The lack of thresholds for air pollutant impacts from the observational epidemiological studies does not imply that individuals do not have a threshold below which they are not affected. There is a broad distribution of people with pre-existing conditions within any population and each could potentially have his/her own threshold. Furthermore, this threshold could vary in time depending on a person's current health. The present observational studies do not provide information on specific individuals so the entire range of ambient concentrations is associated with some health response within the population.

Even if a threshold can be identified, it would have been derived from currently available data and methods, which generally have limitations. New information could reveal that the most relevant threshold is different than the currently accepted value. For example, there is presently very little data on the chronic or long-term effects of air pollutant exposure. Consequently, the CRFs and subsequently identified standards are based on impacts of acute exposures. Future data from chronic effect studies could lead to different CRFs and threshold estimates that may be more relevant for minimizing or eliminating the effect on the population. Thus, the process of standard setting is an ongoing process of re-evaluation as knowledge increases. Epidemiological studies play an important role in this process.

Without evidence of a threshold, setting a defensible air quality standard is difficult. Risk analysis/management is one option to be considered, but it is necessary to define an acceptable level of risk to public health. Should the most susceptible members of the population be protected or should the average person be of most concern? Should the cost of emission controls be an issue? Can such costs be reliably compared to the cost to society arising from the burden on public health? Should a margin of safety be considered? There are no simple answers to such questions. However, to be able to undertake a quantitative, scientifically defensible analysis, a CRF is required for each health endpoint to be considered (e.g., mortality, hospital admissions, incidence of bronchitis).

The two main approaches for deriving a CRF are to:

1. Quantitatively combine the results from the most robust epidemiological studies to establish a relatively broad-based CRF (referred to as a *meta-analysis*);
2. Rely on the most relevant study for the area/country of interest.

The meta-analysis approach is useful because published data from multiple studies can be considered so there is typically a greater degree of confidence in the derived CRF. In addition, this CRF should be more generally applicable for a broad range of geographic areas, even those not represented by the original epidemiological studies. The second approach directs significant attention at one study and thus, it is important to critically review its strengths and weaknesses before applying the results.

In many epidemiological studies, particularly for rare events like mortality, the air pollutant effect is expressed as a relative risk per given change in the ambient concentration. Relative risk values are useful because they can be translated into a percentage change in the incidence of a health effect for a baseline population. To apply risk estimates, it is helpful to standardize them to a unit change in concentration yielding a CRF. The final step in applying the CRF is to obtain the baseline rate ($\overline{Rate}_{outcome_i}$) for the corresponding health outcome, i, (e.g., cardio-respiratory mortality) expressed as number of occurrences per given number of people (e.g., per million population).

CONSIDERING THE OPTIONS FOR A PM STANDARD: A CASE-STUDY BASED UPON A RECENT CANADIAN EXERCISE

In Canada, a group of air quality and health experts from governmental agencies at the federal and provincial/territorial levels, with support from outside experts as needed, provide guidance to air quality managers for development of ambient standards and management strategies. Involvement from various levels of government and geographic regions ensures that a broad range of perspectives is considered. In addition, this group consults with stakeholders, such as environmental and health organizations and industry. This process was followed to provide guidance for setting national ambient standards for fine PM.

Three approaches for developing health-based recommendations for the standard were considered:

1. Base the standard on the *lowest observable adverse effect level* (LOAEL), which is the lowest concentration at which one is confident that there are adverse health effects;
2. Base the standard on the LOAEL incorporating a margin of safety based on uncertainty factors;
3. Base the standard on an analysis of the health benefits of achieving various arbitrarily defined $PM_{2.5}$ concentration levels.

These approaches were the only justifiable options given the lack of evidence of a health effect threshold or a no-observable adverse effect level (NOAEL: the highest concentration at which one is confident there are no adverse health effects), for PM_{10} and $PM_{2.5}$. Following any of these approaches necessitated identification of CRFs to be able to identify the LOAEL and/or to estimate health benefits.

Daily mortality rate and hospital admissions were selected as the health endpoints to be considered in the standard setting exercise. Mortality was selected due to the large number of studies reporting consistent and similar effects. Hospital admission rates were considered because several Canadian studies used this endpoint and because hospitalization studies capture a larger segment of the affected population compared to mortality studies. Hospital data in Canada are extensive and reliable due to the nationalized health care system. In general, the data for these two endpoints should be much more reliable than subjective measures of $PM_{2\cdot5}$ impact such as absenteeism, restricted activity and prevalence of respiratory symptoms (e.g., asthma), which are often obtained through surveys.

The CRF for mortality was determined after review of many studies, including those involving PM_{10} or other particle-related measures such as particulate sulfate concentration and British smoke shade or black smoke (BS). Due to the availability of concentration measurements, there were more studies involving PM_{10}. Thus, a meta-analysis approach was used to determine the CRF. Though $PM_{2\cdot5}$ is suspected to be a stronger indicator for human health effects, there were a limited number of studies. Therefore, the $PM_{2\cdot5}$ CRF for mortality came from one publication summarizing/combining the associations (mortality vs. $PM_{2\cdot5}$) among six US cities (Schwartz *et al.*, 1996). Since this study included multiple cities, it was expected to provide a representative CRF, applicable to Canadian populations. The reliability of this study was demonstrated by its PM_{10} results, which were consistent with a wide range of other studies.

The CRF for hospital admissions was derived from one Canadian study (Burnett *et al.*, 1995), which involved a large population residing in Ontario. Like the selected mortality study, the PM_{10} and $PM_{2\cdot5}$ relationships derived from this study were consistent with the results found in other investigations for other locations. The values of the CRFs used for the Canadian exercise are given in Table 2.

As discussed above, a NOAEL could not be determined because the epidemiological studies found an increasing effect throughout the entire range of PM concentrations. However, from the studies providing the CRFs it was possible to identify a concentration below which data limitations lead to less statistical confidence in the health effect relationship. This involved examining the relationship at the lower end of the concentration distribution by determining average mortality or hospitalization rates (suitably adjusted for temporal and weather factors) for selected ranges of PM concentrations such that these average rates increased with increasing concentration. Statistical tests were then used to determine the concentration at which the rates were different from the rates associated with the next lower concentration range. The lowest concentration at which a statistically significant increase in admission rate was observed was denoted as the LOAEL. Thus, the LOAEL is the level above which there are demonstrated effects on human health. It is scientifically based and provides a basis for establishing goals for long-term air quality management. This *statistical threshold* does not represent a threshold in the classic sense and the shape of the relationship could be linear below the LOAEL, but the benefits of achieving air concentrations below that level can not be calculated with confidence.

Table 2 Concentration-response functions (% change) associated with a $1\,\mu g\,m^{-3}$ change in 24 h average $PM_{2\cdot5}$ concentration

Health endpoint	CRF (95% confidence interval)
Mortality	0.14 (0.18, 0.10)
Respiratory hospital admissions	0.074 (0.099, 0.049)
Cardiac hospital admissions	0.07 (0.10, 0.036)

Figures 2(a,b) provide an example of how the LOAEL was identified from the Canadian hospitalization data (Burnett *et al.*, 1995). First all PM measurements were grouped into concentration ranges. In Figure 2(a), which shows 24 h average $PM_{2\cdot5}$ calculated from sulfate, four groupings were found to best represent the relationship because of the clear increases in respiratory and cardiac hospitalizations from group to group. The difference in the hospitalization rate between each group is shown in Figure 2(b). The rates within the second group, which has a 24 h mean $PM_{2\cdot5}$ of $15\,\mu g\,m^{-3}$, are significantly different from the first group because the confidence interval (± 2 standard errors) does not include zero. Sub-dividing the lowest concentration group further and comparing hospitalization rates amongst these groups showed that there were no statistically significant changes in rates at these lower concentrations. Thus, the average concentration of the second group was taken as the LOAEL (i.e., $15\,\mu g\,m^{-3}$). Similar analyses involving the concentration-mortality functions derived from the six US cities, yielded a similar value for the LOAEL. The first standard setting approach listed above was therefore based upon a LOAEL of $15\,\mu g\,m^{-3}$ (24 h average). The second approach, which will not be discussed further, was also based upon this number, but with adjustments allowing for a margin of safety.

The third approach for development of standards involved examining the health benefits, or avoided impacts, of achieving various 24 h $PM_{2\cdot5}$ concentration targets. The steps involved in this process are outlined in Figure 3. First, target levels are identified and the current/recent ambient measurements in the region of interest (e.g., Canada) are compared to this value. New distributions of ambient concentrations are predicted using various rollback algorithms until all or a given percentage of the measurements are below the proposed target (Figure 3a). In Figure 3(a), the $PM_{2\cdot5}$ concentration on all days with levels above the

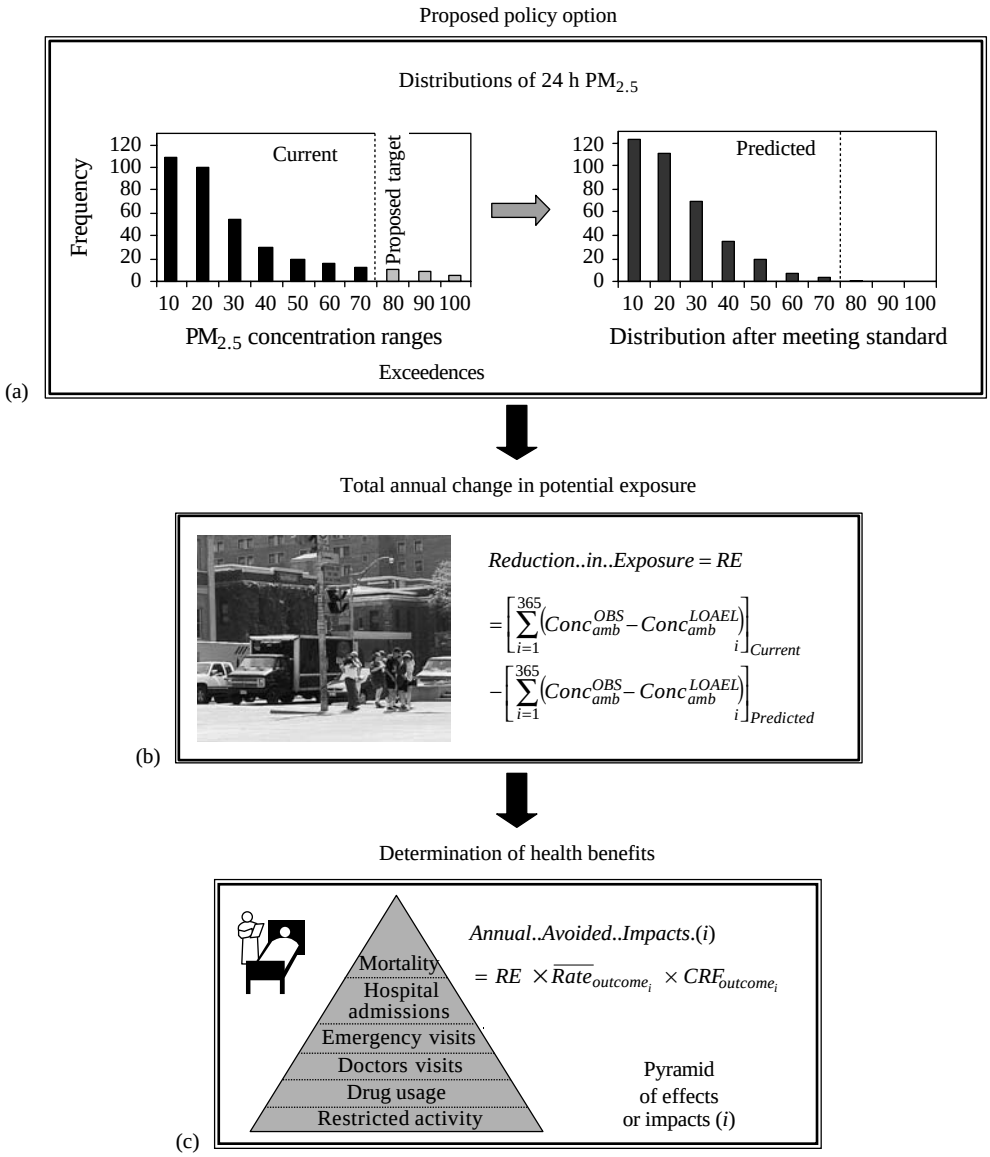

Figure 3 Steps involved in estimating the health benefits of a proposed air quality standard for $PM_{2\cdot5}$. (a) The current observed annual frequency distribution in 24 h concentrations ($\mu g\,m^{-3}$) is modified in a realistic fashion so that concentrations remain below the proposed standard (predicted distribution). (b) The total reduction in exposure (RE) over an annual time period is calculated by summing all concentrations above the LOAEL from the current and predicted $PM_{2\cdot5}$ distributions. (c) The RE is multiplied by the CRF (percent change in health outcome per 1 $\mu g\,m^{-3}$ change in $PM_{2\cdot5}$) and the baseline rate in the outcome (per a given population size) to estimate the annual health benefit (avoided outcome) for the given population size represented by the baseline rate

estimated background concentration decrease (i.e., not only high days with concentrations above the target levels are affected). All days with concentrations greater than the background concentration are assumed to have an impact on health, thus reducing those concentrations is expected to result in Avoided Impacts (Figure 3c).

Given a linear CRF throughout the concentration range, the total annual reduction in $PM_{2\cdot5}$ exposure can be calculated (Figure 2b) separately and then multiplied by the CRF to determine the Annual Avoided Impacts. By definition, it is not possible to reliably calculate benefits when concentrations are below the LOAEL ($Conc_{amb}^{LOAEL}$). Thus, the reduction in exposure (RE) in Figure 3(b) is calculated relative to the LOAEL (a negative difference is set to zero).

Annual Avoided Outcomes can be calculated for a range of health effects, such as those in the Health Effects Pyramid in Figure 3(c). The Canadian exercise involved mortality and hospitalization using CRFs from Table 2. This could be done for additional outcomes such as emergency department visits if reliable CRFs are available.

SUMMARY

Urban air quality is generally thought of as a local human health issue. However, pollutants emitted and building up in urban areas spread throughout the surrounding environment having impacts beyond the local area, ultimately changing the mix of trace gases and fine particles on a global scale. These changes lead to global environmental change such as climate warming due to increasing carbon dioxide and regional-scale cooling due to the direct and indirect radiative effects of aerosols. Combustion is a key source of both carbon dioxide and aerosols, as well as the main smog pollutants. Therefore, the consequences of policy decisions to minimize climate change and to reduce urban air pollution (or lack of such decisions) are strongly linked.

The key policy tool to address urban air quality is the air quality standard. Setting a standard is a complex and iterative process. Application of epidemiological information can be used to support this process. This scientific input to standard setting is weighed along with socio-economic information, technical issues and politics. For this reason it is very important that decisions regarding urban air quality policies are seen in the context of long-term changes in global climate as well as their effectiveness in avoiding or reducing adverse public health impacts.

Valued Ecosystem Component

The phrase *valued ecosystem component* (VEC) first appeared in the environmental assessment (EA) literature in a Canadian work by Beanlands and Duinker (1983, 1984). It was defined as environmental attributes considered to be important in project decisions (Beanlands and Duinker, 1983). Synonymous is the term *indicator* as used earlier by Holling (1978) who defined indicators as measures of system behavior in terms of meaningful and perceptible attributes. Also equivalent in meaning is the term *environmental performance indicator* as used by Duinker and Baskerville (1986). VECs, like the related concept of *ecosystem values* (Duinker and Doyon, 1999), can refer to physical things (both biotic, such as songbirds or moose, and abiotic, such as water or air), ecological processes (e.g., nutrient ow, carbon sequestration), or ecosystem conditions (e.g., degree of soil compaction, biodiversity). The VEC concept was developed in recognition that ecosystems are comprised of too many components for EAs to be assimilated successfully, considering our poor understanding of most ecosystems, budget constraints and the short timeframes imposed on assessors. Thus, EA practitioners need to set priorities on which few components will garner most or all of their analytical attention. Criteria for setting such priorities should include a balance of social, economic and ecological factors, with input from all affected and interested parties (Beanlands and Duinker, 1983). Some EA practitioners prefer to use the term *valued environmental component* (with the same acronym) in a effort to apply the concept equally to ecological, social and economic elements in a broad interpretation of environment.

