included such diverse areas as hygiene, sanitation, food quality, burials, the regulation of hospitals, physicians and apothecaries and the control of prostitutes and vagrants. They had broad powers to regulate public gatherings, enforce quarantine laws, issue health passes and carry out inspections (Cipolla, 1976).

The public health approach of these times was still based primarily on the miasmic theory – the belief in the role played by atmospheric and environmental conditions in the transmission of epidemic diseases. Its rival, the contagion theory, was championed by Jirolamo Fracastoro (1484–1553). He suggested an alternative hypothesis, that epidemic spread of disease occurred as a result of the transmission of minute infective agents or spores from person to person either directly, via intermediaries, or through the air (Shahi *et al.*, 1997), although these agents were thought to be chemical, not biological in nature – bacteria had yet to be discovered.

Over time, these two theories became synthesized. But throughout this period from the Dark Ages to the 18th century, with some notable exceptions such as the activist Boards of Health in Renaissance Italy, the general attitude seems to have been passive – the environment was a given, and little could be done to change its impact on health.

However, with the beginnings of the scientific revolution in the 17th century and the Age of Enlightenment in Europe in the 18th century came a more critical, rationalist and activist ideology. This new activism, when applied to public health, became known as *social hygiene*. Its leading proponent was the Abbe Claude Fleury (1640–1723). This movement was the precursor to, and provided the foundation for, the public health movement of the 19th century.

Perhaps the greatest exponent of public health in the 18th century was Johann Peter Frank, Director-General of Public Health in Austrian Lombardy (Northern Italy) from 1786. This pioneer of social medicine established

hygiene as a systematic science and advocated the creation of state medicine. Frank taught that the greatest wealth of a state lies in its subjects, who should be as numerous, healthy and productive as possible ••• (Frank, 1976). Frank was concerned with the harmful impact of Man upon his environment. He had a healthy scepticism about the ability of physicians and hospitals to influence the health of a population, and he was concerned with the deleterious effect upon health that a poor life style had, whether that lifestyle was chosen or imposed. He saw the role of public health as helping to maintain the security and stability of the state, which he viewed as a benign and paternalistic protector of its people.

The need to maintain the security and stability of the state was also of great concern to Edwin Chadwick, the English lawyer and public servant who is seen as the father of modern public health. In an article written in 1828, Chadwick contended that the environment must influence health and wellbeing, which in turn are the pillars of social stability, and that the best means to ensure social stability was for the state to promote health and wellbeing by improving the environment (Ringen, 1979).

Chadwick was one of the chief architects of the new Poor Law of 1834, which helped make industrialization possible by establishing the mobility of labor. But within a few years Chadwick became concerned that the poor social and health conditions of the laboring class might result in unrest, even revolution. Thus the famous Sanitary Report of 1842, which examined the health conditions of the laboring class, while undoubtedly sparked by an humanitarian concern, was also concerned with improving conditions enough to avert serious social unrest. Frederick Engels powerfully portrayed those conditions in 1845, when he described Manchester's River Irk as:

> a narrow, coal-black, foul-smelling stream ••• in dry weather, a long string of the most disgusting, blackish-green slime pools are left standing ••• from the depths of which bubbles of miasmatic gas constantly arise and give forth a stench unendurable even on the bridge 40 or 50 feet above the surface of the stream.
>
> (quoted in Girouard, 1985)

while Hippolyte Taine wrote of his visit to Manchester in 1859:

> Earth and air seem impregnated with fog and soot. The factories extend their flanks of foul brick one after another, bare, with shutterless windows, like economical and colossal prisons ••• through half-open windows we could see wretched rooms at ground level, or often below the damp earth's surface. Masses of livid children, dirty and flabby of flesh, crowd each threshold and breathe the vile air of the street, less vile than that within •••.
>
> (quoted in Girouard, 1985)

It was environmental conditions such as these that led to the British government establishing the Health of Towns Commission in 1843. Again led by Chadwick, the Commission's work led to the adoption of the sanitary idea and to the establishment of public health measures such as housing standards, sewer systems, hygiene regulations and proper public water supplies. A Health of Towns Association, established in 1844, with branches all over Britain, supported the Commission's work.

> The work of the Health of Towns Association in pressing for the application of the sanitary idea and its insertion into policy making had a dramatic effect on public health in Britain in a comparatively short space of time.
>
> (Ashton, 1992)

Thus by the middle of the 19th century, the contribution of filthy environments and appalling living and working conditions to the health of the population was well established, along with a strong and active public movement to support social and political intervention to modify the environment. Its apogee, perhaps, came in the 1870s when Sir Benjamin Ward Richardson, a disciple of Chadwick, marked the passage of the great Public Health Act of 1875 by describing his vision of a city of health:

> a community so circumstanced and so maintained by the exercise of its own free will, guided by scientific knowledge, that in it the perfection of sanitary results will be approached, if not actually realized, in the co-existence of the lowest possible general mortality with the highest possible individual longevity.
>
> (Richardson, 1875)

But through one of those ironic twists of fate, the 1870s were not only the time of the Great Public Health Act and of Benjamin Ward Richardson's vision of a healthier city, but were also the time at which the bacteriologists were announcing many of their most exciting discoveries about bacteria, insect vectors, animal reservoirs of disease and human carriers and were developing effective vaccines and anti-toxins. These discoveries ushered in a very different theory of health, one that was to become the dominant model in much of the world over the next century.

THE MEDICAL MODEL OF HEALTH

Throughout history, the Hygeian or public health and Panakeian or medical/therapeutic models have co-existed and contended. For much of the 19th century, the Hygeian model was dominant. But with the identification of bacteria and the refinement of biological and clinical research, the emphasis shifted towards the Panakeian model, with its emphasis on finding the specific cause of disease in bacteria, in nutritional and metabolic disorders, in biochemical and molecular changes. In this medical model, health is seen primarily as the absence of disease.

The medical model has become powerful because it has been allied to the scientific method and the dominance

of Western culture and civilization in the past couple of hundred years. This analytic model has focused its increasingly narrow attention on organs, on cells, on microorganisms, on genes, and on molecules as causes of disease. But this focus has also tended to exclude the broader environmental, social and economic factors at play. In essence, the medical model is a reactive model, looking for disease and then seeking a treatment for it (a *pathogenic model*) rather than seeking to understand what determines good health and how to maintain and improve it (a *salutogenic model*, as Antonovsky (1978) termed it).

At its simplest, the medical model sees a single cause – the measles virus, for example – and a single effect – the disease of measles. This simple cause and effect model lies behind the search for specific treatments for specific diseases, a search that has had some remarkable successes. But it also quickly became apparent that simple exposure to a pathogenic organism such as the measles virus, while necessary for the disease to occur, was not sufficient. The epidemiological triangle of agent, host and environment, sought to explain this by identifying differences in the environment (which might affect transmissibility, for example), in the host (who might be resistant) or in the agent (which might differ in terms of dose, virulence, etc.). Further complicating matters is that some causes (smoking, for example) might have multiple effects (several forms of cancer, heart disease, stroke, respiratory disease, low birth weight and many other diseases) while some diseases (heart disease, for example) might have multiple causes (inherited susceptibility, high blood pressure, smoking, high cholesterol levels, infection, lack of exercise and other factors).

The medical model of health has had some spectacular successes, particularly in the development of antitoxins and vaccines to protect against infectious disease (the eradication of the scourge of smallpox is a high point), antibiotics to treat bacterial (but not viral) disease, medications to control high blood pressure and many other diseases, and some forms of cancer therapy. In recent years a vast array of chemotherapeutic agents has been developed for all manner of minor and major, chronic and acute, physical and mental health problems, as well as surgical treatments for both major and minor health problems. In addition, Western medicine has shown itself to be remarkably effective at dealing with traumatic injuries that in the past would have been fatal. Indeed, so widespread and pervasive has this model become that the concept of medicalization has been developed to describe the extent to which medicine infiltrates and even distorts our lives and our societies. Illich (1976) has famously discussed *iatrogenesis* (doctor-caused disease) as not simply clinical disease resulting from errors, unanticipated side effects and the over-use of diagnostic and therapeutic techniques, but also has described social and cultural iatrogenesis – the medicalization of many normal parts of life such as feelings of dis-ease, validation of disability or work and school absenteeism, or the processes of birth and death.

This growth in modern Western medicine has also occurred at the same time as a massive increase in life expectancy, which for all its faults remains the most commonly used overall index of health. Life expectancy at birth for women in Canada, for example, increased from 43.8 years in 1871 to 76.4 years in 1971 (Bourbeau and Legare, 1982), while in Chile male life expectancy at birth increased from 29 years around 1910 to 72 years in 1998 and female life expectancy at birth in Japan in that same period increased from 43 to 83 years (WHO, 1999). Globally, life expectancy at birth has increased from 48 years in 1955 to more than 65 years in 1995, and is projected to increase to 73 years by 2025 (WHO, 1998). On a regional basis, average life expectancy at birth in 1997 ranged from 53 in the African Region of WHO to 72 in the European region and 73 in the American region. The largest increases in life expectancy at birth between 1975 and 1997 were found in the Eastern Mediterranean region (12 years) and the Southeast Asian region (11 years), with more modest but still substantial gains of 6–7 years in the African, American and Western Pacific regions, while the European region posted a gain of 2 years (WHO, 1998).

As a result, there has been a widespread belief that our long lives and better health are attributable to modern Western medicine, which has only served to strengthen the dominance of the medical model. However, since the 1970s new theories of health have been emerging, rooted in a questioning of the efficacy of the medical model and in a more salutogenic orientation.

NEW PERSPECTIVES

One aspect of the questioning of the medical model comes from the psychological and social sciences. For while the medical model of health focuses mainly on the bio-physiological dimension, there is also a psycho-social dimension to disease, a perception that we call *illness*. Moreover, people may feel ill without there being any evidence of bio-physical disease. Norman White, a Canadian psychiatrist, has suggested a bi-axial model, one axis representing the biophysical spectrum from disease to physiological health, the second axis representing the psycho-social spectrum from illness to a sense of well-being. In such a model, people may be physiologically healthy but psychosocially ill, or they may have physiological disease but feel well (undiagnosed high blood pressure would be a good example of this). We are not simply biological systems, we are also psycho-social beings, and theories of health must recognize this fact.

A second powerful response to the power of the medical model – and its failings – has been the (re)-emergence of a more holistic model of health that pays greater attention to the relationship between body, mind and spirit, an area generally neglected by modern Western medicine. This has involved a dramatic growth in the desire of knowledgeable and empowered consumers to be much more involved in their own health care, both through self-care and mutual support and through an increased emphasis on healthy living and the personal use of natural therapies. At the same time practitioners of holistic, alternative or complementary medicine in the West have been rediscovering and re-applying insights and wisdom from traditional healing practices rooted primarily in Eastern philosophies. Naturopathic, homeopathic and ayurvedic methods, acupuncture, shiatsu, massage, meditation and many other healing modalities have been growing rapidly in the West in the past few decades, in response to the growing public disillusion with the hard science values and practice of modern Western medicine. Their emphasis on healthy living, on caring, on re-establishing balance and harmony and on the use of natural remedies links them not only to the ancient healing traditions discussed earlier, but to modern concepts of wellness and ecosystem health.

While holistic medicine was and is a critique of the clinical aspects of the medical model, a critique of the role of medicine in improving health was also developing in the 1960s and early 1970s. Thomas McKeown – Professor of Social and Preventive Medicine at the University of Birmingham in England – began to inquire into the factors that led to improved health in England and Wales in the 19th century. His answers were somewhat surprising; he showed that the major factors leading to improved health had been improved nutrition, improved hygiene, limitations in family size (all of these rooted in economic and social development) and the development of vaccines in the late 19th and early 20th century and of antibiotics in the 1930s (McKeown, 1979). In short, McKeown found that improvements in health had not been primarily due to improvements in medical care, but to the combination of social and economic development.

McKeown's work formed the basis of a seminal Canadian report in 1974 that, for the first time, suggested that a national, and for that matter world-wide, policy focus on provision of health care was insufficient. The Lalonde Report – *A New Perspective on the Health of Canadians* – proposed the health field concept in which four factors – environment (physical and social), lifestyle, health care organization and human biology – were the key determinants of health (Lalonde, 1974). Importantly, the Lalonde Report proposed that major improvements in the health of Canadians will result primarily from changing lifestyles, improving our environments, and advances in our understanding of human biology . The Lalonde Report was influential not only in Canada but also in the US and in Europe, where it spawned similar reports in the years that followed. Over the past 25 years, the analysis has been refined.

The initial emphasis – and still a strong focus today – was on lifestyle. One estimate suggested that up to 50% of preventable mortality was attributable to lifestyle diseases, which were sometimes called diseases of choice. The implication was that if only people would make healthy and wise choices, much ill-health and premature death could be avoided. The wellness movement that emerged in the 1970s focused on the individual's personal responsibility to avoid smoking and excessive drinking, to improve fitness and nutrition, to learn stress management and to develop environmental awareness and a sense of spiritual and emotional well-being (Ardell, 1977). However, critics of this approach, while acknowledging that healthy choices are important, pointed out that environmental, social, economic and cultural circumstances and our living and working conditions shape and sometimes constrain those choices. Over time, this led to the emergence of the concept of *population health*.