Vavroušek, Josef

(1944- 1995)

Josef Vavroušek was a Czech environmentalist, scientist and politician, and founder of the Environment-for-Europe process. As a student in Prague in the early 1960s, Vavroušek was one of leaders of the student opposition movement. After the Soviet occupation of Czechoslovakia in 1968 he became Vice-president of the Czech and Slovak young people's organization S.O.S. in Paris (August–September 1968). He obtained his PhD (equivalent) from the Czech Technical University in Prague in 1975 then worked for 15 years (1975–1990) as a scientist in the field of cybernetics, general systems theory, science of science, and human environment, specializing in macro-ecology of Man and environmental policy. During this period he was a member of the executive body of the Ecological Section of the Biological Society, Czechoslovak

Academy of Sciences (1985–1991), one of the founding members of the first executive body of the Circle of Independent Intelligentsia (1988–1989) and a member of the Club of Rome. He was also one of the founders of the Civic Forum and later of the Civic Movement in Czechoslovakia and a member of their executive bodies.

In 1989 Vavroušek was one of the leaders of the Czechoslovakian Velvet Revolution. In April 1990 he became vice-chairman of the State Commission for Scientific and Technical Development (responsible for the environment), and then in June 1990 he became the first (and last) environment Minister of the Federal Government of Czechoslovakia. It was in this role that Vavroušek proposed and organized the first pan-European conference of environment Ministers. In Vavroušek's own words:

> ••• there are not many fields where effective co-operation in continental or even global scale is so necessary, like in the field of environmental protection and restoration. Not a single group of countries can solve the severe legacy of environmental deterioration and find ways towards a sustainable future alone. Environmental co-operation is thus not only the necessary condition for substantial improvements of our ecological situation but also the most natural first step of our European integration.

The conference was held at Dobříš Castle near Prague in June 1991 and was attended by environment Ministers or deputies from almost all European countries together with representatives from many international bodies and non-governmental organizations. The conference initiated an Environmental Program for Europe and a pan-European environmental reporting process (*see* Dobr s European Environment Assessment Process, Volume 4). Vavroušek's initiative and vision thus set the basic framework of long-term European environmental cooperation which has continued with Ministerial Conferences in Lucerne (April 1993), Sofia (October 1995), Aarhus (June 1998) and Kiev (2003).

As environment Minister he headed the Czechoslovakian delegation to the Rio Summit in 1992, but then political changes and the division of the country brought his ministerial career to a premature end. Returning to science he joined the Institute of Applied Ecology at Charles University and then went on to found and become president of the Society for Sustainable Living (established in October, 1992). Vavroušek's contribution to European environmental cooperation was to bring the interdisciplinary experience and understanding of how human systems and the environment work into mainstream political parlance across the new Europe at the time of its birth and to emphasize the importance of human values and environmental ethics in the search for sustainable ways of living. Vavroušek was killed with his daughter Petra by an avalanche in March 1995 while hiking in the Slovak mountains.

DAVID STANNERS *Denmark*

Villach Conferences

In the 1980s several scientific conferences were held, in the pretty resort town of Villach, Austria. These meetings of experts were organized jointly by the World Meteorological Organization (WMO), the United Nations Environment Programme (UNEP) and the non-governmental International Council for Science (ICSU).

The first was in November 1980 under the framework of the then new World Climate Programme (WCP). Its focus was do we have a problem due to rising atmospheric concentrations of carbon dioxide? The scientists concluded that continued consumption of fossil fuels could increase global mean temperature by 1 °C or more early in the 21st century, and continue thereafter. They anticipated that regional ecosystems, agricultural production and water supply will be materially affected . The main recommendation was that a major interdisciplinary research program should be undertaken urgently, and a five-point research agenda was proposed.

Probably the most important and in uential Villach Conference was that held in October 1985, sponsored by the same three organizations. WMO Publication #661 contains the *Report of the International Conference on the Assessment of the Role of Carbon Dioxide and of Other Greenhouse Gases in Climate Variations and Associated Impacts*. This conference had the benefit of a new report prepared by the International Meteorological Institute (IMI), Stockholm and led by Professor Bert Bolin. Among the key findings were that other greenhouse gases, particularly nitrous oxides, methane, ozone and chloro uorocarbons, were estimated to have added one half again as much temperature change as carbon dioxide (CO_2) alone. In addition, the concentrations of some of these gases were increasing more rapidly than CO_2. The IMI report stated that the expected global mean temperature increase due to a double CO_2 equivalent, expected in the 21st century, is of about the same magnitude as the change of global temperature from the last glacial period to the current interglacial . The potential sea level rise in such a scenario was estimated at 20–165 cm. Likely consequences for agriculture and forestry were emphasized.

The experts from 29 countries at the Villach Conference reviewed and debated the IMI findings and produced their own hard-hitting statement. It said that combining the other greenhouse gases with CO_2 meant that, it is now believed that in the first half of the 21st century, a rise of global mean temperature could occur which is greater than any in Man's history.

The conference statement goes on to say:

> Many important economic and social decisions are being made today on long-term projects – irrigation, hydro-power, drought

(management), agricultural land use, structural design, coastal engineering and energy planning – all based on the assumption that past climatic data, without modification, are a reliable guide to the future. This is no longer a good assumption.

These conclusions reverberated in a number of national capitals and stimulated a far greater concern on the part of environment and energy agencies as well as key business sectors. As follow-up, the Conference requested the WMO, UNEP and ICSU to establish a small task force on greenhouse gases. This was done in the form of an international Advisory Group on Greenhouse Gases of seven eminent scientists. Subsequent developments in international scientific assessments are discussed in the article Intergovernmental Panel on Climate Change (IPCC): an Historical Review, Volume 4.

The scientific community through the Villach conferences, coordinated by UNEP, WMO and ICSU, thus set the stage for the formation of IPCC in 1988, the Second World Climate Conference 1990, the signing of the UN Framework Convention on Climate Change in 1992, and the Kyoto Protocol to the Convention in 1997. While environmentalists may feel that action on this issue has been slow, others may see the rate at which the world has responded as remarkably swift for such a socially and economically profound issue.

The author was chair of Villach 1985.

JIM BRUCE *Canada*

Volvo Environment Prize

Mostafa K Tolba
International Center for Environment and Development, Cairo, Egypt

Volvo established the Volvo Prize Foundation to promote - without pro t motive by an individual or organization - scienti c research in the eld of environmental protection through the annual award of a prize, designated the Volvo Environment Prize, to an institution, organization, individual or other recipient that has demonstrated outstanding scienti c innovativeness in the area of environmental protection.

The Volvo Prize is one of the major environmental prizes. The Volvo Corporation saw that the threats posed by pollution of the biosphere and the loss of its resources are evident today and all human activity has an impact on the environment. The landscape is changed, the quality of air and water deteriorates, and ef uents and noise increase. Over the past few decades, a consensus has been spreading across the social, industrial and political spectrum about the urgent need to show greater care for Earth's ecosystems and their management.

Volvo also felt that the reality of environmental protection demands a system approach involving the entire life cycle of a product from conception to design, production, use and, finally, recycling or disposal. It is only by taking such a global view of the problems that we will be able to solve them effectively. Deep and current knowledge is essential to be able to choose the right priorities in the environmental field. The new results that research is presenting are therefore a necessity for both industry and society in general. By presenting an annual environmental prize, Volvo wants to attract attention to extraordinary research efforts and encourage scientists whose work and discoveries are of decisive importance to our future. The creation of the Volvo Environmental Prize was meant to be an expression of Volvo's awareness of the interdependence of all actions, inventions and processes that sustain and protect the environmental base.

A comprehensive nomination and selection procedure has been developed to ensure that those who are awarded the Volvo Environment Prize meet the requirement of having made outstanding innovations or discoveries – scientific, socio-economic or technological – which have direct or indirect significance in the environmental field and are of global or regional importance.

The Prize rewards achievement, and priority is given to an individual or group of named individuals rather than to an institution.

Employees or companies within the Volvo Group, including parties who performed research on behalf of the Volvo group, are not eligible to receive the award.

The Foundation capital now totals SEK 20 million allowing a total annual prize sum of SEK 1.5 million. The Volvo Environment Prize is awarded annually to one or more individuals or organizations that the international Prize Committee deems to have made an outstanding innovation or discovery in the environmental field, e.g., in areas such as environmental control, pollution, hazardous waste, food, agriculture or nature and wildlife.

Candidates for the Volvo Environment Prize are nominated by universities, research institutes and their staffs, by scientists and engineers in the fields of environmental protection, life sciences, earth sciences and social sciences, by national academies of science and their staffs as well as by other persons and organizations, all over the world.

The Scientific Committee makes an initial screening and evaluation of candidates and presents its findings and a number of options to the Prize Committee. The

responsibility for selecting the laureate or laureates of the annual Volvo Environment Prize for recommendation to the Board of the Foundation lies with an international Prize Committee.

Matters relating to the Volvo Environment Prize are handled by Mr Claes Beyer, Acting Member of the Board of the Volvo Environment Prize Foundation, and Dr Lena Gevert, Director Environmental Affairs AB Volvo.

Further information on nomination procedures, as well as nomination forms, can be obtained from: The Volvo Environment Prize Foundation, Ms Kikki Hugestrand, Volvo Event Management, S-405 08 Goteborg, Sweden. Tel.: • 46-31-59-66-77; Fax: • 46-31-53-84-31, E-mail: vhk.huge@memo.volvo.se.

WZ

Ward, Barbara

(1914- 1981)

A British economist and author, Barbara Ward was among the first persons to integrate a concern for international development and poverty reduction with a concern for environment and sustainable development. From the late 1940s, she was among the most persuasive supporters of international development through her books, her writing for *The Economist*, her teaching at Harvard University and later as the Albert Schweitzer Professor of international economic development at Columbia University. From the late 1960s, she brought to her concern for development a growing concern about the environment. Amongst her many books, perhaps *Only One Earth: Care and Maintenance of a Small Planet* (co-authored with René Dubos) and published in 1972 was the most in uential. Written to bring the latest environmental knowledge to a popular audience, the book describes the concerns that had led to the organization of the United Nations Conference on the Human Environment in Stockholm in 1972. This is among the first books to draw together a concern for care and maintenance of the environment with a commitment to meeting human needs. Its contribution to the definition of sustainable development can be seen in its statement, 15 years before the Brundtland Commission's report *Our Common Future*, that the charge of the United Nations to the (Stockholm) Conference was to clearly define what should be done to maintain the Earth as a place suitable for human life not only now, but also for future generations (page 25). Her later books (*The Home of Man* published in 1976 just before the United Nations Conference on Human Settlements in 1976 and *Progress for a Small Planet* published in 1979) amplified and developed this theme. She also chaired the symposium in Mexico in 1974, organized by the newly formed United Nations Environment Programme and the United Nations Council on Trade and Development (UNCTAD) which produced the Cocoyoc Declaration; this declaration and her report of the Cocoyoc meeting were in uential in emphasizing the need for development (and international development agencies) to be more environmentally responsible (*see* UNCTAD (United Nations Conference on Trade and Development), Volume 4). At that time, few development assistance agencies had made any provision to consider the environmental implications of what they funded.

For the last decade of her life, Barbara Ward devoted much of her time to building the International Institute for Environment and Development (IIED) with David Runnalls. She saw IIED as the means of ensuring that her concerns about the environment and her strong commitment to social justice would outlive her. She made IIED an independent policy research institute whose task was to help set the policy agenda for environment and development for governments and for international agencies. Within this institute, she helped set new precedents for North–South partnerships, much of its work being of the form of collaborative research with groups in Africa, Asia and Latin America. She also recognized the need to combine rigorous research with strong public advocacy, as can be seen in the creation of *Earthscan* in 1976, initially as a media information unit within IIED, before developing into a leading independent publisher of environment and development books.

Barbara Ward's in uence was not only through her writing but also through her public speaking, her contributions to radio and television programs and her capacity to cajole and persuade those she advised. She was a very gifted public speaker. Her obituary in *The Economist* noted that she had been

> a conscience and provider of fresh ideas, a spur and enthuser, a phrasemaker, provoker and counsellor to one pope and handfuls of cardinals and archbishops, to two American presidents and handfuls of their senior advisors, to British and countless other prime ministries and ministers of rich and poor governments alike, to successive presidents of the World Bank •••

She was knighted and also given a life peerage, becoming Baroness Jackson of Lodsworth, DBE.

DAVID SATTERTHWAITE *UK*

Watson, Robert T

(1948-)

Robert T Watson is Director for Environment and Head of the Environment Sector Board at the World Bank. In September 1997, he became the Chairman of the Intergovernmental Panel on Climate Change (IPCC).

In May 1996, Dr Watson joined the World Bank as Senior Scientific Advisor at the Environment Department. Before joining the Bank, he was Associate Director for the Environment in the Office of Science and Technology Policy in the Executive Office of the President in the White House. Prior to joining the Clinton White House, Dr Watson was Director of the Science Division and Chief Scientist for the Office of Mission to Planet Earth at the National Aeronautics and Space Administration (NASA).

Dr Watson has played a key role in the negotiation of global environment conventions and the evolution of the Global Environment Facility (GEF). At the critical stages of the negotiations of the Montreal Protocol he led a meeting of Ozone Modeling Groups which settled the argument over whether the stratospheric ozone is being depleted or not. He then chaired the extremely important and powerful Montreal Protocol assessment panels during the period that saw huge participation in the Protocol and the establishment of the Multilateral Fund.

From 1991 to 1994, he served as Chairman of the GEF's Scientific and Technical Advisory Panel. He was Chair or Co-Chair of a number of international scientific assessments, including IPCC Working Group II, the United Nations Environment Program-World Meteorological Organization (UNEP-WMO), International Scientific Assessment of Ozone, and UNEP's Global Biodiversity Assessment. Dr Watson has testified in the US Congress on numerous occasions regarding global environmental issues.

Dr Watson received his PhD in Chemistry from London University in 1973 and has received many national and international awards and prizes for his contributions to science, including the American Association for the Advancement of Sciences Award for Scientific Freedom and Responsibility in 1993.

MOSTAFA K TOLBA *Egypt*

WBCSD (World Business Council for Sustainable Development)

The WBCSD (see Figure 1 for logo), is the pre-eminent business voice on business and sustainable development issues. It is a coalition of some 150 international companies united by a shared commitment to sustainable development. Its mandate is to develop closer cooperation between business, government and all other organizations concerned with the environment and sustainable development; to encourage high standards of environmental management in business itself; and to ensure that the right framework conditions are put in place so that business can operate efficiently and make faster progress toward sustainable development.

The WBCSD focuses on: eco-efficiency; sustainability through the market; corporate social responsibility; climate and energy; innovation, technology, society and sustainability; and natural resources. It also benefits from a learning-by-sharing cross-cutting program. Further, a scenario program specializes in synthesizing alternative futures, helping companies develop strategic responses to the sustainable development issues that may affect their business.

With respect to global environment change, the WBCSD has helped create a paradigm shift in the way in which business does business – from a fractured view of environment and development issues to a holistic view of business and sustainable development. Further, the WBCSD has changed the perception of society toward business which is now recognized as a solution provider for sustainable development. Importantly, the WBCSD has initiated a culture of stakeholder dialogues with all constituencies of society. It is also contributing to sectoral industry initiatives to generate momentum for a change in policy and behavior.

The WBCSD currently has five member-led sectoral initiatives: mining and minerals, cement, sustainable mobility, forestry, and sustainability in the electricity utility industry. Members are drawn from 30 countries and 20 major industrial sectors, and the WBCSD also benefits from a global network of national and regional business councils and partner organizations located in the developing world. The WBCSD is governed by a council, composed of the

World Business Council for Sustainable Development

chief executive officers of its member companies, which meets once a year. Between council meetings, WBCSD's activities are managed by an Executive Committee and administered by the President, whose office is at 4, chemin de Conches, CH-1231 Conches-Geneva, Switzerland. WCED (World Commission on Environment and Development)

How far have we advanced in achieving a common understanding of environmental issues? Where are we heading? And what are our ultimate goals? These were some of the questions raised at the celebrations of the tenth anniversary of the Stockholm conference that took place at the headquarters of the United Nations Environment Program (UNEP) in Nairobi in 1982. In an endeavor to provide answers to these questions, the Governing Council (GC) of UNEP decided to prepare an Environmental Perspective to the Year 2000 and Beyond. For this purpose, the Council established its own intergovernmental preparatory committee. A Special Commission, comprised of eminent international figures, would assist the GC in this exercise, in addition to its work in addressing the broader issue of environment in the global *problematique* (GC decision 11/3 of 1983). The General Assembly (GA) of the United Nations endorsed the recommendations of the GC (GA resolution 38/161 of the 19th of December 1983), and suggested that the Special Commission (which became known afterwards as the WCED) should focus mainly on the following terms of reference for its work:

1. To propose long-term environmental strategies for achieving sustainable development to the year 2000 and beyond.
2. To recommend ways in which concern for the environment may be translated into greater cooperation among developing countries and between countries at different stages of economic and social development and lead to the achievement of common and mutually supportive objectives which take account of the interrelationships between people, resources, environment and development.
3. To consider ways and means by which the international community can deal more effectively with environmental concerns, in the light of the other recommendations in its report.
4. To help to define shared perceptions of long-term environmental issues and of the appropriate efforts needed to deal successfully with the problems of protecting and enhancing the environment, a long-term agenda for action during the coming decades, and aspirational goals for the world community, taking into account the relevant resolutions of the session of the special character of the GC of UNEP in 1982.

The WCED was composed of 21 members from different countries appointed in their individual capacities. Mrs Gro Harlem Bruntland of Norway was appointed chairperson of the Commission, and Dr Mansour Khalid of Sudan was appointed vice-chairman.

The work of the WCED began in May 1984 and in July 1984 a WCED Secretariat was established in Geneva. Dr Jim MacNeill (Canada) was appointed as secretary general, and the secretariat consisted of 15 professional staff members. In October 1984, the WCED selected eight key issues for analysis during the course of its work:

- perspectives on population, environment, and sustainable development;
- energy, environment and development;
- industry, environment and development;
- food security, agriculture, forestry, environment and development;
- human settlements, environment and development;
- international economic relations, environment and development;
- decision support systems for environmental management;
- international cooperation.

The WCED held a number of deliberative meetings and/or public hearings in all regions of the world to get a first-hand view of environment and development issues in those regions. The work of the WCED was carried out by special working groups and advisory panels. The commission also engaged experts, research institutes, and academic centers of excellence from around the globe to prepare more than 75 studies and reports relating to the above-mentioned eight issues for the Commission's review and consideration. In April 1987, the WCED published its report under the title *Our Common Future*, familiarly known as the Bruntland report (WCED, 1987).

WFC (World Food Council)

The WFC was established on 17 December 1974 by the General Assembly resolution 3348 (29) on the recommendation of the World Food Conference held in Rome in November 1974, as a United Nations (UN) organ reporting to the General Assembly through United Nations Economic and Social Council (ECOSOC). Its mandate was to review periodically major problems and policy issues affecting the world food situation and the steps being proposed or taken to resolve them by governments, by the UN system and its regional organizations and to recommend remedial action as appropriate. The Council consisted of 36 members nominated by ECOSOC and elected by the General Assembly with due consideration to balanced regional representation.

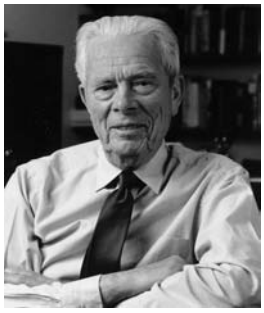
Until 1993, the WFC had its main headquarters in Rome and was serviced by an executive director and a small secretariat. Following the adoption of General Assembly resolution 47/212 (B) on May 6th 1993, the post of executive director was disestablished and the functions and activities previously carried out by the WFC Secretariat were transferred to the UN Department for Policy Coordination and Sustainable Development in New York.

On July 1st 1996 General Assembly resolution 50/227, implementing measures for the restructuring and revitalization of the UN in the economic, social and related fields, was adopted. Paragraph 72 concerns WFC: The functions of the World Food Council shall be absorbed by the Food and Agriculture Organization of the United Nations and the World Food Program, and consequently the World Food Council is discontinued .

HENRI CARSALADE *Italy*

White, Gilbert

(1911-)



Gilbert F White (born 1911) is one of the world's best known and most admired environmental scientists. For over half a century he has initiated new thinking across a wide range of fields including water supply, ood hazards, river basin development, arid zone problems, energy policy, natural resource management and decision-making, environmental perception and behavior, and global environmental change. His geography PhD dissertation *Human Adjustment to Floods* (University of Chicago, 1942) set in motion a radical reassessment of public policy to encourage more appropriate human use of hazardous areas as opposed to the reliance on engineering works to protect them. The concept of human adjustment has served as a practical guide to action; as for example in the new disaster mitigation policies of the US Federal Emergency Management Agency, as a widely applied research paradigm, and as an early aspiration for human reconciliation with the natural world.

White's first positions were as geographer with the Mississippi Valley Committee, the National Resources Committee, and the National Resources Planning Board in President Franklin Roosevelt's Administration. As a Quaker and a conscientious objector in the Second World War he served with the American Friends Service Committee in France and Germany, where he was interned and spent 1 year in detention. The program in which he participated was awarded a Nobel Peace Prize.

After the war White served as President of Haverford College until 1956 when he returned to Chicago as Chair of the Department of Geography. He remained at Chicago until moving in 1969 to the University of Colorado at Boulder to assume the Directorship of the Institute of Behavioral Science. At Colorado, he is currently the Gustavson Distinguished Professor Emeritus of Geography and continues to be actively and widely engaged in global environmental issues, and to be involved with the Natural Hazards Research and Applications Information Center, which he founded in 1975.

Some of White's most important international contributions to environmental science were made during his two-term presidency (1976–1982) of the Scientific Committee on Problems of the Environment (SCOPE), a body formed in 1969 as part of the International Council for Science (ICSU) (*see* ICSU (International Council for Science), Volume 4). Under White's guidance, SCOPE began to address environmental problems at a global scale, and established itself as a reliable source of scientific advice for governments and organizations concerned with the quality of the global environment. With White's insight and leadership, SCOPE laid the scientific groundwork for the worldwide interest in global environmental issues. In particular, SCOPE's work with biogeochemical cycles provided the scientific basis for the International Geosphere Biosphere Program that has engaged scientists from many countries. White has also been especially in uential in fostering a partnership of effort between social scientists and natural scientists. During the Cold War years, Gilbert White maintained strong links with Russian scientists which helped to keep open the doors of communication through some difficult times. Russian collaboration was important

in the International Geographical Union's Commission on the Environment and its international project to study and compare adjustments with natural hazards.

Gilbert White is also known for his tireless efforts to apply his scientific knowledge to the promotion of peace and the resolution of con icts. Such motivation lay behind his chairmanship of the Ford Foundation Project on the Lower Mekong River (1964) and subsequent attempts to bring warring nations to the table in the interests of improved river basin management. As President of SCOPE, White raised foundation funds and organized a coalition of world scientific organizations to study (between 1983 and 1988) the environmental effects of nuclear war (the so-called *nuclear winter hypothesis*) and served on the international Steering Committee throughout the study. Most recently, he has helped to bring scientists from Israel, Palestine, and Jordan together in a commonly agreed and accepted study of the waters of the Jordan River.

Gilbert's late wife, and frequent collaborator, Anne White joined with him and David Bradley, of the London School of Tropical Hygiene and Medicine, in a landmark study of the decisions made in the procurement and use of domestic water supplies in East Africa. Published under the title *Drawers of Water* in 1972, the research changed government attitudes towards the quantity and quality of water investments for millions of people. It was certainly the most in uential research work I have done in terms of affecting the lives of people, says White. This study is now being repeated to assess the changes a generation later.

The range and depth of White's public and scholarly contributions is evident not only in his own over 300 publications, and in the large number of leadership roles he has played in many diverse organizations (including the US National Research Council, UNESCO, ICSU, the International Geographical Union, The International Social Sciences Council, Resources for the Future, and the American Friends Service Committee), but also in his receipt of many prizes and awards, and in what others have written in honor of his work. A *festschrift* (Kates and Burton, 1986) includes 13 essays by authorities in fields to which he has contributed, and a companion volume includes 29 of White's most in uential papers.

Anne once wrote of her husband: What makes him keep at this? I think it is all tied together by his Quaker faith in the ability of humans to marshal their inner resources to deal competently and lovingly with the outer world and with their fellow human beings. Then there is the real fun he gets out of the exchange of ideas with others, and the challenge of making real friends, not just co-workers, out of those others. And not least, there is his innate and humble desire to leave the world a bit better place than he found it.

In May 2000, Gilbert White was awarded the Public Welfare Medal of the US National Academy of Science, and in December 2000 President Clinton presented him with the National Medal of Science.

WHO (World Health Organization)

The World Health Organization (WHO) was founded in 1948, as a specialized agency of the United Nations (UN). WHO is the directing and coordinating authority on international health work, with the aim of the attainment by all peoples of the highest possible level of health. It has 191 member states, whose interests are represented in the World Health Assembly (WHA), which is the decision-making authority, and the secretariat. The WHA meets every year, in Geneva, to decide policy matters, and approve the operational budget of WHO. The WHA is guided in decision making by an executive board composed of 32 individuals technically qualified in the field of health. Each member of the board is nominated by a designated member state and serves a three-year term. The Board meets at least twice a year. The key functionary of WHO is the director-general. Any member state may nominate a candidate, who meets a defined set of criteria, to the position of director-general. The candidate subsequently makes a presentation before the WHA. The position is filled by the candidate elected by simple majority (secret ballot) by members of the WHA.

WHO carries out its mandate through a highly decentralized network comprising six regions. Only 30% of WHO staff work in the headquarters at Geneva. One-quarter of WHO staff work in the regional offices. Each region has a regional committee and a regional office. At the head

of each regional office is a regional director. The regional offices formulate WHO policies to meet their specific needs. The offices function under the following acronyms: PAHO (Pan American Sanitary Bureau), EURO (Regional Office for Europe), AFRO (Regional Office for Africa), EMRO (Regional Office for the Eastern Mediterranean), SEARO (Regional Office for South-east Asia) and WPRO (Regional Office for the Western Pacific).

Within each region, member states frequently have a WHO representative, to support the government in the planning and management of national health programs, and to carry out the offices of WHO. Almost half of all WHO staff work is at the country level.

Health, as defined in the WHO constitution, is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity. Within this context, WHO strives to:

- stimulate the eradication of epidemic, endemic, and other diseases by promoting improved nutrition, housing, sanitation, working conditions, and other aspects of environmental hygiene and by promoting research in the field of health and cooperation among scientific and professional groups which contribute to the enhancement of health;
- provide information, counsel, and assistance in the field of health; and to establish and maintain such administrative and technical services as may be required, including epidemiological and statistical services;
- propose international conventions and agreements on health matters and promote technical cooperation, furnish appropriate health services, technical assistance and, in emergencies, necessary aid, upon the request or acceptance of governments;
- promote improved standards of teaching and training in the health, medical and related professions; establish international standards for biological, pharmaceutical and similar products, and standardize diagnostic procedures;
- foster activities in the field of mental health, especially those activities affecting the harmony of human relations.

WHO leads the world alliance for health for all, an initiative to assure that global resources for health are evenly distributed and that essential health care is accessible to everyone.

Among its major accomplishments have been the eradication of smallpox and yaws, reduction in mortality and increase in life expectancy, delivery of essential drugs, introduction of environmental sanitation measures, and provision of guidelines for healthier cities. WHO is at the threshold of controlling other major diseases such as leprosy and poliomyelitis. WHO monitors diseases with epidemic and pandemic potential such as tuberculosis (TB), human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) and viral hemorrhagic fevers like Ebola. WHO takes an integrated, coordinated approach to prevent, treat, rehabilitate, and where possible, cure major non-communicable diseases such as cardiovascular disease, cancers and respiratory diseases. This involves a systemic approach to disease-specific interventions, by the application of cost-effective methods of detection and management and major sustained global campaigns to encourage healthy lifestyles, healthy public policies and acceleration of research. WHO helps safeguard ethical standards by stimulating discussion and setting global guidelines on topics of biomedical concern, such as cloning, and human drug-testing.

WHO works closely with other organizations in the UN system, and with bilateral agencies, intergovernmental and non-governmental organizations, and with health-related institutions around the world, officially designated as WHO collaborating centers.

WHO recognizes that health, and the pursuit of health for all, can only be assured in healthy environments. As such, much of its work is focused on environmental elements vital to the protection and promotion of good health. These include air quality, drinking water, solid and hazardous wastes, water supply and sanitation. WHO pays special attention to climatic change and such by-products of industrialization as ultra-violet and other radiation, chemical waste production, and electromagnetic fields (EMF). Through its Healthy Cities project, WHO collaborates with local governments and other UN agencies, such as the United Nations Environment Programme (UNEP) and the Food and Agriculture Organization (FAO) (Joint FAO/WHO Meeting on Pesticide Residues (JMPR), 1990), to conduct research into and implement suitable programs for the protection of environmental health. With its partners, WHO produces methodology workbooks for professionals (WHO, 1994), textbooks and guides (Lwanga *et al.*, 1999) for school use, as well as summary reports of its findings (WHO, 1999), from meetings, conferences, research and other professional consultations. These are useful for enhancing public awareness of and investment in the protection of the whole living environment, but also in expanding the knowledge base of professionals across sectors in the interrelation of their work, and in the need for inter-sectoral solutions to health, environmental and other problems.

World Commission on Environment and Development (WCED)

Jim MacNeill
Ottawa, Canada

On October 1st, 1984, the 23 members of the newly appointed WCED sat down together for the first time in Geneva to confront the interlocking issues of development, growth, population, resources and environment. As Secretary General, I thought of it this way: If the world's population doubles over the next 40- 50 years, can we increase food production by a factor of four, energy use by six, and income by about eight (much more evenly distributed, of course), without at the same time pushing the planet beyond certain critical thresholds that we are only now beginning to understand? Or, to put it another way, can growth on the scale needed to meet future needs and aspirations be managed on a basis that is sustainable? I called that the sustainability question.

Three years later, on October 19th, 1987, the Commission presented its report, entitled Our Common Future, *to the United Nations (UN) General Assembly in a special plenary debate (The World Commission on Environment and Development, 1987; MacNeill, 1989). When the debate was scheduled, no one knew that October 19th was to become known as Black Monday, the day the New York Stock Exchange dropped by 502 points. That knocked the debate off the front pages, but it also dramatically underscored the Commission's answer to the sustainability question. The answer was: "Yes ••• but •••." The 'but' conveyed a large number of proposals for fundamental changes in the way we manage the planet.*

One of the familiar quotations of our times is to be found in Our Common Future. *It is the de nition of* Sustainable Development: "*meeting the needs of the present without compromising the ability of future generations to meet their own needs.*"

The Commission's proposals went well beyond the expectations of the General Assembly when, 4 years earlier, in the fall of 1983, it debated and, by consensus, reluctantly adopted a resolution calling for the establishment of a special commission (Resolution of the General Assembly 38/161, United Nations, 1983). The resolution, proposed by the United Nations Environment Programme (UNEP) Governing Council, had been under consideration for more than 1 year. At its 1982 Special Session in Nairobi, the Governing Council looked back 10 years since the landmark Stockholm Conference of 1972 and congratulated itself on a decade of achievement. Many noted, however, that the achievements were concentrated mainly in the richer countries of the Organisation for Economic Cooperation and Development (OECD). They could afford the often high costs of react-and-cure environmental protection strategies. The poorer countries of the developing world could not and, during the decade since Stockholm, they had experienced a steady decline in environmental and resource trends.

Others noted that while environmental protection treated the symptoms of the underlying trends in both rich and poor countries, the sources of the trends in business-as-usual economic development were growing much more rapidly and were reinforcing and accelerating the downward spiral of environmental and resource degradation. The production and consumption patterns of the rich, combined with the pervasive poverty and exploding populations of the poor, put pressures on the environment of an intensity never seen before. Projecting the trends to 2000, it was clear that, without a change of course, environmental degradation, poverty and misery in many countries would get steadily worse.

The General Assembly debate in the fall of 1983 revealed that leaders in many governments had serious reservations

about the establishment of a special commission. Some felt that to support it was to admit that current approaches to managing the environment (and, perhaps, even development) were awed. They were right, of course. Some feared that a commission would come out with yet another study predicting inevitable doom and bewailing growth. They were wrong. Others feared that an independent commission would make recommendations they would not want to support but could not oppose without political cost. They too were right, as the experience of the past 16 years has shown.

The resolution finally adopted by the General Assembly was long, even by UN standards. It was marked by vague have-it-both-ways language, and riddled with convoluted and contradictory compromises. Since any attempt to follow it would have doomed the commission to failure, one of the first things that the Chairman, Gro Harlem Brundtland and I agreed was that we would together reinterpret the resolution to provide the commission with a name and with meaningful terms of reference. We later agreed that the commission would be known as the WCED. We also agreed that the General Assembly had, in effect, asked the Commission to propose a new global agenda for change. The WCED would have three objectives: to take a fresh look at the critical issues of environment and development and bring in some practical recommendations for dealing with them; to propose new forms of international cooperation on these issues; and to raise the levels of understanding and commitment to action by individuals, voluntary organizations, businesses, institutes, and governments. And, finally, we insisted that the General Assembly had agreed that the Commission was an independent body linked to, but outside the control of, governments and the UN system.