Taking their cue from the work of McKeown, advocates of population health (e.g., Evans *et al.*, 1994) have pointed to the significance of the economic and social determinants of health, drawing attention in particular to the importance of poverty and inequality and the influence of social status on health. This in turn has been linked to factors such as self-esteem and sense of self-worth, to the influence of the social hierarchy and of the degree of control over working conditions, and to the relationship between the mind and the body's immune system, a field of study known as *psycho-neuro-immunology*. The research findings suggest that such factors may be as important as conventional risk factors such as smoking, diet and exercise in the development of heart disease. For example, the 1999 World Health Report cites evidence that suggests that the most important factors that have led to the reduction in mortality between 1960 and 1990, based on data from 115 low and middle income countries, were ascribable to the generation and utilization of new knowledge (which includes but is much more than medical knowledge and technology), improvements in the educational level of women and improved income, in that order (Wang *et al.*, 1999, cited in WHO, 1999). However, while strong on the social and socio-economic factors, the population health approach is curiously silent on the influence of the built and natural physical environments on population health status.

The neglect of the built environment within which the social processes of population health occur is particularly unfortunate because the most significant human environment today is the built environment. Globally, half of humanity now lives in urban settlements, while in the

developed world some 80% of the population is urbanized. Moreover, humans spend most of their time indoors, especially in the developed world. In North America, people are indoors almost 90% of the time and in their cars 5% of the time, leaving only 5% when they are outdoors (Leech *et al.*, 1996). The built environment is a human artifact comprising both a physical and a social environment, and it constitutes the human ecosystem. Understanding human health increasingly means understanding the effects of complex urban physical and social environments and processes upon the health of urban residents. It also means understanding how the urban way of life affects the health of the wider natural ecosystems of which they are a part.

The ecological perspective on health has emerged from the growing importance of ecology, and from the growing awareness of global change and its health implications; human health is inextricably linked to ecosystem health. The view of earth from space has made it apparent, as never before, that we are bound to and part of a fragile and beautiful place, a living planet that some call Gaia. At the same time, this global perspective and the modern science of ecology has enabled us to understand how potent is our power to affect the global life support systems on which we depend.

For while the increase in life expectancy and other measures of health that we have experienced may seem to be due primarily to the dramatic social and economic development we have undergone, this development has in turn been based upon industrialism s exploitation of the earth s resources notably energy, forests, soils, minerals and the oceans and the accompanying widespread pollution of our environment, indeed of the planet as a whole. Thus, in a very real sense, our current high level of health and long lives have been purchased at the expense of the environment.

But global change is not without cost (see McMichael, 1993, or Chivian *et al.*, 1993, for good overviews of the health implications of global change) (*see* **Environmental Change and Human Health: Extending the Sustainability Agenda**, Volume 3). Global warming, ozone depletion, acid rain and other climate and atmospheric changes threaten our health; global warming in particular will increase the range of the mosquitoes that spread malaria, dengue fever and other diseases, as well as the distribution of other disease vectors. More severe storms, oods and droughts will also add to the burden of infectious diseases as well as causing hunger, malnutrition and trauma. The depletion of such renewable resources as sheries, forests, topsoil and fresh water aquifers threatens our food supplies and may cause both malnutrition and mass migration, with all its attendant misery, diseases and deaths. Environmental pollution and ecotoxicity the widespread contamination of entire ecosystems and food chains with persistent organic pollutants (POPs) has made it apparent, as the North American Indian Chief, Seattle, is reputed to have remarked more than 100 years ago, that we are all part of the web of life, and whatever we do to the web of life, we do to ourselves . We simply cannot tell what a lifelong exposure to low levels of multiple POPs will mean for the health and well-being of today s infants, nor for the health of other species that are equally exposed. This applies also to the loss of habitat that we are causing and the accompanying loss of biodiversity as a result of a human-created mass extinction; we do not know how many strands of the web of life we dare sever. And the massive increase in trade and travel that has accompanied globalization has meant that exotic diseases (such as West Nile fever, spread by birds and mosquitoes) or exotic vectors (such as the Asian Tiger mosquito, a hardy mosquito that has been introduced into the USA and that spreads dengue and yellow fever) will become more widespread.

There is thus a growing awareness that human health is dependent upon ecosystem health, and even a concern that human health can no longer be sustained if the industrial and economic growth that has been the basis of improved health undermines the ultimate determinants of health the Earth s life support systems and natural resources (World Resources Institute, 2000).

A NEW SYNTHESIS

Any modern theory of health thus has to take into account and integrate the bio-medical model (including its complementary or alternative versions), the wellness and lifestyle approach, and the social, economic, built and natural environmental determinants of health.

In his depiction of a sane, humane and ecological society, the British futurist Robertson (1978) described sanity as balance within the individual, humanity as balance between the individual and other people in their communities and around the world, and ecology as balance between humans and nature. These three concepts in many ways represent the three broad themes in the re-conceptualization of health described above that have emerged in the late 20th century: holistic medicine and wellness, with its focus on the individual s balance and harmony; population health, with its focus on social conditions and processes; and ecosystem health, with its focus on the relationship between human health and the health of the planet. They all have roots in much earlier models of health.

- A focus on holistic medicine and wellness harkens back to much older views of the importance of diet and nutrition, of maintaining balance in leading a healthy life, and in forms of treatment which address the body, mind and spirit together. It might perhaps be considered part of the Panakeian tradition.

- Improved living and working conditions were a major factor in improving health in the 19th century, and population health reminds us that social and economic development remains important today, while the modern-day Healthy Cities and Communities movement takes its inspiration directly from its Victorian predecessors. As in Hippocrates' time, we still have to be concerned with airs, waters and places, with the quality of our human settlements and our buildings. Maintaining and improving urban and suburban environments and the social and physical quality of the homes, schools, workplaces, institutions and other settings where we spend most of our time remains an important task for those concerned with public health. This is the Hygeian tradition.
- We are rediscovering that in order to be healthy we have to be in tune with nature, both at a local level and globally. As with the re-emergence of holistic medicine, this is in some respects a return to our roots, to an awareness of our place within, rather than apart from and superior to, nature. Healthy people can only exist within healthy communities and on a healthy planet. This might be considered the Gaian tradition.

A synthesis of these three concepts may lead to a new understanding of health. What follows is a model of the human ecosystem that provides such a synthesis, a theory of health for the 21st century that seeks to integrate these new theories of health.

AN ECOLOGICAL MODEL OF HEALTH

All models reflect the contemporary intellectual and cultural context in which they are created, and, of course, all models are wrong, in the sense that they are only a model of reality, not reality itself, and that they reflect the personal context of those who create the model, which in turn reflects the cultural, social and intellectual context of their times. That having been said, a modern theory of health has to incorporate the biomedical, holistic medicine, wellness, population health, and ecosystem health perspectives. The Mandala of Health (Hancock and Perkins, 1985; Hancock, 1985) is one such model (see Figure 1), reflecting our current understanding of the elements of the human ecosystem that determine health. Developed in the early 1980s to explain the new public health approach in the City of Toronto in Canada, it builds upon and expands the four health fields of the Lalonde Report.

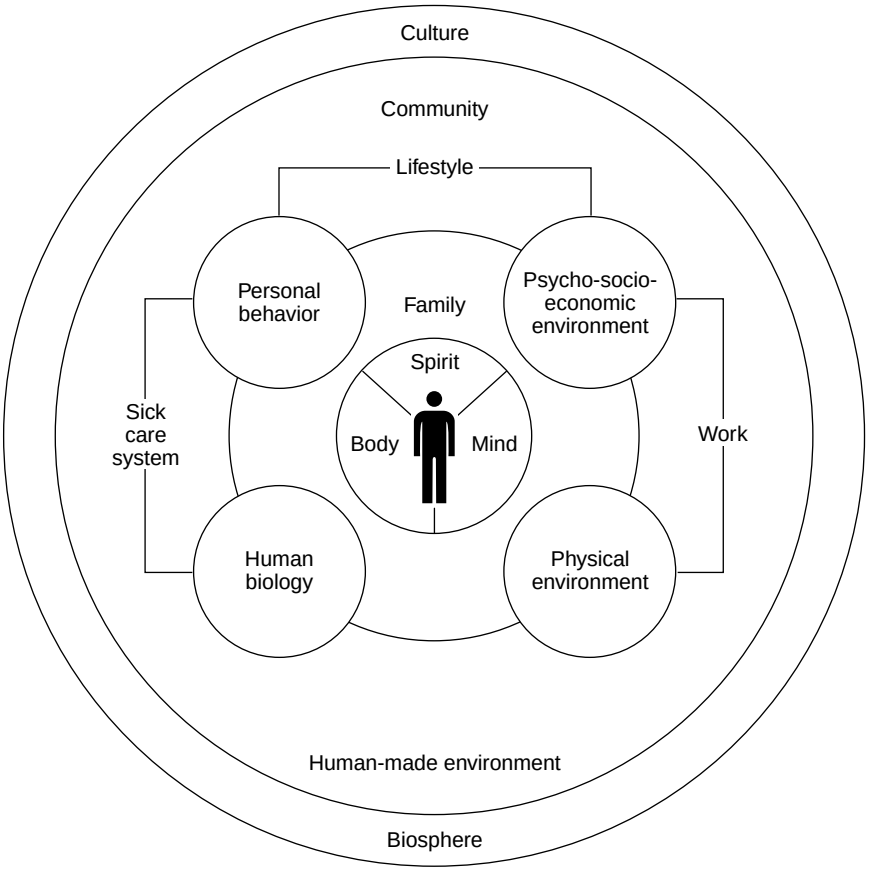

Figure 1 The Mandala of health. A model of the human ecosystem

Mandala is the Buddhist word for an intricate circular design used as a focus for meditation. It has also been defined as a circular symbol of the universe: it is in this latter sense that the term is used; the Mandala is a circular symbol of the universe of health. At the center of the Mandala, the focus for our concern, is the individual human being. That individual's health is a function of their body/mind/spirit integration and well-being, the central concept of holistic medicine and wellness.

That individual is shown as existing within a family. For most of us, for most of our lives and in particular in those important but vulnerable parts of our lives encompassed by infancy, childhood, adolescence, parenthood and old age, the family is our most immediate social environment, just as our home is our most immediate physical environment. The family constitutes one of the great mediating structures of our society: it buffers and protects the individual members from the impacts of community and society; it establishes our values, attitudes, standards and behaviors; it supports us and protects us. (Of course, it must be admitted, families can also have a negative effect, causing stress, even mental and physical damage, the latter through violence.)

The individual and his/her family are in turn affected by four key factors – human biology, personal behavior, psycho-socio-economic environment and physical environment. These four are in fact variants of three of the four Lalonde health fields, namely lifestyle, environment and human biology.

- *Human biology* affects personal and family health through such things as the genetic transmittal of mutations and inborn errors of metabolism, through physiological and biochemical functioning, the competence of the immune system (and the links between the psyche and the immune system), and through the aging process, to name but a few.
- *Personal behavior* is obviously a determinant of health, although constrained and modified by many other factors. The behaviors we are concerned with can be loosely grouped into health promotive or protective behaviors such as proper eating habits, taking regular exercise, managing stress effectively, using seatbelts and crash helmets, and using preventive and other health care services appropriately; and health risk behaviors which include smoking, drug and alcohol abuse, driving dangerously or while drunk and so on.
- The term *psycho-socio-economic environment* addresses two related areas of great importance. The first is concerned with our psychosocial environment, including pressure from our peers at school, at work and in other situations, the influence of media and advertising and related factors. By socioeconomic environment, we are referring primarily to the influence of social status, class or income, which have profound influences on people's knowledge, skills, resources and opportunities, and on their living and working conditions, as they attempt to lead healthy lives.
- By *physical environment*, in this particular section of the model, we are referring primarily to the immediate indoor environment of home, school, workplace and other indoor settings where most people, especially in industrialized countries, spend so much of their lives. The design of our buildings, their air quality and the hazards (physical, chemical, mechanical and biological) they contain have important effects upon health.

The next level of the Mandala shows three particular connections between these four factors that are of importance to health. The first of these is called the sick care system. This term is used specifically to indicate that what we usually refer to as the health care system is in reality primarily concerned with sickness rather than with health. This is not to belittle the system, or those who work within it, far from it. The role they perform is indeed a vital one and when we become sick we would all like to have an effective and efficient sick care system to care for us. But those working within that system have primarily been trained in the recognition, diagnosis and treatment of disease, and are often less knowledgeable about the maintenance and promotion of health, skills in which they have not usually been trained.

A second important point is that the sick care system is primarily concerned with human biology and personal behavior (in the sense of physical and mental health) and is not very involved with – and often not very concerned about – the other elements of the Mandala. This is why the sick care system is only a relatively minor determinant of health.