GETTING STARTED

In December, 1983, Secretary General Perez de Cuellar invited Mrs Gro Harlem Brundtland (then Leader of the Opposition, later Prime Minister of Norway, and now Director General of the World Health Organization) to be Chairman of the Commission, and Dr Mansour Khalid, one time foreign minister of the Sudan, to be vice chairman. A month later, in January, Mrs Brundtland called me in Paris, where I was Director of Environment for OECD, and asked me to become Secretary General. I agreed to consider it and, in the meantime, to advise her on the organization of the Commission. Subsequently, in consultation with me, she and the vice-chairman appointed the other members of the Commission. We were 23 in all, from 22 different countries, regionally balanced, including all of the major power groups, and with a strong majority of 14 from developing countries.

Before agreeing to accept the Chairman's invitation to become Secretary General, I had to persuade myself that there was a fighting chance to achieve a positive result. Following an OECD meeting in London in March 1984, I retreated to a quiet hotel for five days to think it through. I had already consulted with colleagues in OECD and with top officials in environment, foreign affairs and many other sectors in more than two dozen countries. To clear my mind, I drafted a statement on the key issues confronting the Commission, as I saw them, and on the substance and strategy of the inquiry it should pursue. In the process, I became convinced that, with a bit of luck, a lot of hard work, and about $8 000 000 in voluntary contributions, the task was do-able. After confirming that the concepts in my statement, which I entitled *Mandate for Change*, would enjoy the Chairman's broad support, I agreed to become Secretary General.

MANDATE FOR CHANGE

I put my statement before the Commission at its first full meeting in Geneva in October 1984 (The World Commission on Environment and Development, 1984). Concerning the work program, the essential choice was clear. We could take the easy route and adopt a standard agenda, basically the traditional list of environmental problems, or we could pioneer an alternative agenda integrating development and environment.

Concerning the method of inquiry, the choices were also clear. We must do all of the normal things one would expect of a commission of inquiry – contract the best advice, establish high-level panels, and invite distinguished people to meet with us. In addition, I proposed two things that had not been done before: first, that we hold open public hearings on every continent; and second, that after completing our report, we extend the life of the Commission by nine months to ensure that the recommendations were presented to governments, industry, non-government organizations and the media in a series of meetings around the world.

The proposal for public hearings met with some difficulty. It arose out of my experience with OECD, where I introduced the idea of public meetings in the OECD 1979 review of New Zealand's environment policy. Some Commissioners pointed out that, under the UN resolution, we had no authority to conduct public hearings. In fact, they argued, to consult civil society on issues that were highly sensitive and controversial could and would be seen by governments hosting us, as an infringement on their national sovereignty. We had already received invitations from several governments to hold our meetings in their countries and I suggested that we make our acceptance conditional on agreement by the host government to allow us to organize such hearings. The Commission agreed. The hearings

went on to become the Commission's hallmark and, in my view, the primary source of the hard-won consensus on the issues before it.

The proposal for a post-report advocacy phase met with even greater difficulty. It arose from what I had learned about the fate of the recommendations of earlier Commissions, such as Brandt and Palme, which had simply published their reports. Many commissioners argued for a similar policy. The UN Resolution gave us no authority to extend our life, they said. Our obligations ended with the publication of our report. Nevertheless, they did agree to allow the proposal to remain in the work program and, when I secured the necessary funds, it was fully embraced by all commissioners. In the event, this proved to be a major reason why the report was so well received and so successful in changing the terms of the environment/development debate.

In deciding not only to adopt the alternative agenda, but also to include public hearings in its strategy of inquiry, the commission gave itself a chance to take a fresh look at the issues and to come up with some meaningful recommendations for change. With a budget of around $8 000 000, which it also adopted, it gave itself a license to find the resources needed. My statement, *Mandate for Change*, was published with few modifications as its point of departure for global consultations.

A GLOBAL CONSULTATION

Some 900 days later, at the end of February 1987, the Commission concluded its deliberations on *Our Common Future* at its final meeting in Tokyo. A full consensus had been reached on a diagnosis of the key issues of environment and development, and on a global agenda for change to manage the growing risks and opportunities challenging the world community. A political document, *Our Common Future* was to be hailed by major economic and environmental journals and by leaders in the government, corporate, scientific and non-governmental world as the most hopeful and useful report on environment and development to appear in two decades.

But the Commission had gone down to the wire on a number of issues. Energy, with its many unresolved dilemmas, and with the emotions surrounding nuclear energy reinforced by Chernobyl, had resisted several attempts at consensus. In Tokyo it kept Commissioners going several nights and provided the stuff of drama. Population, security, Antarctica, international economic relations and, of course, institutional reform proved almost as difficult.

Between its second meeting in Jakarta and the final moments in Tokyo, the Commission had achieved agreement from initially wide and, on some issues, fundamental disagreement. Composed of political leaders – present and former ministers of foreign affairs, finance, energy, population, environment and many other portfolios – industrialists, scientists and senior administrators, the Commissioners represented almost every shade of ideology, academic background and personal experience (for a list of Commissioners, see The World Commission on Environment and Development, 1987, Annex 2). They served in a personal capacity, but national, cultural and group loyalties were strong and manifested themselves in many ways. Tackling some of the most complex issues facing humankind, issues loaded with questions of power, equity and justice, the group had a built-in potential to blow itself apart. But it did not. Why?

The question remains and the answers vary depending on one's perspective. From my perspective as Secretary General, a few things stand out. The agreement reached at its first meeting on an alternative agenda and a strategy for the inquiry was fundamental. The capacity of commissioners to rise above their differences and to search for and ultimately find common ground was evident from the beginning. It was aided by a compelling sense of the urgency of the issues of global change, and a growing conviction that the approaches to management then in place were deeply awed and that change was essential. The brilliant reports of our expert panels and the work of a dedicated secretariat and excellent consultants and advisers provided basic support. All of these were essential to the consensus, but they were not sufficient.

Commissioners skirmished with each other for months before we finally broke through the diverse cultural and ideological skins that we all brought to the table. And, in my view, we broke through finally only because of the public hearings and site visits that we organized in every part of the globe.

The hearings enabled Commissioners to hear the testimony of nearly 1000 experts and concerned citizens on five continents. They gave us direct exposure to the issues on the ground and direct contact with the people living the issues. They provided us, almost complete strangers at the beginning, with a common base of information and a common set of experiences. For two days, sometimes three, Commissioners listened to testimony delivered with conviction and often with great emotion. Dialogues with ministers, experts and ordinary people on the front line of the interface between environment and development, helped to tear down the normal barriers of communication in the subsequent, closed meetings of the Commission.

I recall many incidents in Brazil, Indonesia, Norway, USSR, Zimbabwe and Canada. We not only invited groups and individuals to come to our hearings, but where necessary we took our hearings to them. We went to East Kalamantan to see ancient tropical forests being mined for timber and to talk to local groups struggling with problems that most commissioners could not even imagine. We ew to the highlands of Zimbabwe where the land had been

sheared of trees, compromising prospects for development. In Sao Paulo, the leaders of several Indian nations were present, their homelands threatened by massive deforestation. Electricity seemed to jump from the eyes of the first who spoke when he declaimed: I am the son of a small nation ••• dying and as we die insisting that there is only one place for us to live. Two days later, when the Chairman tried to close the hearing long after the scheduled hour, they crowded the railing shouting You must not stop. We have so much more to say, and you will not be back!

The public hearings and site visits revealed the heavy contradictions between the reality of environment and development totally interlocked in the daily lives of people, industries and communities, and the unreality of the distinctions between them made in our academic, economic and political institutions. They brought a new dimension to the information and analyses provided by our consultants and expert panels. They also provided a context within which to understand the series of disasters that grabbed the world's headlines during the 900 days of the Commission's work: the drought-triggered human and ecological catastrophe in Ethiopia, the Sahel and elsewhere in Africa; the great fire of East Kalamantan; the chemical disasters in Bhopal, Mexico City and the Rhine; the growing rate of forest death in Europe; the fresh warnings on climate change; the stratospheric ozone hole and Chernobyl.

Environmental crisis was seen to be a euphemism for what in reality is a failure of economic and other development policies, and the institutions behind those policies. Following each hearing, I observed commissioners with an environmental background and those with a development background, moving closer to an ever-widening consensus based on a shared understanding of actual situations and the issues arising from them.

SUSTAINABLE DEVELOPMENT

Looking forward to the 21st century, the Commission saw a world filled with opportunities and risks without parallel in human history. Human ingenuity in science and technology have resulted in enormous gains, and have provided the tools to shape an even more promising future. But these same forces have also given rise to a range of new risks and many of them represent clear and ominous threats to our common future.

These opportunities and risks, said the Commission, stem from two colliding sets of trends. First, the world's population and its economic and technological systems are on the greatest growth track in all of history. Second, even with current levels of population, business-as-usual economic growth threatens to drive the earth's ecological systems past critical thresholds essential for future development and even survival. These colliding trends are accentuating rich–poor differences within countries and among nations, and they are compounding the problems of cooperatively managing the risks to our common future.

Growth on the scale required to meet present and future needs would entail a further rapid expansion of the world economy, perhaps by as much as five to ten times over the next half century. A five- to ten-fold increase over 50 years sounds enormous, but it actually re ects annual growth rates of only 3.2 and 4.7%. In many developing countries, that is hardly enough to keep up with projected rates of population growth, let alone reduce levels of poverty.

The Commission recognized that such growth could translate into a colossal new burden on the environment. Concerning energy alone, for example, the Commission found that if nations were to employ current forms of energy use, energy supply would have to increase by a factor of five, just to bring developing countries, with their present populations, up to the level of consumption now prevailing in the industrialized world. Critical life-support systems would collapse long before reaching those levels.

A new development path was required, one that sustained human progress not just in some areas for a few years, but everywhere for the indefinite future. The Commission was convinced that humanity has the ability to make development sustainable, a concept that the Commission defined in various ways, most famously as development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

With the publication of *Our Common Future*, the concept of sustainable development spread rapidly through the corridors of government, industry, media and civil society. Today, it trips off the tongues of Presidents and Prime Ministers, editorial writers, academics and priests, as well as protest marchers in Seattle, Washington and elsewhere. The concept goes far beyond sustainability in the environmental sense. It is a broad concept for social and economic progress that has the potential to provide new insights for institutional reform and inspiration for international cooperation (see Box 1).

Sustainable development, the Commission found, requires strong measures to change both the content and the quality of growth and equally strong measures to ensure a more equitable distribution of the proceeds of growth,

Box 1 Strategic imperatives for sustainable development (WCED, 1987)

The Commission identified a number of broad directions that development must take if it is to be sustainable. It called these the strategic imperatives for sustainable development and it focussed on seven of them: reviving growth; changing the quality of growth; meeting essential needs for jobs, food, energy, water, and sanitation; ensuring a sustainable level of population; conserving and enhancing the resource base; reorienting technology and managing risk; and merging environment and economics in decision making.

nationally and internationally. *Our Common Future* has a number of recommendations in this regard, in the fields of international economic relations, energy, industry, agriculture, the management of the global commons, and new concepts of security which go beyond military security.

In the Commission's view, the principal development challenge is to meet the needs and aspirations of an expanding developing world population, especially those who live in absolute poverty and are unable to satisfy even their most basic needs. Meeting essential needs requires not only a new era of economic growth for nations in which the majority are poor, the Commission said, but an assurance that those poor get their fair share of the resources required to sustain that growth. Such equity would be aided by political systems that secure effective citizen participation in decision making and by greater democracy in international decision making.

Urgent steps are needed to limit population growth. Sustainable development can be pursued more easily when population size is stabilized at a level consistent with the productive capacity of the ecosystem. The Commission pointed out, however, that the issue is not simply one of global population size. Providing people with facilities and education that allow them to choose the size of their families is essential and, for women, a basic human right of self-determination. Population policies must be integrated with other economic and social development programs such as health care and the provision of livelihoods.

Repeatedly, the Commission stressed that sustainable development involves more than growth. It requires a change in the content of growth to make it less material- and energy-intensive and more equitable in its impact. In economic terms, it means living off the earth's interest, without encroaching on its capital. It also means investing to sustain and even enhance the earth's present capital stocks of environmental resources, so that future dividends can be ensured and enlarged. Policies to this effect are required in all countries as part of a package of measures to maintain the stock of ecological capital, to improve the distribution of income, and to reduce the degree of vulnerability to economic crises.

If needs are to be met on a sustainable basis, the Earth's natural resource base must be conserved and enhanced. Major changes in policies will be needed to cope with the industrial world's current high levels of consumption, the increases in consumption needed to meet minimum standards in developing countries, and expected population growth. However, said the Commission, the case for the conservation of nature should not rest only with development goals. It is part of our moral obligation to other living beings and future generations.

Sustainable development also requires a reorientation of technology – the key link between humans and nature. Technology development must be changed to pay greater attention to environmental factors. And the capacity for technological innovation needs to be greatly enhanced in developing countries so that they can respond more effectively to the challenges of the future.

The common theme throughout *Our Common Future* is the need to integrate economic and ecological considerations in decision making. Echoing the OECD's finding that the environment and the economy can be made mutually reinforcing, the Commission noted that the compatibility of environmental and economic objectives is often lost in the pursuit of individual or group gains, with little regard for the impacts on others, with a blind faith in science's ability to find solutions, and in ignorance of the distant consequences of today's decisions. Institutional rigidities add to this myopia.

Those responsible for managing natural resources and protecting the environment are institutionally separated from those responsible for managing the economy, whose focus is narrowly concerned with production and growth. Energy utilities produce power, while the acid rain they also produce is left to the ministries of environment. Treasury departments subsidize unsustainable practices in agriculture, forestry, fishing, industry, transport and other sectors, but ignore the consequences for resources and the environment. The challenge is to give the central economic and sectoral ministries the responsibility for the quality of those parts of the human environment affected by their decisions, and to give the environmental agencies more power to cope with the effects of unsustainable development.

The integration of economic and ecological factors into the law and into decision-making systems within countries has to be matched at the international level. Economic interactions through trade, finance, investment, and travel will also grow and heighten economic and ecological interdependence. Hence in the future, even more so than now, sustainable development requires the unification of economics and ecology in international relations.

The ability to anticipate and prevent environmental damage requires that the ecological dimensions of policy be considered at the same time as the economic, trade, energy, agricultural, and other dimensions. They should be considered on the same agendas and in the same national and international institutions. The real world of interlocked economic and ecological systems will not change; the policies and institutions concerned must.

TIME FOR CHANGE

Seven weeks after Tokyo, on April 27th, 1987, the Chairman, in the presence of the Commission, presented *Our Common Future* to the world at a major event in London. Ten years later, it had sold over 1 000 000 copies in nearly 25 languages, surely a record for a UN report.

After the London launch, Commissioners discussed their recommendations with over 100 governments, often directly with the President or Prime Minister. We presented the recommendations to intergovernmental organizations, including the heads of OECD and virtually all of the UN agencies. We discussed them with the heads of the World Bank and the regional development banks. We held seminars, formal and informal, with industrial and non-governmental leaders on every continent. Presenting our report to a head of state or chief executive officer had a great advantage. It meant that their senior officials had to read it in order to prepare a briefing note. As a result, leaders from government, industry and civil society were ready when we presented the report to the UN General Assembly.

The UN commenced consideration of *Our Common Future* in a plenary debate on October 19th, 1987. Prime Minister Gro Harlem Brundtland presented our recommendations in the presence of the UN Secretary General, Prime Minister Gandhi, and many other political leaders who had come to support them.

A dramatic highlight was provided by the President of the small island nation of the Maldives. He galvanized the Assembly with a plea for action to prevent the physical disappearance of his nation. The highest point in the Maldives is less than 2 m above sea level. Most of that nation of 1190 islands is below 1 m, so a 1 m rise in sea level would spell extinction for his nation. To endangered species, humans have added a new category of global risks, endangered nations (see the Commonwealth Group of Experts, 1989). The report speaks of ••• far reaching social and economic effects on low-lying areas, as in Guyana ••• Kiribati, Tuvalu, and other Commonwealth countries ••• They face the prospect of ooding from the sea and greater risk of storm surges, but deeper ooding on inland plains ••• There are potential implications – ••• for agriculture; fresh water supply threatened with salinization; the sitting of towns, factories, power plants and airports; and hazardous waste disposal.

Noting that the next few decades are crucial, the Commission concluded *Our Common Future* with a call for action to break out of past patterns. Attempts to maintain social and ecological stability through old approaches to development and environmental protection will increase instability, it said. Security must be sought through change. To achieve the needed changes, the Commission proposed that the UN General Assembly transform *Our Common Future* into a United Nations Programme on Sustainable Development. An international conference could be convened for this purpose, it said, to promote follow-up arrangements that will be needed to set benchmarks and to maintain human progress. While the General Assembly endorsed all of the Commission's recommendations in principle, on that point, as the world knows, it did act. The result, five years later, was the Rio Earth Summit.