Work forms a very important function in our lives, at least in the Western industrialized culture. Not only is the physical environment of the workplace frequently a hazard to health, so too is the mental and social environment of the workplace, which can be a source of stress, alienation, boredom or frustration. On the other hand, work is an important part of our social identity, can often be an important source of meaning and purpose in our lives and provides one of our key social networks.

The term *lifestyle* is here shown to be the consequence of the interaction of personal behavior with the psycho-socio-economic environment, within the context of community and culture. Lifestyle is a complex phenomenon, not simply a matter of personal behavior and personal choice. As an example, imagine trying to lead the lifestyle of a Buddhist forest monk in downtown Toronto in the middle of winter. While such a lifestyle choice is clearly possible, it is also clearly a difficult one to make and to sustain, given our social and cultural environment and our physical environment. On the other hand, it would clearly be

quite easy to choose such a life in a country like Burma. The point of this example is not to deny the existence of free choice, merely to indicate that choice is constrained and limited by broader social, cultural and environmental factors.

All of these factors function within a third level of the Mandala, namely that of the community and the human-made environment. As already indicated, the community has its own set of values and standards, and its own social and cultural characteristics that influence our health. Human services are organized at the community level in the areas of health, education, social services, recreation and other areas by the public, private/for-profit and voluntary/non-profit sectors. In addition, the community has a broad range of organizations, groups and networks which provide what McKnight (1995) has termed *associational life* or what Putnam (1993), among others, refers to as *social capital* – churches, self-help networks, neighborhood associations, service clubs, unions, school and home associations, and so on. They play a vital role in our health by providing the social networks and social support necessary for healthy social functioning.

The human-made environment encompasses the built environment of neighborhoods and urban settlements. But the notion of the human-made environment also encompasses the human-modified environment – massive agricultural, energy, transportation and other systems which have left virtually no segment of the world untouched or unmodified by human hands. All of these systems, and all of this human modification have enormous implications for health.

The final level of the Mandala encompasses culture and the biosphere. These are the overarching contexts within which we lead our lives. Culture refers to cultural norms and values that underlie how we think about health, how we believe health and illness are determined and what steps we take as a society and as individuals to improve health or treat illness. In countries as culturally diverse as Canada and the United States now are, there are many different cultural norms and values at work, from those of the aboriginal people to the cultural beliefs of recent immigrants from Asia, Africa, Latin America and the Caribbean. Nonetheless, the basic cultural values and beliefs are rooted in the Judaeo–Christian heritage, Western ideologies of liberty and democracy, scientific rationality, technological civilization and domination of nature. These all greatly affect our understandings of and approach to health.

The biosphere is the ultimate determinant of health. The biosphere is the term used to describe that thin shell of the planet that contains plant and animal life. It is this thin skein of the web of life that keeps us alive, providing our life support systems and a range of other eco-services. The rediscovery in recent years of the ecological principles that our ancestors and aboriginal people understood so well has led us to accept that we are a part of and within nature, rather than separate from and dominant over nature. Only through such an understanding will we come to accept, as the 1990 World Health Day slogan puts it, that we really should think of our planet, our health'.

The Mandala of Health has proved to be a useful conceptual model for understanding health, and an important teaching tool. As with all such models, it will no doubt be superseded with time. But for the moment, it is a useful representation of our modern theory of health.

Thoreau, Henry David

(1817- 1862)

Henry David Thoreau, US writer, poet and philosopher, is considered to be the godfather of American environmentalism, due to his authorship of *Walden*, his ascetic lifestyle as illuminated by *Walden*, and his later contributions to natural history.

Thoreau was born in Concord, MA, in 1817, and was influenced early on by a powerful intellectual and spiritual movement in New England called the transcendentalists, of which the most famous figure was Ralph Waldo Emerson (1803–1882). This movement sought to apply the teachings of German Romanticism in an American context. These teachings sought spiritual understanding in generating powerful connections between the newly emerging individual in modern society, and the unspoiled natural world. Thoreau, and others more loosely associated with the transcendentalists, were open to many influences, including the earliest translations in the west of Buddhist and Hindu writings.

Upon graduation from Harvard in 1837, Thoreau began a haphazard career as a writer, land surveyor, worker in his father's pencil factory, and occasional lecturer. His first book, *A Week on the Concord and Merrimack Rivers* (1849) which described a boat journey Thoreau and his brother took (embellished with natural history, stories, and embedded short essays on a variety of subjects), was a complete failure. Thoreau continued to publish natural history essays and travel essays in American magazines throughout the rest of his life, of which the most famous are probably *Ktaadn and the Maine Woods* (1848), *Cape Cod* (1855) – both later turned into books – and *Walking* (1862). His essay *Civil Disobedience* (1849), written in opposition to the war with Mexico, has been widely influential in setting out the citizen's responsibilities in the face of what can be considered immoral acts by one's own government.

His most famous book *Walden* is a composite diary of the years 1845–1847, during which Thoreau chose, as an experiment, to build a hut and live a marginal life beside Walden Pond, approximately 3 km away from his native Concord. The book deliberately challenges many of the working assumptions of the culture of his time, particularly the obsessions with work, property, and getting on. In chapters such as *Economy*, Thoreau parodies these obsessions, and simultaneously promotes a range of other values: voluntary simplicity, humility, and simply watching the world pass by. *Walden* weaves together in beautiful, clear prose, these social and political themes, together with details of the natural history of the pond and its environs. Since its publication in 1854, *Walden* has become a touchstone of the environmental movement: evidence of this can be seen in the very public, and ultimately successful struggle in the 1990s to protect Walden Pond from encroaching development.

In recent years, more attention has been paid to Thoreau's *Journal*, his daily record of natural history that he kept intermittently from 1838, and then rigorously from the mid-1840s on. There are indications that he intended turning this into a larger natural science book, but died before this could be carried out. Scholars currently see this later more intense focus on the details of natural processes as symptomatic of a continuing dynamic tension between the demands of literary art and the rigors of science in Thoreau's late work.

The Succession of Forest Trees (1859) is generally regarded as Thoreau's main contribution to natural history, in which he sets out the first scheme of ecological succession. In this period, he also became widely known for his support for anti-slavery, and his lectures, including *The Last Days of*

John Brown (1860), brought him to the attention of a wider audience. Thoreau died of tuberculosis in 1862. The elegy at his funeral by his mentor Ralph Waldo Emerson was also influential in bringing Thoreau to public attention. By the turn of the 20th century he was firmly in the pantheon of great American writers; and his well-wrought phrases, such as In Wildness is the Preservation of the World have entered the environmentalist armory.

Three Mile Island

Three Mile Island (TMI), a commercial nuclear reactor 16 km southeast of Harrisburg, PA, was the site of the most serious reactor accident in North America.

On March 28, 1979, at approximately 4 a.m., Unit 2 at TMI moved to an automated shutdown. The reactor technicians on duty inadvertently uncovered the core of the reactor creating conditions that could lead to a meltdown. A valve in the reactor, forced open by the sudden and violent shutdown, had stuck open, allowing cooling water to pour from the reactor. The auxiliary pumps came on, as programmed to ensure adequate water to cover the core. Unaware of the stuck valve, the technician on duty, Craig Faust, believed the core to be receiving too much water and shut off the pumps. Operators also opened another drain line to remove what was interpreted as dangerously high water levels. Remaining water turned to steam, the uranium rods overheated and ruptured. Radioactive water was discharged outside the reactor, and radioactive gases, were vented.

Not until the morning of March 30, 1979 did the governor suggest that pregnant women and families with small children might want to leave the area. Over the weekend, an estimated 140 000 people evacuated.

Estimates by the Nuclear Regulatory Commission (NRC) study group were that TMI had come within thirty to sixty minutes of meltdown. Previous NRC worst case analyses had estimated that a major nuclear reactor meltdown could create an area of ••• disaster that might be equal to the State of Pennsylvania. Coincidentally, as TMI occurred, a major Hollywood movie about a nuclear plant accident, *The China Syndrome*, was playing. A scientist character in the film quoted the NRC area the size of Pennsylvania destruction estimate.

Estimates of deaths due to the accident vary from several hundred excess cancers to several thousand. There has not been a single new nuclear reactor built in the United States or Canada since the TMI accident.

ELIZABETH MAY *Canada*

Torrey Canyon

Torrey Canyon, an oil tanker which ran aground in the English Channel in 1967 was the world's first major oil spill. Torrey Canyon became a spark for the growing environmental movement in the late 1960s. It remains one of the most devastating oil spills in history.

The Torrey Canyon spilled 31 million gallons (117 million liters) of oil into the English Channel, resulting in the death of between 40 000 and 100 000 seabirds. Later well-known oil spills released a fraction of the cargo of the Torrey Canyon. The Amoco Cadiz spill in March 1978 off the coast of Brittany coated an estimated 100 km of coastline, but spilled far less oil, 1.5 million barrels of crude oil. In July 1983, the Alrenus wrecked on the coast of Louisiana spilling 2.27 million gallons (eight million liters) of oil. The Exxon Valdez spill (*see* Exxon Valdez Oil Spill, Volume 5) lost about one-fifth of its cargo, 11.2 million gallons (42 million liters) with devastating environmental effects.

UNU (United Nations University)

The UNU is the principal academic research institution of the United Nations (UN). It is an organ of the UN similar to the UN Development Programme or the UN International Children's Emergency Fund, and reports to the General Assembly and the UN Economic and Social Council. Its role is to focus intellectual resources from many nations on world problems of interest to the UN system. It organized the first conference on the Human Dynamics of Global Environmental Change in 1988, pioneered intergenerational environmental law, led the Mountain Agenda at the UN Conference on Environment and Development, and other environmental efforts.

This post-graduate research and training institution does not have professors or students. Instead, the UNU is a worldwide network of networks of scholars whose purpose is to develop options for the solution of problems that require truly international collaboration. It is the UN's think tank and has published hundreds of books, facilitated thousands of research fellows, and conducted hundreds of conferences and workshops to further knowledge of human security and development. See http://unu.edu.

UNU has scholars instead of countries on its governing council and funds about half of its research though an endowment. These approaches helps ensure academic autonomy.

Although headquartered in Tokyo since it opened in 1975, UNU has research and training centers and programs around the world with their own governing councils and funds in areas such as: development economics in Finland, new technologies in the Netherlands, software technology in Macau, advanced studies in Japan, natural resources in Ghana, biotechnology in Venezuela, leadership in Jordan, regional governance in Belgium, environmental health in Canada, food and nutrition in the US, fisheries in Iceland, and conflict resolution in the UK.

UNU headquarters has two primary programs: (1) peace and governance; and (2) environment and sustainable development. The second of these focuses on human–environment dynamics including environmental governance, policy, and advanced training especially in developing countries. Its research contributes to the work of the UN system and seeks partnerships with others involved in sustainable development research and training. It publishes the journal *Global Environmental Governance* and has established the Global Environment Information Center to reach out to the larger community on environmental issues.

For a description of one of the UNU programs, *see* Scenarios, Volume 5.

Virtual Environments

Gale Moore
University of Toronto, Toronto, Canada

The term virtual environment is used very broadly to describe a variety of computer-generated spaces. Virtual environments have been made possible by developments in information and communication technologies (ICTs) and their convergence with a broad range of electronic media, Internet and virtual reality (VR) technologies, both synchronous (same time) and asynchronous (different time). These technologies constitute what Kitchin (1998) has called cyberspatial technologies, referring to the term Cyberspace, rst used by William Gibson in his science ction novel, Neuromancer (1984) to describe electronic space. We experience these environments as real, when they are in fact, representations of reality that do not exist in the material world, except in the technical components that comprise them. This broad de nition draws attention to the variety and diversity of digital media that characterize these environments, and provides a continuum along which readers outside this eld of research can move if they wish to explore further.

We live in an era characterized by the intensification of the symbolic: information and knowledge are the resources of the 21st century and the source of economic growth and wealth creation. Environmentalists understand the power of symbols, and the meanings that come with new forms of representation. Consider the profound shift in human thinking brought about by globalization, a shift symbolized by the image of the earth as seen from space. How has this structured the way we think about the natural world? Environmentalists have also engaged in the exploration of a complex boundary – the interface between nature and culture. What insights and perspectives might they bring to the exploration of the boundary between the physical and virtual worlds brought on by our engagement in virtual environments?

Virtual environments have been made possible by developments over the past 40 years in ICTs, interactive computer graphics, and VR. These environments vary in their representational richness, i.e., in the nature of the media, and the specific forms of symbolic representation that comprise them, e.g., text, graphics, audio, video, etc. But it is the ways in which this class of technologies is capable of extending our senses and our intelligence that has the potential to change not only the way we work, live and learn, but also the way in which we think. As Postman (1992), reminds us:

> New technologies alter the structure of our interests: the things we think about. They alter the character of our symbols: the things we think with. And they alter the nature of community: the arena in which thoughts develop.

The experiences of users in these emerging representational worlds, and the significance of these environments in both shaping and being shaped by these experiences, is a topic of considerable research and debate – and one that demands an interdisciplinary response.