World Conservation Union (IUCN) Red List of Threatened Species

As a way of instituting a standard for establishing the status of threatened species, IUCN has designed and promulgated the Red List of Threatened Species. Based on the work of some 7000 experts who are members of the IUCN Species Survival Commission, the Red List is based on a consistent and objective quantitative system of categories and criteria for listing. The categories include extinct, extinct in the wild, critically endangered, endangered, vulnerable, lower risk, data deficient, and not evaluated. These categories provide an easily and widely understood method for

highlighting those species under a high risk of extinction, helping to focus attention on the conservation measures designed to protect them.

The criteria for listing include population reduction, extent of occurrence, size of population, and probability of extinction, with different parameters leading to the allocations to categories. The 1996 Red List assessed the conservation status of all species of birds and mammals. While coverage for fish and plants is less complete, and for invertebrates is focused on only a few groups (for example, butter ies) coverage of these latter groups is constantly improving.

Red List Authorities (RLA) are being established for all taxonomic groups included on the list, usually the specialist group of the IUCN Species Survival Commission responsible for the species; an exception is birds, where BirdLife International is the designated RLA. The role of RLA is to ensure that all species within their jurisdiction are correctly evaluated against the categories and criteria at least once every 10 years and, if possible, every five years. The Red List Programme has adopted the use of a commercial software package called RAMAS.

The Red List grew out of IUCN's *Red Data Book*, first published in 1996 (for mammals). Dozens of subsequent Red Data Books have been published at global, regional, and national levels, helping to stimulate laws to address the problem of endangered species in many countries. The Red List has been an essential element to communicate the idea of species threatened by extinction, and has generated a global response to the extinction crisis.

The IUCN Red List is now widely recognized as the most comprehensive, balanced, and apolitical global approach for evaluating the conservation status of species of plants and animals. For further information, see http://www.redlist.org.

Worldwatch Institute

Founded in 1974 by Lester Brown, Worldwatch Institute is an independent, public policy research institute widely respected for its pioneering work on sustainable development and the connections between the natural world and human welfare. The institute is one of the world's leading sources of environmental analysis and information.

The institute's mission is to foster the evolution of an environmentally sustainable economy, one in which human needs are met in ways that do not threaten the prospects of future generations. Worldwatch seeks to achieve this goal through conducting interdisciplinary research on global environmental issues and disseminating the results worldwide. The results of its research are distributed through a worldwide publishing network, through close working relationships with the world's major news organizations, and through individuals working in various ways on their own to achieve the institute's goals.

Worldwatch's interdisciplinary approach is highly valued by decision makers in both the public and private sectors, ranging from elected members of national legislatures to corporate planners. The combination of the institute's cutting-edge analysis and accessible writing style means that specialists in particular fields look forward to each new publication. Over the years, the institute has evolved a stable of five publications. They are, in order of launching: the *Worldwatch Papers*, Worldwatch books, *State of the World* (annual), *World Watch magazine* (bimonthly), and *Vital Signs* (annual). The institute also publishes a *Worldwatch Database Disk*, and in

2000 it launched an electronic publication: *Worldwatch Issue Alerts*. Written by Lester R Brown, the Alerts are released via email, fax, and the institute's website • http://www.worldwatch.org/alerts/indexia.html• .

The institute's research is translated through a global publishing network. At present, it has some 175 publishing contracts in effect in over 30 languages, including all of the major languages, such as Arabic, Chinese, French, Japanese, Portuguese, Spanish, and Russian, and many minor ones (see • http://www.worldwatch.org/foreign/index.html•).

The institute has developed a close working relationship with the world's major news organizations and global wire services. The institute and its researchers are cited in, or are bylines of, some 40 stories a day in newspapers and magazines (and associated websites) worldwide. In addition, the electronic media disseminate the results of its research.

REAH JANISE KAUFFMAN *USA*

WRI (World Resources Institute)

The WRI is an independent center for knowledge on global environmental and development issues. WRI provides objective information and practical proposals for policy and institutional change that will foster environmentally sound, socially equitable development. Its stated mission is to move human society to live in ways that protect Earth's environment and its capacity to provide for the needs and aspirations of current and future generations.

WRI works to put ideas into action. Activities are centered around four themes:

1. *Biological resource stewardship*: WRI focuses on halting the degradation of biological resources, particularly in forests and agriculture, and enhancing their contribution to economic development.
2. *Climate protection*: WRI seeks to prevent human-caused climate change by promoting cooperation among businesses and nations, rich and poor, in implementing international agreements, fostering economic opportunity, and developing cleaner energy sources and technology.
3. *Development paths*: WRI works with a worldwide network of partner organizations to help promote development policies that reduce poverty, improve livelihoods, and protect the environment.
4. *Sustainable enterprise*: WRI fosters sustainable enterprises by helping to provide the management strategies and incentives that will enable firms to build future profitability around environmentally friendly products and processes.

Based in Washington, DC, WRI was established in 1982 by James Gustav Speth. It has an international staff of 125, who work with advisors, collaborators, and partner institutions in more than 50 countries. WRI has a Board of Directors of 34 prominent scientists, international policy makers, and corporate managers.

In all of its policy research and work with institutions, WRI tries to put ideas into action, meshing the insights of scientific research, economic and institutional analyses, and practical experience with the need for open and participatory decision-making.

For further information contact WRI at: World Resources Institute, 10 G Street NE, Washington, DC 2002, www.wri.org.

DONNA WISE *USA*

WTO (World Trade Organization)

The WTO created on 1st January 1995, is the institutional body established as a result of the successful completion of the Uruguay Round of multilateral trade negotiations. The WTO is an intergovernmental organization, succeeding and incorporating the framework of the General Agreement on Tariffs and Trade (GATT).

The central mandate of the WTO is trade liberalization. To that end, it incorporates key trade liberalization principles such as most-favored nation, national treatment and non-discrimination, provisions constraining the use of various trade restrictions and distortions (such as tariffs, quotas, subsidies, non-tariff measures and other trade instruments), and the general exceptions clause (GATT Article XX), which allows members to deviate from WTO obligations in pursuit of several public policy goals, including the protection of plant, animal or health life, or the conservation of exhaustible natural resources. WTO obligations are supported by binding international dispute settlement procedures, which represent the most stringent dispute arbitration mechanisms in support of international law.

From the outset, the WTO has broad-based membership representing industrialized and developing countries, in addition to countries with economies in transition. As of November 2000, 140 countries were WTO members.

WTO rules set out rights and obligations among states covering trade in merchandise goods, including sectors that remained largely excluded from trade negotiations in the GATT (notably, agriculture and textiles). In addition, the WTO sets out rules covering both trade in services, as well as trade-related intellectual property rights. Among the emerging issues on the new trade agenda are competition policy and investment policy, and these may be part of future multilateral trade negotiations.

Since its creation, the WTO Committee on Trade and Environment has examined links between trade rules and environmental policy. Three main clusters continue to be examined: the relationship between multilateral environmental agreements and trade rules; market access issues arising from environmental standards; and the role of civic society in trade policy. A number of WTO Dispute Settlement Panel and Appellate Body reports have involved environmental, human safety and food safety-related issues. The fact that the WTO finds itself arbitrating public policy issues traditionally outside of trade policy, coupled with a perceived lack of transparency and public accountability, have prompted concerns among the public about the mandate and capacity of the WTO to address international environmental issues. The implications of the WTO on environmental policy and environmental quality were the subject of public protests during the 1999 WTO Ministerial Meeting, held in Seattle, Washington.

More information on WTO can be obtained by contacting the WTO Secretariat, Rue de Lausanne 154, CH-1211 Geneva 21, Switzerland or at www.wto.org.

SCOTT VAUGHAN *Canada*

WWF (World Wide Fund for Nature)

The WWF is a leading independent conservation organization headquartered in Switzerland, with National Organizations in 26 countries and associates in five countries. Founded in 1962, it was originally known as the World Wildlife Fund and retains this name in Canada and the United States of America. It has 4.7 million supporters and 22 program offices in countries where it is focusing its activities. Its ultimate goal is To stop, and eventually reverse, the accelerating degradation of our planet's natural environment and to help build a future in which humans live in harmony with nature . WWF combines practical, solution-oriented field projects with education, capacity building and policy work. It seeks to demonstrate what can be done to address conservation problems, and then to help others acquire the necessary knowledge and skills to carry out long-term conservation for themselves. Through its policy work, WWF helps create the laws and agreements needed to conserve biodiversity. WWF's national organizations carry out conservation activities in their own countries and contribute technical expertise and funding to WWF's International Conservation Programme. The WWF network invests well over US$ 200 million per year in its conservation activities in some 100 countries, with most of its income coming from personal donations. Roughly half is used for domestic conservation by WWF National Organizations and half by the International Conservation Programme. WWF has recently developed a new approach to conservation, identifying 200 ecoregions that are critical to the conservation of the world's biological diversity, and seeks to focus its activities in these regions. Its Forest Programme seeks to halt the loss and degradation of forests and all kinds of woodlands, particularly old growth forests, and to establish a network of protected areas encompassing 330 million hectares that will include at least 10% of each of the world's major forest types. Its Oceans Programme seeks to create incentives for sustainable fishing, to reduce or eliminate destructive fishing practices and the by-catch of marine wildlife, and to establish effective recovery plans for key species of threatened marine fishes. The website for WWF is http://www.wwf.org.

Case Studies

Regional Responses to Global Environmental Change

Osama A El-Kholy
Arabian Gulf University, Manama, Bahrain

This contribution sets the stage for a series of essays on regional responses to global environmental change. It distinguishes between two major groups of global change: the systemic and the cumulative. Systemic global change requires worldwide responses, while cumulative global change must be dealt with by regional responses. Furthermore, in reviewing the case studies that follow, we need to bear in mind the differences between responding regionally to problems of conserving and sharing of natural resources, and addressing problems of regional environmental pollution.

PROBLEMS AND SOLUTIONS

A number of environmental problems are arising that require tackling global change on a multinational scale. To start with, is there a known solution to the problem? If there is, can it be implemented at acceptable financial and social costs? How long does it take to implement it? How urgent is it to act? And finally, how can the socio-economic burden be equitably shared by all the parties involved, given their different contributions to the problem and their abilities to bear the cost of remedial action?

Two things have become clear. Global problems cannot be solved without the active participation of all countries, developing and industrialized. To be effective, remedial action should be based on the precautionary principle. We need to act on the basis of scientific evidence, rather than on direct unambiguous observation of global change. If we wait that long, the damage may become irreversible.

These are the questions that have shaped, and continue to shape, responses to global change.

TWO TYPES OF GLOBAL CHANGE

Manifestations of global change fall under one of two major categories: the systemic and the cumulative. Systemic changes cover the whole globe, even though their impacts vary from place to place. Depletion of the stratospheric ozone layer, and global climate change due to global warming are well known examples of global systemic change.

Cumulative global changes, however, start on a local scale affecting specific areas. As these changes proliferate, they gradually acquire global dimensions. Examples are the various forms of land degradation, freshwater shortage, air and marine pollution.

SYSTEMIC CHANGES CALL FOR GLOBAL RESPONSES

Responses to systemic global change cannot be described meaningfully on a strict delineation of regions, geographical or political. The fact is that a number of countries from different regions have played prominent roles in building common multinational responses that cut across geographic and political boundaries. Common responses have sometimes come from countries that are widely separated geographically. This has happened both within developing, as well as amongst industrialized, countries, and even across this duality of grouping.

The three most important manifestations of systemic global change that have elicited global responses so far (stratospheric ozone layer depletion, loss of biodiversity and climate change) provide interesting examples of differences in our experience in responding to systemic change. The first was a pioneering exercise in formulating a global response to systemic change. It provided a prototype model for tackling such problems. The new approaches and mechanisms devised in this case were copied in addressing other phenomena of systemic change on a global scale later on. The second looked at first as if it had created a new balance of power between the industrialized and the developing countries. The third dealt with a problem that was shrouded in more scientific uncertainly than usual, while at the same time calling for solutions that are too drastic socially and economically to implement.

REGIONAL RESPONSES TO CUMULATIVE GLOBAL CHANGE

In the case of cumulative global change, the local manifestation of such change is primarily the concern of the countries in the locality of change. It is here that regional responses are well defined. They re ect the regional understanding of the problem, as well as the level and experience of cooperation in dealing with regional problems. This is obviously conditioned by the political climate in the region, the balance of power between the countries involved, and sometimes even the attitude of powerful players from outside the region.

The case studies of regional responses to global change highlight two major types, as outlined next.

TWO TYPES OF CUMULATIVE CHANGE

One major consideration that defines how certain factors shape the regional response is the nature of the cumulative

change problem; whether it concerns the conservation and sharing of natural resources, or addresses environmental protection. Examples of the first are the regional initiatives for the basins of the Zambezi and the Danube rivers, Lake Chad, and the Mekong delta. Examples of the second are the United Nations Environment Program (UNEP) regional seas program, the North African Green Belt and the European Air Pollution projects.

Strictly speaking, pollution abatement on a regional scale has a direct impact on natural resources, whether they come from land, waterways, or open seas. However, it also has more direct and significant benefits to human health and well-being. The planning and implementation of regional responses to pollution problems face the countries in a region with a situation different from that of projects for the sustainable development of shared natural resources.

SUSTAINABLE DEVELOPMENT OF SHARED NATURAL RESOURCES

As might be expected, projects for the conservation, sustainable development and equitable sharing of common natural resources raise highly sensitive political issues. They usually come up against practices that have been in place for considerable periods of time and that were established under very different political climates from those currently prevailing. The rational utilization and equitable sharing of common resources in particular presents sometimes highly complex challenges that render it difficult to achieve common regional responses. An international treaty providing a framework for dealing with this particular problem recently drafted in a United Nations (UN) conference (the UN Treaty on Non-navigational Uses of International Waters) was not accepted by some of the major player countries in some of the world's major river basins.

Conservation of marine resources in some areas has also resulted in disputes, even within reasonably well-established regional set-ups, such as the European Union (Spanish boats fishing off the British coast). The problem becomes more complicated when the dispute draws in countries that are outside the region, as in the case of the disputes between the European Union and Canada or Spain and two Maghreb countries (Morocco and Mauritania).

REGIONAL RESPONSES TO THE POLLUTION OF AIR, LAND AND WATER

In joint regional efforts to manage the pollution of one or more of air, land, water, certain conditions have to be satisfied. First there needs to be a reliable regional monitoring system to determine the type and scale of pollution, its geographic distribution, and its sources. When reasonably well-developed national monitoring systems exist, the task becomes that of integrating these into one coherent regional system. The situation is more difficult and costly when such a monitoring system has to be established almost from scratch. This has to be followed by an environmental assessment of the impacts on the different environmental media. Next, the nature and cost of optimum remedial action needs to be worked out. Assuming that these are also known, the equitable sharing of costs is the next step. This is perhaps the most difficult stage in working out a regional program for environmental protection. Finally, there is need for periodic reviews of the issue in the light of changing global and local conditions: the so-called *adaptive assessment process*.

Perhaps one of the more successful examples is the European effort to control air pollution across the continent, initiated by the UN Economic Commission for Europe. There are also two cases of dealing with land-based sources of marine pollution (the Black Sea and the Mediterranean), where an outline action plan has been worked out; but funding for its implementation has yet to be obtained. Several other examples exist in combating desertification in some regions.

It can, however, be said in conclusion that responding to global change on a regional basis is gathering momentum and gradually engaging the attention of decision-makers. While the industrialized countries are ahead in this process, developing countries are moving in the same direction with help from donor countries and inter-governmental organizations.

This contribution sets the stage for selected case studies on regional responses to regional stresses in the context of global change. (It is not possible to provide more than a sampling of such studies in this volume.)

These case studies have been brought together following this introduction at the end of Volume 3 – see Table of Contents for Volume 3 for a detailed listing.

Seas

Baltic Sea

Bengt-Owe Jansson
Stockholm University, Stockholm, Sweden

The semi-enclosed Baltic Sea is a poor receiving area for the wastes of the increasing human population in the large watershed. Nutrients and toxic substances from land runoff and atmospheric fallout create turbid waters, dead bottoms and decline of fish-eating birds and mammals. Nine countries with different policies and stage of development make strong measures of redevelopment difficult to take. Still, success stories of recovering birds and seals, thanks to the development of institutional tools and citizen involvement, give hope for the restoration of ecosystem health.

This semi-enclosed sea is surrounded by nine countries with a total population within the watershed of ca 90 million (Figure 1). It is geologically young, having passed four stages: the Baltic-Ice Lake, the Yoldia Sea, the Ancylus Lake and the Littorina Sea, alternating between fresh and saltwater since the recession of the last glaciation 10 500 years ago. Its mean depth is 55 m (Table 1) and the narrow connections to the North Sea are shallow, restricting the total water exchange to 25 years. The freshwater runoff from numerous rivers in the drainage area generates an inflow of the salty water from the North Sea, creating a gradient of the surface salinity from ca 10 parts per thousand (ppt) inside the entrance to nearly freshwater in the northern Gulf of Bothnia. The surface water temperatures show a similar gradient northwards with fast ice cover during 60% of the year in the northernmost part. The sills create a vertical stratification of the brackish water with a stable halocline at 50–70 m depth, between a low salinity surface layer, slowly moving out of the Baltic, and a saltier, and therefore heavier bottom water flowing inwards along the eastern side of the basin due to the earth's rotation. Due to the minimal tidal movements, the stratification of the water makes the Baltic deep water very sensitive to processes that consume oxygen (O_2), like decomposition of organic material of dead plants and animals settling on the bottom. The decomposing bacteria assembly also contains hydrogen sulfide-producing species, the deeper parts of the Baltic Proper alternating between oxic conditions with higher animals like worms, crustaceans and clams, and periods of hydrogen sulfide dominated by billions of sulfur bacteria. Denitrifying bacteria during periods of low O_2 convert nitrogen (N) in the sediment to nitrogen gas, which leaves the sea for the atmosphere. This process may export half of the annually deposited nitrogen load in the Baltic. An important renewal mechanism for the bottom water is large pulses of North Sea water, rich in salt and O_2, caused by prolonged periods of westerly gales which transport water in the order of tens of km^3 into the Baltic basin. In between, stagnant conditions with low O_2 and hydrogen sulfide may dominate for decades (Figure 2, map) These unpredictable events are responsible both for maintaining the salinity of the whole Baltic and for the amount of economically important fish (Figure 2c).

The organism assembly in the Baltic is a mixture of hardy saltwater and freshwater species, immigrating from ocean and freshwater, and therefore not adapted to the adverse conditions found in the Baltic. Of the 1500 animal species seen with the naked eye off the southern coast of Norway, some 50 are left in the Baltic at the latitude of Stockholm. This means that the number of species performing the basic processes of an ecosystem like fixing solar energy, decomposing dead organic mater, and filtering water, is small and a decrease in species diversity due to stressing environmental conditions will restrict the production capacity of the system. Still, the Baltic has worked well when undisturbed. Cod and flounder can be caught in the same gill net as pike and perch and the species of plants and animals are found in large individual numbers although usually of smaller body sizes. At optimal conditions, the fisheries have landed close to 1 million tons of fish per year, mainly herring, sprat and cod. This is 1% of the world catch from a sea 1 per mille of the surface of the world ocean (Figure 2a).

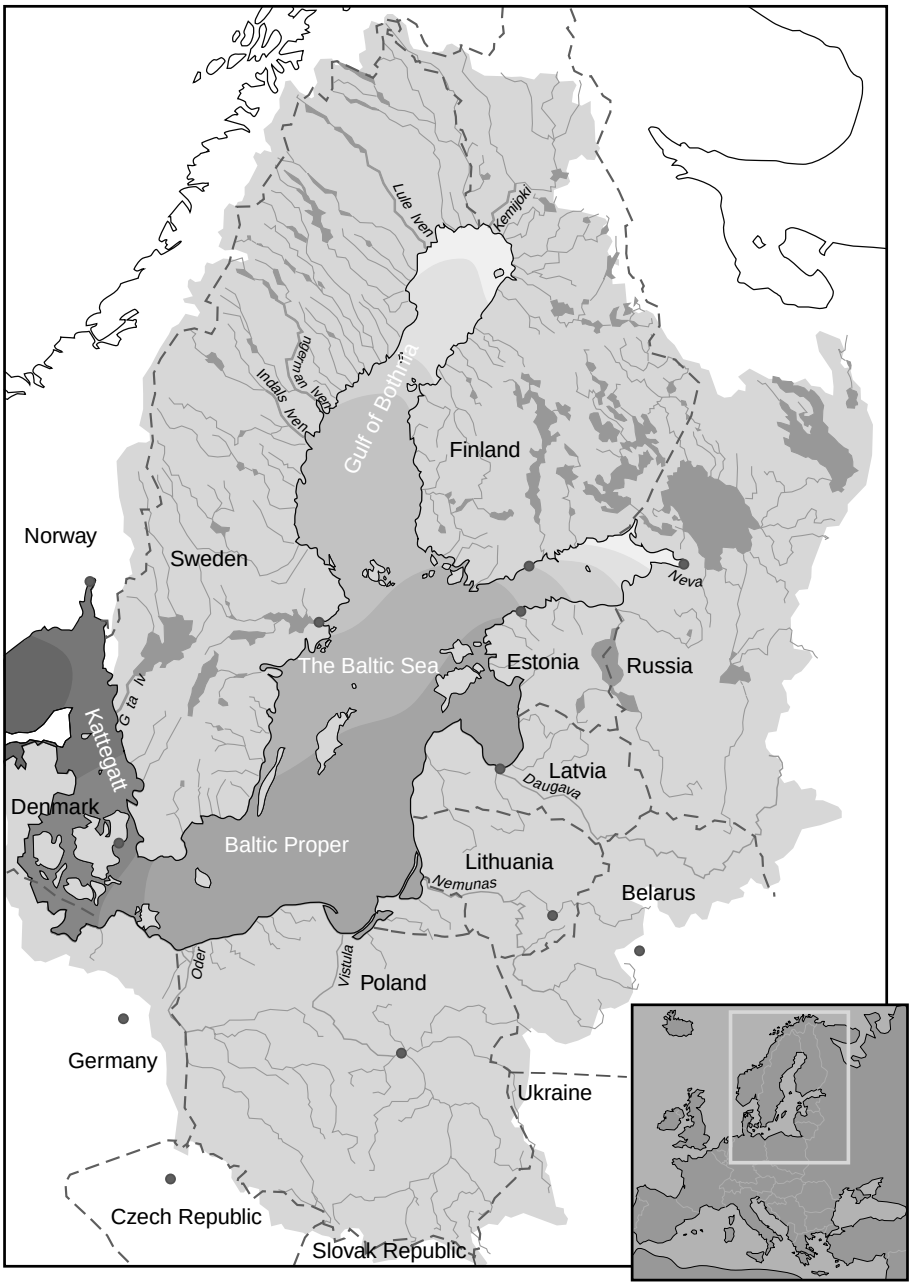

Figure 1 A map of the Baltic Sea

A typical Baltic habitat is the rocky archipelagos of the Swedish east coast and the Finnish west coast. Tens of thousands of islands and islets, with bottoms covered with the brown seaweed bladder wrack or *Fucus*, the blue mussel *Mytilus*, and during the summer green and brown filamentous algae form important spawning and nursery areas for fish. The great potential for sports fishing and boating and the beauty of the scenery have made these areas of the Baltic targets for an increasing tourist industry and summer residence for the coastal urban human population.

Some of the economically important fish like herring need the coastal areas for spawning but spend most of their time in the open waters, feeding on the pelagic food web. Based on solar energy and nitrogen and phosphorus (P) in the water, the microscopic plants show several blooms during the summer half of the year, among them a conspicuous, toxic bloom of cyanobacteria at the end of summer, taking its nitrogen from the atmosphere. This is nature's way of solving a lack of nitrogen due to consumption by previous algal blooms. The settling of dead plants and animals on the sea oor forms both

habitat and food for the bottom animals like crustaceans and the Baltic clam, *Macoma*, important food for the bottom fish.

The southern coasts of the Baltic Sea consist of transported sand and silt from the receding inland ice. Poland and the eastern Baltic states have good soil for agriculture, compared to the northern part of the Baltic drainage basin, dominated by forests and forestry. Since the 19th century, the population of the Baltic basin has increased four times and the use of fossil energy about 30 times. The urban centers, especially around the coasts, have expanded, and act as large consumers of energy and material, exporting large amount of wastes to sea and atmosphere. The emissions of phosphorus and nitrogen from agriculture, the transport sector and industry have, since 1900, increased eight and four times, respectively (Figure 2e). The increased consumption of O_2 of the deeper bottom waters due to increased primary production have caused extended periods of hydrogen sulfide. Decreased water transparency by 2–3 m since the 1910s has reduced the areas of *Fucus* vegetation because of less light. In the shallow parts of the sea, the amount of fish food of worms, crustaceans and clams has increased, and good food also in the open waters has favored the growth of pelagic fish like herring and sprat. Cod, spawning in deeper water, suffers from the stagnation periods (Figure 2c) and is, like the other species, overfished. Toxic substances from industry and agriculture have accumulated in the upper parts of the food chain, e.g., seals and fish-eating birds. The persistent polychlorinated hydrocarbons like polychlorinated biphenyls (PCBs) and dichlorodiphenyltrichloroethane (DDT) brought seals and sea eagles close to extinction during the 1970s (Figure 2b).

The suite of environmental incidents: the mercury crisis during the 1960s, the DDT and PCB problems during the 1970–1980s, and the increasing eutrophication of the coastal waters, escalated public pressure on existing responsible institutions. Theoretically it led to an increase of the resilience of the total Baltic system by developing institutions at different levels to prepare the system for environmental crises. One of the main catalysts for this process was the International Stockholm Conference on the Environment 1972. Among the lobbyists behind the conference were two informal organizations: the Baltic Oceanographers and the Baltic Marine Biologists, both with biannual conferences and workshops for standardizing methods, planning field studies and exchanging data. The critical state of the Baltic Sea discussed at the Stockholm Conference initiated the Convention on the Protection of the Marine Environment of the Baltic Sea, signed by the Baltic states in Helsinki, Finland in 1974. It is the first convention of its kind, including detailed prescriptions on how to combat pollution of all kinds in a multinational, marine area. Its commission, the Helsinki Commission (HELCOM), got an extended mandate in 1992, through including nature conservation and coastal zone management, already mentioned in a ministerial declaration of 1988. There, the seven states also announced a 50% reduction of the main pollutants to be achieved by 1995. At a prime ministerial conference in Sweden in 1990, a Baltic Sea Declaration was adopted, implemented by a task force within HELCOM to an action-oriented program – Joint Comprehensive Program. The investment priorities were based on effects on human health, ecology and economic feasibility. The most cost-effective hot spots have been identified, and of the 132 locations nearly two-thirds are located in the Eastern countries. In 1991–1992 the estimated costs amounted to 18 billion ECU over a 20-year period. The goal set in the ministerial declaration of 1988 has not yet been reached, however.

Table 1 Oceanographic data of the Baltic Sea. (For fuller description see Voipio, 1981)

Statistics	Measure
Area, total km^2	415 000
Area, Baltic Proper km^2	267 000
Length (N–S) km	1300
Width (W–E) km	1200
Average depth (m)	55
Maximum depth (m)	459
Sill depth (m)	17
Volume (km^3)	21 700
Residence time of water (years)	25
Tides (cm)	2–3
Total drainage area (km^2)	1 641 650

A regional Agenda 21 for the Baltic Sea Region (Baltic 21) was adopted by the environmental ministers in 1996. It comprises goals, scenarios and action programs for sustainable development for seven sectors: agriculture, energy, fisheries, forestry, industry, tourism and transport. The work shared by the different countries was completed in 1999.

HELCOM is the basic institutional instrument for governing the *natural capital* (*see* Natural Capital, Volume 2) of the Baltic Sea. It also comprises non-governmental organizations (NGOs). Individually, or through NGOs, the people have activated existing organizations and forced the birth of new ones because of their wish for clear water, pure food and clean air. During the Soviet era, environmental action was checked in the eastern countries. The Nature Conservation Society in Estonia was established in 1966 as the first one in Soviet Union. Like the Ecological Club in Poland a decade later, it demonstrated the bad state of the environment and fought for democracy. The environmental movement in the eastern countries played an important role in starting the transition process. Also, the World Wildlife Federation

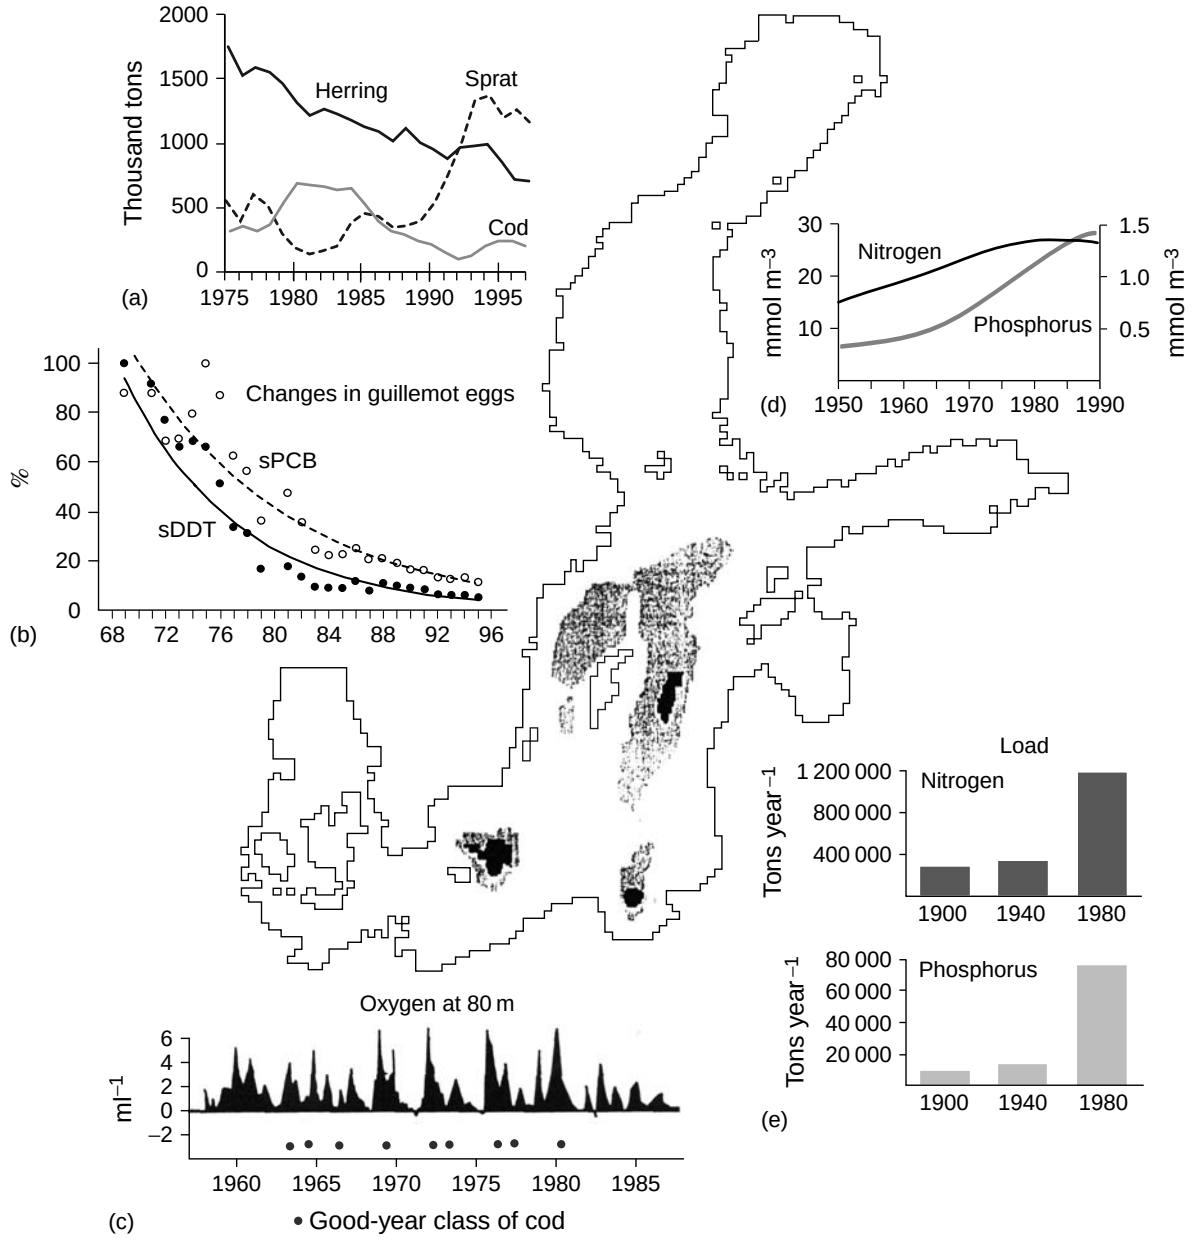

Figure 2 The changing Baltic Sea. Map in the middle of the figure shows the O_2 conditions of the bottom water in August 1998, gray shading corresponding to bottom areas with less than 2 ml l^{-1}, black areas with hydrogen sulfide (F Wulff, personal communication). (a) Trends of spawning stocks of main commercial fish species (ICES, 1998). (b) Concentrations of DDT and PCB in egg yolk of alks from central Baltic compared to levels in 1968 (Bignert, 1997). (c) O_2 content in main cod spawning areas compared to good year classes (Bernes, 1989). (d) Trends of nitrogen and phosphorus concentrations in open Baltic waters (computer simulations by F Wulff, personal communication). (e) Total annual load (input) of nutrients to the Baltic Proper since 1900 (Jansson and Dahlberg, 1999)

and Greenpeace International are active, and during the 1990s the Swedish Society of Nature Conservation and its Finnish counterpart created an umbrella organization for the many NGOs in the region – the Coalition Clean Baltic. Several of the organizations have observer status in governmental boards and management organizations and constitute important bridges between the public and the policy makers by increasing the spatial distribution of interactions.