Today's virtual environments are the current end product of a long movement across the spectrum of technologies that have changed our relation to time and space – the train, for example, in the 19th century, and in the 20th century – the telephone. However, as we move toward the virtual reality (VR) end of the continuum, they are also more than this.

The familiar experience of the telephone may be used to illustrate the concept of virtuality. Today, the telephone is so embedded in the activities of everyday life that we forget that the voice we hear at the other end of the line – a voice instantly recognizable if that of a friend or family member – is not actually a voice, but a representation of that voice. With today's digital packet switching networks, the voice is not only digitized, or broken down into a string of ones and zeros, but the packets created travel by various routes to their final destinations. The receiver perceives a continuous conversation and a familiar voice. In reality, this is simply a representation of the voice, and if the technology breaks

down, the voice will neither be recognized nor understood. We do not stop to think of the telephone as a type of virtual environment, but the communication space or environment supported by the technology of telephony is, in essence, virtual. The immersion in a virtual three-dimensional (3D) world is only an extension along this continuum.

At the VR end of the human machine continuum, we are dealing with technologies that are more postmodern than modernist in their application, i.e., a world of symbols and representation in which multiple realities can be simulated. As our senses are extended, the boundaries between the real and virtual world are blurred. Increasingly, it will be difficult to discern what is real when increasingly large parts of our reality are, in fact, virtual or more accurately, a virtuality. Rheingold (1992) suggests these environments are not real in the sense that we understand the physical world, nor are they virtual, the opposite of real. The system's virtuality is a *structure of seeming* the conceptual feel of what is created. The physical body recedes; the mind and senses are at the forefront. Identity becomes labile, symbols are real and we immerse and navigate in an electronic world. It is this vision of a disembodied future, a blurring of the boundary between the human with the machine. There is an increasingly symbiotic relationship between the physical and virtual worlds. Virtual environments are like this; this is part of their power and our fascination with them.

TYPES OF VIRTUAL ENVIRONMENTS

The first type of virtual environment *information environments* will be the most familiar. These are primarily text-based, and a number have emerged around the power of computer technology to store large quantities of data. Information environments have helped solve two of the great problems of the human mind: limitations on the amount of information that can be stored, and the problem of retrieval. These environments augment human intelligence by freeing the human mind to carry out activities for which it is uniquely suited pattern recognition, evaluation and contextualization. We navigate through vast data spaces and digital libraries of information, manipulate textual and numeric symbols, and give them representational form that conveys the underlying pattern and relationships uncovered by the human mind. Information management, or more fashionably, knowledge management, are current expressions of the potential of information environments. Initially, these environments could support only one user at a time, but their power multiplied when machines could be networked. A fascinating example is the exponential growth of the World Wide Web, a global collection of hypertext documents that allows users with a browsing program such as Internet Explorer or Netscape Navigator, to access what, in a few years, has begun to approximate an electronic global Alexandrian Library.

Closely related are the *communication environments*; spaces in which people interact, not only with data and its representation, but also with other people what researchers call *human human computer-mediated communication.* Media such as email, listservs, bulletin boards, and chat, make it possible for people across the globe, who are connected to the Internet, to interact in new ways that challenge our understanding of time and space. Many of these are text-based environments, and individual media may be either synchronous, i.e., they require that users be present at the same time, or asynchronous, as is the case with email, where messages can be sent and received at different times.

Chat services, such as Instant Messenger™ recently entered the public domain. In a typical chat environment, the user has a series of icons representing people who are willing to chat. These people may be local or distributed around the world. At a glance they can observe who in the group are currently online (the icon changes color) and, hence, are accessible. Even if a chat is not initiated, this awareness of friends and colleagues affords an opportunity for interaction that is, at a minimum, comparable to awareness of the presence or absence of others in a physical office environment.

While the potential for interaction may appear limited in these environments, the increased availability of computers and access to the Internet since the mid 1990s has, in fact, resulted in an explosion of online communities groups of people sharing a common interest who meet regularly using a variety of mediated communication tools and environments. These communities and their members have been an important subject in recent years, drawing attention to the potential of even these limited environments to support rich and complex forms of social interaction.

Collaborative environments or *collaborative virtual environments* (*CVEs*) are applications that allow multiple users to meet and to communicate, and depending on the representation richness of the environment, to collaborate and to share a variety of documents and artifacts.

The first examples of this type of environment are MUDs (*multiple user domains*). There are a number of other environments such as MOOs (*multiple object-oriented*), or MUSEs (*multiple user social environments*), which, while differing in technical functionality, provide a similar opportunity for social interaction. Initially, MUDs were text-based, and used a variety of textual conventions such as *emoticons* (e.g., ;-) is a smile) to enrich their real-time conversations, and to compensate, in part, for the lack of gesture, eye contact, voice tone and inflection normally available in face-to-face communication. A rich visual vocabulary of emoticons now exists. MUDs have traditionally been developed within the context of specific groups of users, and the ways in which these spaces are socially

constructed is of particular interest. Research has found that these virtual *spaces* often became *places*, i.e., settings with their own culture and behavioral norms. While these spaces do not realistically represent a specific place in the material world, they do represent a type of place, for example, a classroom or a cafe. Behavioral norms and community standards emerge out of the interactions of the members of the group involved in the CVEs, and deviant behaviors are punished.

The power of these environments is further increased when a variety of media and forms of representation are supported. Today, there are a number of commercial CVEs available, which can be accessed using a standard Web browser. Examples include: Placeware • www.placeware.com• , Teamwave • www.teamwave.com• or eRoom • www.eroom.com• . The majority support standard communication activities, both synchronous and asynchronous, such as email, *document sharing*, and chat. The more sophisticated environments also provide tools to support interaction and negotiation – voting and document versioning, for example. A number offer both public and private spaces and storage areas for files and work in progress. Access to, and use of these environments no longer require the acquisition of a new set of skills. However, while the potential of these environments for community building, as well as supporting collaboration in the workplace, is real, the sociology of these spaces is still not well understood, and they are often underutilized. More recently, CVEs have appeared that incorporate a visual component, more specifically, a 2–3D visual representation of the space in which participants can interact with each other and with objects.

Before moving to these VR environments, mention should be made of another type of virtual environment: media space. *Media spaces* are audio–video computer-mediated communication environments. Unlike the CVEs discussed above, media spaces connect two or more sites in real time and like the telephone, or a videoconference, allow users to see the physical reality at the remote end and to hear what is taking place. In the Ontario Telepresence Project (Moore, 1997), a variety of types of spaces, for example, offices, meeting rooms, etc., were connected across two geographically separate locations. In the media space, it was possible to meet colleagues in their offices even though they were not in the same city. It was also possible to check the parking lot at the remote location to see if a colleague's car or bicycle was there, or to wander the corridors at the remote location, glancing around looking for someone. Multiple monitors were used at each end to keep the person space and the task space separate. While information on computer screens was being shared, individuals could both see and talk with each other as they might if co-located. Pauses and silences could be interpreted, as could interruptions at either end. Media spaces were designed in the context of real world practices and one of the challenges of this research was to support *presence* – i.e., to represent over distance the richness and experience of face-to-face interaction such as gesture, tone, and gaze awareness.