The Lake Peipus Project is a good example of what citizens' stamina and hard work can achieve. This lake, fourth in size in Europe, is now shared by Estonia and Russia. Before the transition, the area was supported by Soviet Union as an important producer of high-quality

fish and agricultural products. When this market collapsed, people, especially on the Russian side, suffered, agriculture and management of the fishery sources declined, and water quality decreased. Thanks to a few concerned and idealistic people in the area, a transboundary commission was created, monitoring was restarted and participatory planning of the common resource use was developed by attracting foreign capital. A new future seems to be opening up through tourism, based on the pristine nature of the area.

The effects of the liberation of the occupied Eastern countries are far reaching, as environmental problems are regional, integrated and long-term. In 1994, the ministries for spatial planning formulated a framework for spatial planning in the Baltic Region: Vision and Strategies around the Baltic Sea 2010. The goal is to develop a strong infrastructure based on combinations of railways and roads, linking peripheral and central areas. West–East exchanges are especially considered.

Although the environmental goals have not been reached, nutrient concentrations in the open waters have leveled off since the mid-1980s (Figure 2d). This is probably due to the recession in economic development in Poland and the eastern countries. Due to bans in the mid-1970s, the levels of PCB and DDT in eggs of fish-eating birds and in gray seals are now down to 10 and 5% of 1968 levels, respectively, and the northern gray seal population is rapidly recovering (Figure 2b). Growing problems are the expanding urban centers, however, needing products and services of the surrounding ecosystem: freshwater, food, material, and processing of wastes. Calculated on an area basis, quantifying the ecological footprint in the late 1990s, the 29 biggest cities use 75–150% of the total Baltic Basin area.

The present environmental status of the Baltic Sea is probably close to the border between that of a less productive and healthy stability domain. These should include a clear reduction in the human resource use in the western countries, in order to create a more sustainable Baltic Sea area.

A description of the changing conditions of the Baltic Sea is found in Jansson and Dahlberg (1999).

Black Sea

Henri J Dumont
Ghent University, Ghent, Belgium

The surface area of the Black Sea is ca 423 000 km^2, and its volume 547 000 km^3. Maximum depth is 2212 m. The abyssal zone is situated in the south and is distinctly east- west oriented (Figure 1), while extensive shallow shelves (less than 200 m deep) occur in the north. The sea is currently a net exporter of water towards the Mediterranean, with the surface out ow about twice the deep and more salty in ow (about 130 km^3 year^{-1} ow in, against about 300 km^3 year^{-1} owing out, according to one conservative estimate). This excess is due to the contribution of a few major rivers, with the Danube (ca 210 km^3 year^{-1}) particularly prominent, followed by the Dnepr (50 km^3 year^{-1}). The in ow through the Strait of Kerch, mainly composed of water of the Don and Kuban rivers, varies from 20- 95 km^3 year^{-1}). All major rivers empty in the shallow northern zone, causing a salinity gradient from north to south. This northern, fresher water may freeze in winter, while the more saline water in the south does not. At least as important is a vertical gradient in water chemistry. The heavier salt water of Mediterranean origin sinks to great depths and does not mix with the overlying lighter surface water. This produces a gradient in salinity, with total salinity at the surface (0- 300 m) 17- 21 mille^{-1}, and below that ca 22 mille^{-1}. Because of the lack of exchange between layers, nutrients and other compounds sinking out to the bottom are lost to the dynamics of the surface ecosystem. Moreover, the deep layers have become totally depleted in oxygen. Only reduced compounds (e.g., H_2S) occur there (see Figure 2), and, as a result, more than 80% of the volume of the Black Sea is virtually devoid of eukaryotic plant and animal life.

BRIEF GEOLOGICAL HISTORY OF THE BASIN

The contemporary Black Sea, including the Sea of Azov, is currently a true hybrid between a sea and a lake. However, it was a brackish-water lake for most of its existence. Like the (south) Caspian, it is a remnant of the Tethys Sea, which gradually became isolated from the

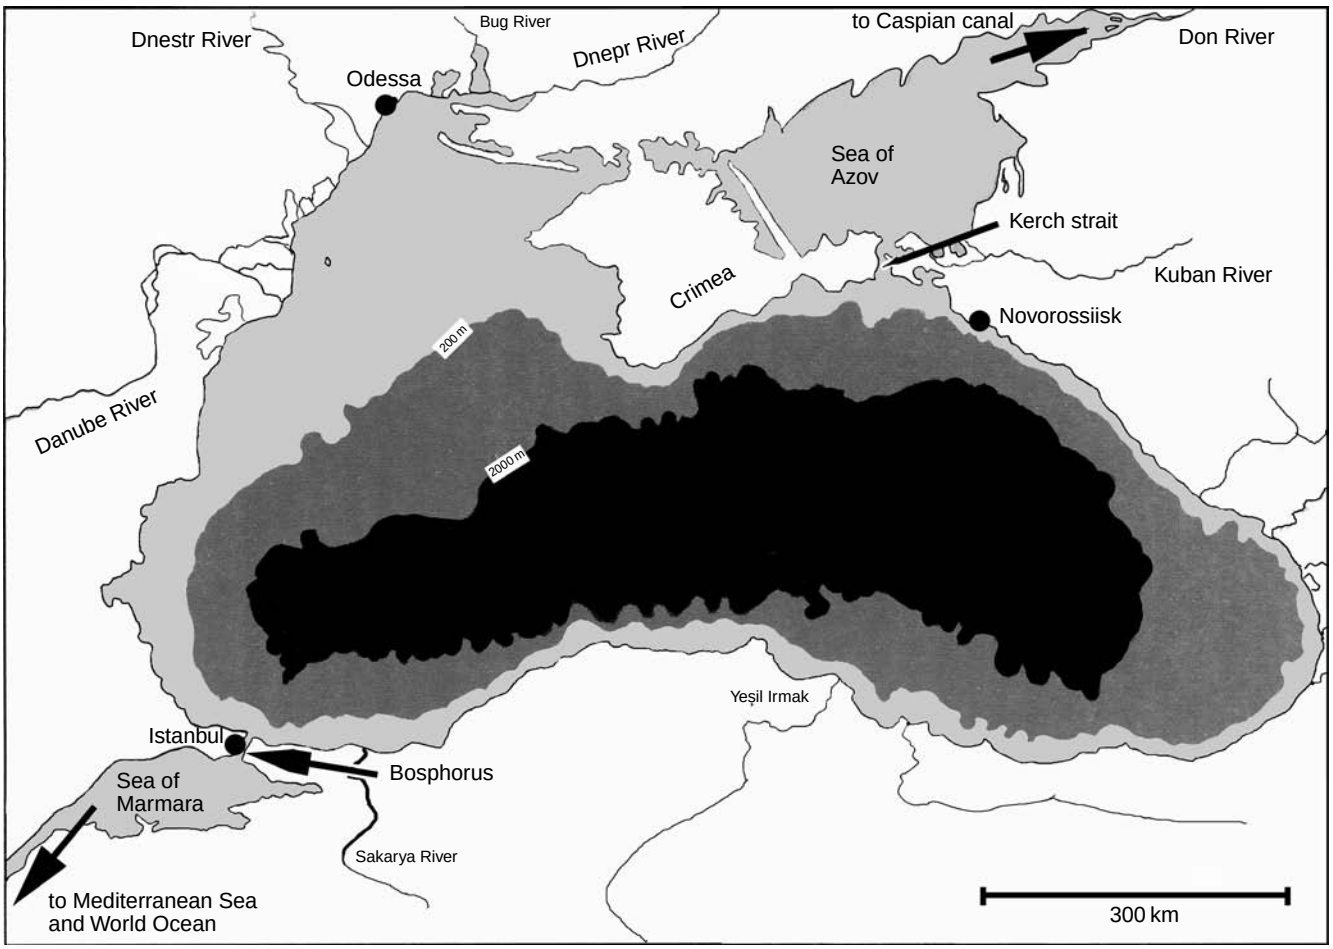

Figure 1 Map of the Black Sea, with major bathymetric divisions and major tributaries indicated

World Ocean as the Miocene orogenesis uplifted the Alps, Carpathians, Pontic, Balkan and Caucasus mountains. There has been no connection with the ocean from the Pliocene onwards (at least 3×10^6 years BP) until the mid-Holocene (ca 7000 BP, possibly even as recently as 5000 BP), save for an interval during the Riss-Wurm interglacial, some $1{\bullet}5-1 \times 10^5$ years BP.

Throughout the Pleistocene, there was a complex suite of recessions and high levels, corresponding with glacial/deglaciation cycles. The Black Sea and the Mediterranean were not connected, however, and the Black Sea uctuated between saline and almost fresh conditions. Around the mid-Holocene, when the Mediterranean broke through the Bosphorus, it stood over 100 m below its present level. The opening of the Bosphorus had dramatic effects: the entire north-west shelf and Sea of Azov were ooded at a rate that probably outpaced that of a walking person (see Figure 1: the ooded zone was not much smaller than that currently below 200 m in depth). Due to the fact that this at area was likely rather densely populated, and possibly a site of early agriculture and domestication of cattle, the ood event was remembered in legends and myths, like the Gilgamesj epos. It was also recorded in history as the Biblical ood.

BIOLOGICAL DIVERSITY

The original biota of the Black Sea were shared with the Caspian Lake, and included large numbers of locally evolved crustaceans. Some of these endemics still survive, but many of them have been pushed back to the estuaries and coastal wetlands or limans, where salinity is low enough to suit their osmotic requirements. The entering Mediterranean water raised the salinity of the open water zone sufficiently to allow a large number of marine species and groups to successfully colonise the Black Sea. These include algae, and animals from protozoans and cnidarians to marine mammals such as dolphins and seals. Many truly marine species are still incapable of adjusting to the salinity of the Black Sea, however, and as a result, the species richness of the sea is only between 0 and 50% of that of the Mediterranean, depending on the group considered. The

deep hypoxic zone furthermore limits the number of species to those that can live in the littoral and in the surface layers of the pelagic.

In spite of this impoverished assemblage, many species became quite abundant and exploitable. Such is, or was, the case of numerous fish, mollusks (mussels, oysters), and of the sessile seaweeds *Cystoseira* (a brown alga) and *Phyllophora* (a red alga) that covered a surface area of thousands of km^2 until the 1960s, when they were heavily exploited as a source of agar.

DECLINE AFTER 1950

The history of the biota of the Black Sea after 1950 is invariably one of decline, due to eutrophication by nutrient-loaded surface and river runoff, overharvesting, introduction of alien species, and a combination of these, with an acceleration since the 1970s. A specific threat is intense shipping activity, including the traffic of crude oil from the harbour of Novorossiisk, endpoint of the Caspian oil pipeline, to the world market via the Bosphorus where at least one major accident occurred in the 1990s.

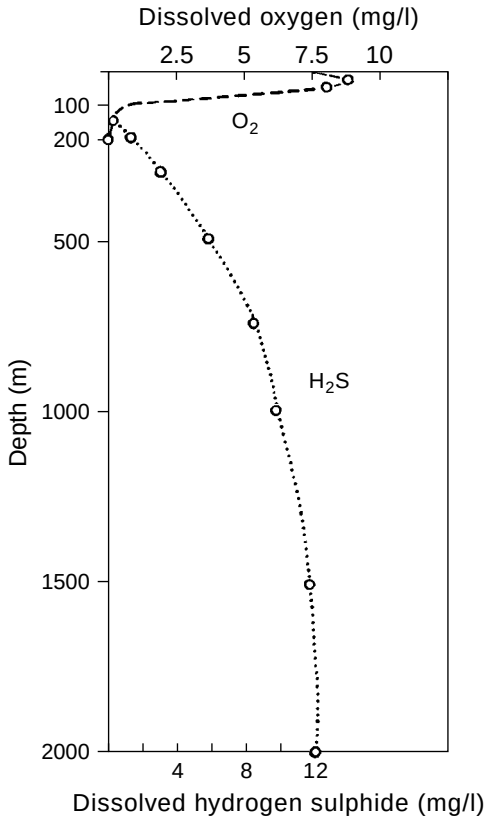

Figure 2 Vertical profile of dissolved oxygen (dashed line) and of hydrogen sulphide (dotted line) in the Black Sea. Both gases are mutually exclusive, and indicate the depth to which the water masses mix (modified from Mandych *et al.*, 1995). (Reproduced with permission of Backhuys Publishers, Leiden, The Netherlands)

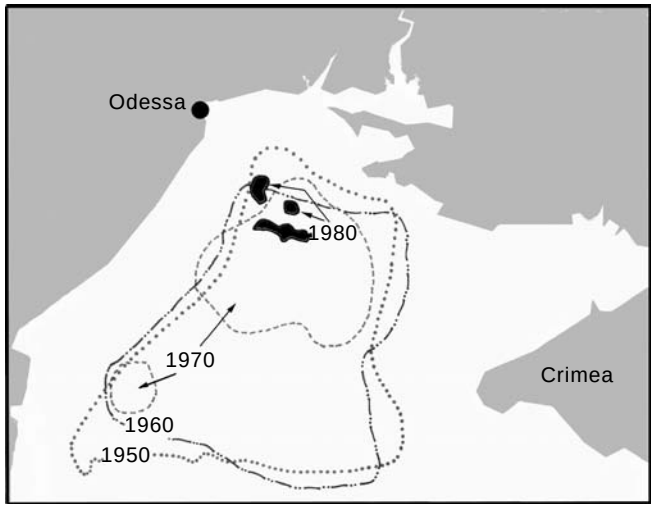

Figure 3 An example of the environmental degradation of the Black Sea and its biota: progressive reduction of the *Phyllophora* fields after 1950 (modified from Zaitsev and Mamaev, 1997). (Reproduced with permission of UN Publications, New York)

All biota have decreased, but the trend has been particularly spectacular in the north, where the enormous *Cystoseira* and *Phyllophora* algae-fields have shrunk to the point of almost complete annihilation (Figure 3). These algae were true keystone species, providing food and shelter to a complex community, ranging from protists to fish, and all these species declined or disappeared along with the algae. Eutrophication, progressive bottom deoxygenation encroaching the shelf areas since the 1970s, and stirring up of sediment by trawl fishing have all accelerated their demise.

Overfishing, in its turn, has caused the collapse of the populations of several pelagic fish like tuna, mackerel, swordfish and others, although in certain cases, the destruction of spawning grounds (sometimes situated in the Mediterranean) also contributed. The fisheries gradually shifted towards smaller species such as anchovy and sprat but these, in their turn, collapsed after the introduction – presumably with ballast water from the east coast of North America – of the fist-sized comb jelly *Mnemiopsis leidyi*, a voracious carnivore. This introduction may have occurred in the late 1970s, and was first spotted in 1982. By 1988, a fresh-weight biomass of 1×10^9 tons had developed, which wiped the sea clean of zooplankton, pelagic fish eggs, and fish larvae. Pelagic fisheries dropped by at least an order of magnitude and a large part of the fishing eet went out of business. Numerous other unintentional introductions took place, but none was so destructive as that of *Mnemiopsis*. After 1988, a relative decline occurred, perhaps due to shortage of prey, or an increase in *Beroe*,

another ctenophore, and one that preys on *Mnemiopsis* itself. The introduction of milkfish, a natural predator of *Mnemiopsis* in its natural range along the coasts of the east Atlantic, has also been proposed. In addition to containing the intruder, it might itself develop into an exploitable resource.