From the 1960s on, advances were being made in distinct areas such as interactive computer graphics and VR, but these advances would not converge until the 1990s. Rheingold (1992, p 46) traces VR's roots back to the 1930s and early experiments with immersion, such as Cinerama, but he argues that VR progressed slowly in the 1970s as it waited for enabling technologies to mature. While media space researchers had been concerned about one type of presence, researchers in robotics had a different view of telepresence, namely, how to support human intelligence when it is necessary to carry out activities remotely; e.g., to defuse a bomb or carry out a surgical procedure. Some of these experiments relied on head-mounted displays, or data gloves, and other research came from the entertainment and games environment. By the 1990s, however, these areas were converging to create a powerful new reality – a reality in which a number of human senses were extended or augmented. It is at this end of the continuum that the boundary between the material world and virtual world is softening, shifting, and blurring. In the future, the virtual environments will be as familiar or perhaps more familiar than the physical environments we experience today.

The most accessible of the newer CVEs are the *virtual reality environments*, which use modeling languages such as virtual reality modeling language (VRML), and allow for participation using a web browser and the Internet.

Virtual worlds are a popular form of these environments. These surreal multi-user 2–3D worlds generally do not represent actual places in the world, but are imaginary landscapes that provide spaces or opportunity for human interaction. These are real-time or synchronous environments in which people are represented by graphical icons known as *avatars*. There is a strange out-of-body sensation as you navigate through these worlds, sometimes flying, meeting and interacting with others. You may find yourself in conversation with familiar characters such as Alice in Wonderland or Wanda the Fish; two popular avatars that people select to represent themselves. These worlds are, in general, themed, and provide fascinating insights into the nature of identity in a postmodern culture. The coherence of a single physically embodied identity slips away – if one desires, and multiple persona are not unusual. The technology makes it possible, but the motivation of the participants and the nature of the communities that evolve continue to raise questions about the nature of human experience. A number of these environments can be visited. The Contact Consortium web site maintains a useful set of links • www.ccon.org• .

Other CVEs are grounded in real-world practices, but most continue to be based on spatial metaphors. While the environments may not be realistic in terms of a specific

location in the physical world, many, like MUDs, are realistic in terms of the type of place they represent. For example, you recognize that you are in an office or a store and individuals behave in ways that are coherent with the repertoire of socially appropriate behaviors understood in the physical world. Extensive social and behavioral research is increasingly part of the development of these environments, underlining the desire to understand how these shared visualizations and environments can be used to support new forms of collaboration among people.

John Robinson and his colleagues at the Sustainability Research Institute at the University of British Columbia • www.sdri.ubc.ca• have created a space of particular interest to environmentalists. They have created 2D models (accessible from a Web browser) to increase the understanding of sustainability issues. Through the development of thought-provoking technology-aided experiences, which solicit user input and provide a visual representation of outcomes based on this input, users deepen their understanding of highly complex issues.

The most technically complex of the virtual environments are in the realm of VR. As Mitchell (1995) articulates: virtual reality technologies partially or totally immerse users in an interactive visual, artificial, computer-generated environment; instead of the users being spectators of a static screen, they are participants in an environment that responds . The key differentiator of these environments is that the users are immersed and interact with the environment in realistic ways. No longer the stuff of science fiction, these environments are at the interface between the real and the virtual world. Surgeons, for example, can now rehearse a difficult operation using a 3D representation of an actual patient. Airplane manufacturers can design and engineer an entire aircraft in a 3D environment. There is no physical scale model; the first plane that is built, flies. The design team may be distributed across the globe and work together in real time. The range of activities that VR supports, and the nature of the collaborations that are possible, suggest it will be applicable to many of the activities and interactions of daily life. How will our societies change as material reality and social interactions are augmented and mediated in the ways VR makes possible?

The cyberspatial technologies that comprise virtual environments extend and augment human intelligence and are changing not only what we think about, but also what we think with. If we directly apply this theme of virtual environments to the prospects for global environmental change, one pervasive notion is that as the natural or social environment deteriorates, people will increasingly move into virtual environments. The dystopians give us images of a retreat from public space into new worlds supported by technology. The utopians see the potential for human good. However, like the technologies that have gone before and those that are ahead, virtual environments are neither good nor bad, nor are they neutral. They emerge out of a specific socio-historical context and out of a specific set of social relations. They are shaping and being shaped by those who design, build and use them. Cyberspace may be a consensual hallucination, but when the electricity goes out – the illusion cannot be sustained. We are forever embodied – it's the human condition, and in the end it is nature that holds sway.

Waldsterben

Waldsterben is a term widely used in Europe to denote forest decline in the late 1970s and early 1980s when it became a public issue. In mountainous regions particularly in the vicinity of the Poland, Germany and Slovakia triangle, thousands of hectares of forest died in a few years. The causes of waldsterben are complex, and may include direct damage to needles and leaves from industrial sulfur emissions, long-range acidic deposition, drought and mobilization of heavy metals in acidifying soils. Waldsterben is very photogenic and therefore it caught the attention of Green Parties, and other environmental non-governmental organizations. It is interesting to note, however, that the overall trend in forest growth in Europe over recent decades has been increased productivity.

WCC (World Council of Churches)

The WCC is a fellowship of about 350 denominations worldwide with a combined membership of approximately 400 million persons. The participating churches in the WCC cooperate on programs of world development and relief, theological reflection and education, and advocacy on issues of justice, peace and creation.

Environmental concerns have been a dimension of the WCC's activity for over 30 years. Since 1988, climate change has been the main focus for the environmental work. The WCC Climate Change Programme includes preparation of resources on theological and ethical dimensions of the problem, support for environmental activities of churches in the South, and coordination of advocacy at the international level and among industrialized countries whose societies are responsible for the majority of emissions leading to climate change.

For further information, contact The World Council of Churches (Justice, Peace and Creation Cluster), 150 route de Ferney, PO Box 2100, 1211 Geneva 2, Switzerland. Tel.: • 41-22-791-6111; Fax: • 41-22-791-0361, Email: mpt@wcc-coe.org, Web site: www.wcc-coe.org.