ACTIONS

The regional political situation was not conducive to coordinated action between the six littoral countries until the 1980s. It was therefore not until the deployment of large-scale, international initiatives in favour of the environment, that serious attempts at addressing the pressing problems of the Black Sea were undertaken. The Global Environmental Facility (GEF) of the United Nations (UN) launched the Black Sea Environmental Program in 1993. As a result of the regional cooperation that thus developed, a Black Sea Action Plan (BSAP) was agreed at a ministerial conference in Istanbul in 1996, and a permanent Black Sea secretariat was set up. This project worked out detailed assessments of the state of valuable biological resources, and plans (including required budgets) for their restoration or conservation. Clearly, in addition to donor funding, a substantial effort by the littoral countries themselves will be needed; success or failure of the BSAP is therefore now in political hands. A similar GEF programme on the Danube River, the single most important contributor of nutrients, organic residues, and occasionally highly toxic compounds to the Black Sea, has been carried out in parallel. A third one deals with the Dnepr River. Pollution abatement along the Danube, including its upper reaches in Germany and Austria, will be needed to significantly improve the situation of the Black Sea. Because the Black Sea traps most chemicals in its anoxic monimolimnion after not more than 1 year, the effect of such measures should rapidly become visible. It is therefore to be expected that the future of the Black Sea as an ecosystem will be decided within the first decade of the new millennium.

Caspian Sea

Henri J Dumont
Ghent University, Ghent, Belgium

The Caspian Sea, the largest lake on earth, is situated east of the Caucasus and north of the Elburz mountains. It is the endorheic terminus of the Volga River, which forms a large delta at its at north end, and contributes more than 80% of its yearly in ow, 237 km^3 year^{-1} on average (range 200- 450 km^3). More than 100 other rivers contribute the remaining 20%, with only the Kura and Ural signi cant. Lake volume is c. 78 000 km^3 (about 40% of the world's continental surface water). Lake surface area, situated about 28 m below ocean level, is close to 400 000 km^2. The shape is elongated (c. 1500 km) and is almost perfectly north- south oriented, thus stretching from a continental to a Mediterranean climate type. In addition, there is a steep precipitation gradient between the wet western shores, and the desertic eastern shores. The lake is composed of three basins: a shallow, freshwater north basin, and two deep and brackish central and south basins (Figure 1). Salinity in the deep basins reaches 12- 14 mille^{-1}, except in the salt-pan of Karabogaz, which may completely dry out, and usually contains a saturated brine. It is exploited for salt and for brine shrimp. In contrast to the Black Sea, the lake is oxygenated to the bottom, but at times of high lake stands, when much freshwater ows in, vertical circulation may become compromised, and anoxic conditions may develop in the two deep basins.

GEOLOGICAL HISTORY

The lake formed in the Miocene when the Tethys sea closed, as India and the Arabian peninsula hit the Asian continent, pushing up major mountain chains, and creating a number of landlocked basins, including the Black Sea, the South and Middle Caspian troughs, and the Amu and Syr Darja Rivers.

From the very beginning, the Caspian was a brackish lake, but it shrank and expanded on numerous occasions, and its salinity uctuated accordingly, from a nearly saturated brine at low lake stands, to almost freshwater at high

stands. At high lake stands, contacts were established with the Black Sea and with the Aral lake.

IMPACTS

About half of the heavy industry of Russia is situated in the Volga valley, and its effluents, washed to the Caspian, cause toxic pollution and eutrophication, which was particularly strong in the delta and the shallow north during the 1980s. After the economic collapse of Russia, the situation greatly improved in the 1990s. Other impacts have a more local character, and consist of the effluents of major cities, which may have strong effects on water quality if they are discharged to semi-enclosed, shallow bays, such as that of Krasnovodsk (presently Turkmenbashi) (Figure 1). Sloppy exploitation of oil fields, whether on land or offshore, is also a major source of pollution, for example, along the Kazakh coast. The bay of Baku is an example of the combined impact of a major city (Baku), its oil fields, and the industrial sewage of the industrial complex of Sumgait. As a result, Baku Bay is said to be biologically dead.

Leakage of radioactive wastes through a limestone bottom to the lake has been claimed to occur near the Gur'evskaia nuclear power plant in the north east corner of the lake.

WATER LEVEL FLUCTUATIONS

The hydrological balance of this closed basin is determined by the algebraic sum of river inflow, direct precipitation, and evaporation (neglecting groundwater inflow). Dry years in the Volga basin should thus be reflected in a negative balance, and a falling lake level. Things are not that simple, however, and the actual relationship between Volga inflow and lake level is statistically weak. This indicates that evaporation is a major factor too. In fact, in historic times, there has been an alternation of maxima (around the -26 m level) and minima (around the -30 m mark). In the 20th century, one maximum occurred in the 1930s, and a second one in 1995, separated by a low in 1977. A major man-made impact, the construction of a series of reservoirs in the Volga basin, took place in the 1940–1960s, coinciding with a receding phase. Little effect of this damming was felt by the littoral population, and by the time the lake started rising again, the reservoirs were all full.

One of the striking features of the 1930–1977 recession was a loss of ecological memory: many old taboos on shoreland use were broken and, as the lake fell, various constructions, including heavy industry, were built on previously flooded grounds. In the post-1977 rise, problems of flooding arose. These were comparatively mild in Iran, but involved oil fields in Azerbaijan, Turkmenistan, and Kazakstan, and caused severe pollution problems along the Azeiri shores, where major deposits of toxic solid waste were washed out from the industrial zone of the city of Sumgait. Corrective actions have included polder and dike building, and the main lesson learnt is clearly that history repeats itself, and that certain coastal zones should not be developed.

BIOTA

Biologically, the lake shows a percentage endemism in its fauna and flora comparable to that of Lake Baikal, although its total species richness is only about half that of its Siberian counterpart. The biota of the Caspian have been selected for euryhalinity, a capacity to adapt to wide changes in salinity, and are probably derived from estuarine ancestors with a freshwater origin. True marine groups are absent.

Because of the conspicuous absence of marine groups, and in order to increase the number of harvestable products from the lake, Soviet scientists embarked on a program of species introductions – almost all marine – as early as the 1930s. Some of these acclimatisations were successful, others were not. In addition, the commissioning of a canal between the Volga and the Don opened the Caspian to maritime traffic, allowing direct contact with the ocean through the Black Sea. Via this route, a number of additional species (especially those capable of settling on a ship's hull) entered the Caspian (e.g., balanids), while others escaped to the outside world, eventually creating problems of mass development elsewhere. A case in point is the bivalved mollusk *Dreissena polymorpha*, which caused great economic loss in the Great Lakes of North America.

The current use (and abuse) of ballast water in shipping has added another hazard. In the Black Sea, a brackish-water comb jelly, *Mnemiopsis leidyi*, originally found in estuaries along the east coast of North America, was thus introduced in the 1980s. This voracious predator eliminated zooplankton and larval fish to a point where, in 1989, it had reached a wet biomass of 10^9 tons. As a result, the Black Sea pelagic fishery, already stressed by eutrophication, pollution, and overexploitation, collapsed. If this species were to successfully invade the Caspian, it might rapidly destroy the local sardine or kilka fisheries, with possible fatal repercussions for the kilka-eating top predator, the endemic caspian seal.

In 1996, the first reports of fishermen sighting strange jellies in their nets started circulating; in 1999, scuba divers off the Sjevsjenko peninsula brought in the first certified video images of *Mnemiopsis* in the Caspian. A population explosion, with biomasses of up to $0.5\,\mathrm{Kg\,m^{-2}}$ (wet weight), was reached in late summer 2000 (Ivanov *et al.*, 2000).

Another valuable product of the Caspian is caviar, the roe of the four local species of anadromous sturgeon fish. At

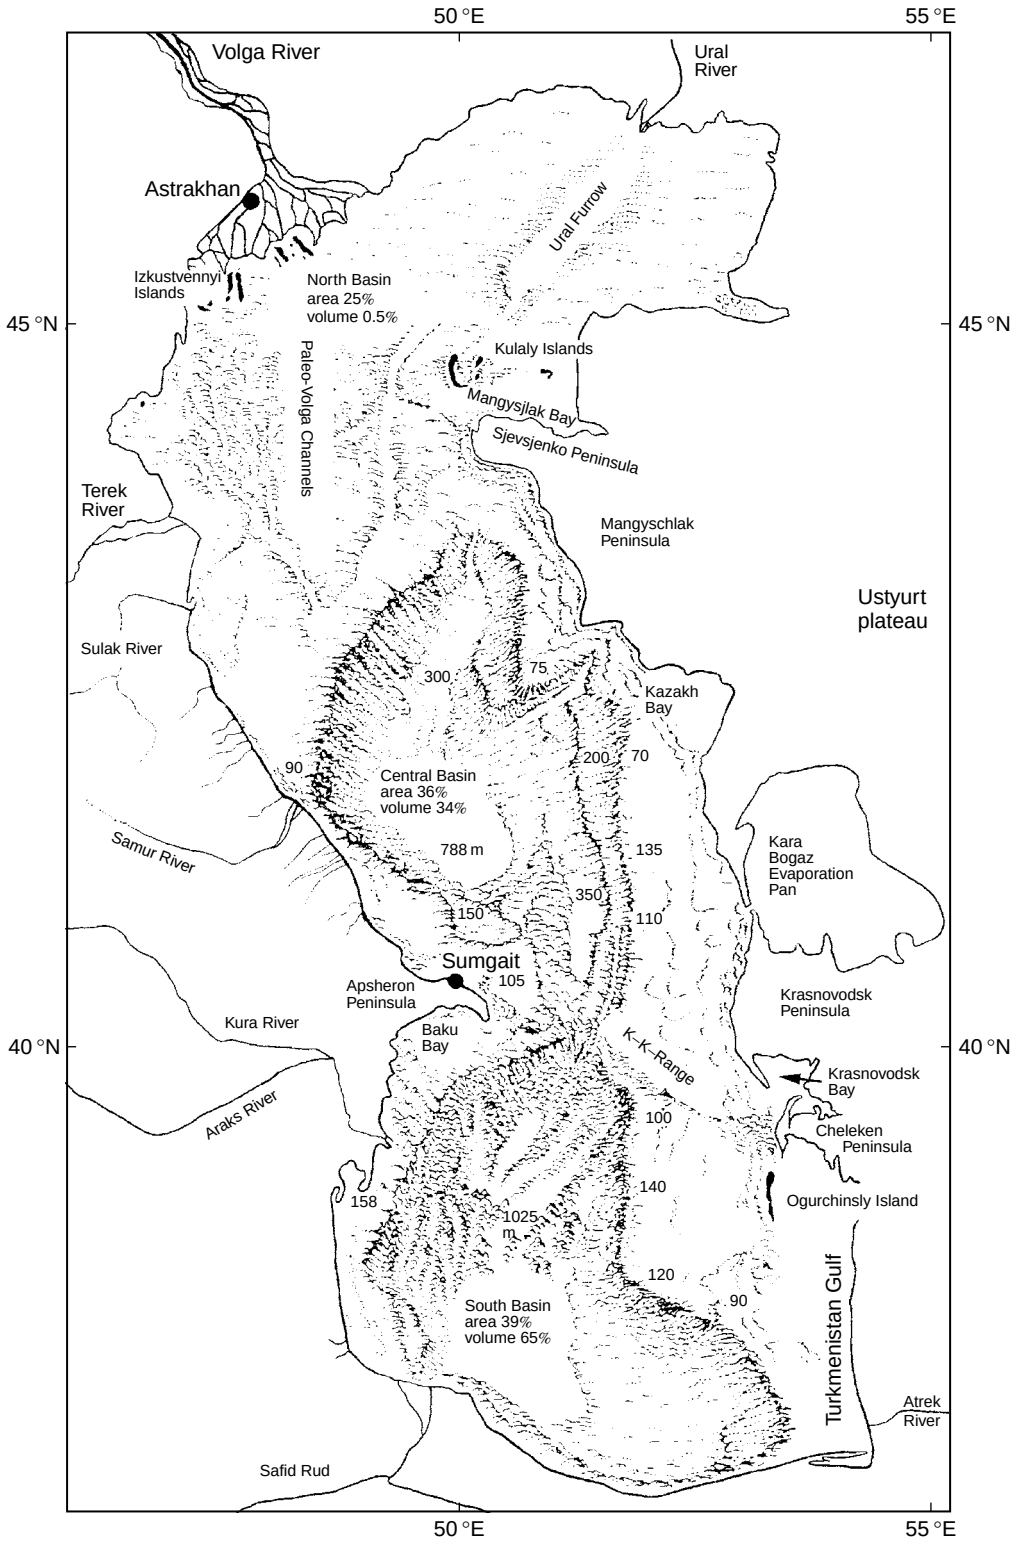

Figure 1 Map of the Caspian basin, identifying the major rivers, the three basins and their characteristics, and some localities cited in the text. The K–K range is a sub-lacustrine threshold that separates the central and south basins (Modified from Dumont, 1998 with permission)

certain times, over 90% of the world production of sturgeon was in the Caspian basin, with a peak of 39×10^3 tons in 1903. It should be noted that 7–10% of a female's body weight is caviar.

A first collapse of the fisheries occurred in the 1930s, because of simultaneous riverine and lacustrine fishing, destroying mature individuals migrating up the rivers (mainly the Volga) to spawn, and immatures in the lake. Legislation prohibiting pelagic fisheries resulted in a recovery after World War II. However, the damming of the Volga (and later of the Kura) soon caused a new problem: the spawning grounds of the sturgeon were ooded, and reduced to 12% of their original extent.

This situation, in its turn, was corrected by the construction of a series of sturgeon hatcheries in the surroundings of Astrakhan. The yearly release of fingerlings to the Volga reached a maximum of c. 100×10^6 specimens in the mid-1980s, but declined after the collapse of the Union of the Soviet Socialist Republics (USSR) because of inadequate funding and deterioration of the hatcheries. The collapse of the USSR also caused a beneficial decrease in the pollution levels of the Volga, which had caused massive muscle-tissue deterioration in sturgeon, peaking in 1987–1988, but there was an antagonistic increase in illegal fisheries, riverine as well as pelagic. As a result, the stocks of sturgeon began to decline once more. In the case of the largest sturgeon, the Beluga (*Huso huso*), declines are such (Figure 2) that extinction may be reached around 2003.

Attempts to revitalise the sturgeon aquaculture in the lower Volga by the World Bank and other international agencies have not, so far, produced tangible results, even though the technology for rearing sturgeon to adulthood is well worked out. Cultured caviar facilities, using non-Caspian or hybrid sturgeon species, are currently springing up around the world, and will likely provide the market with a high-quality product in the near future. Tragically, Russia will have lost one of its most traditional resources in the process. Once at par in economic value with oil production, it has now plumetted to only a tiny fraction of its former value. Rather than protecting all sturgeon species under the Washington convention, the best possible measure for keeping Caspian species from becoming extinct may be sturgeon-for-caviar farming elsewhere, since it may relieve pressure from the natural populations, and strongly reduce the demand of the world market for Caspian-derived caviar.

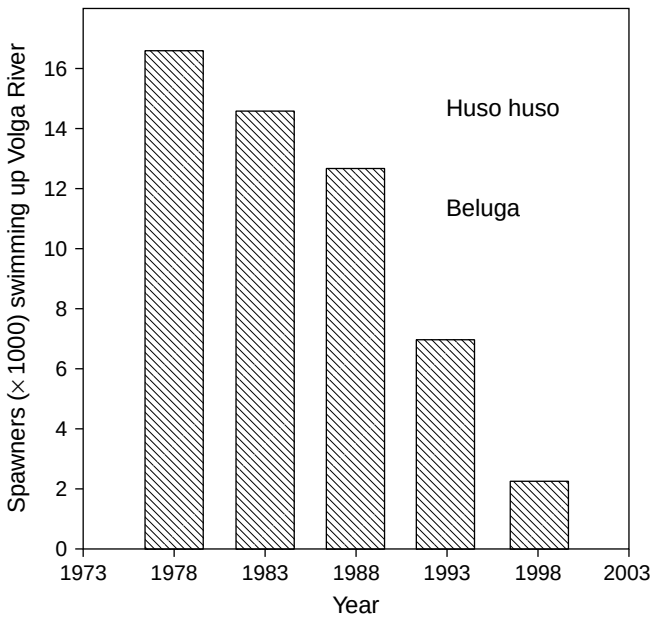

Figure 2 The decline of the Caspian population of Beluga in the late 20th century, as measured by the number of adults swimming up the Volga River to spawn

INTERNATIONAL EFFORTS AT REHABILITATION

The disintegration of the Soviet Union, the dominant player in the region, created a new and complex political situation, with five instead of two riparian nations. Much previous legislation became obsolete, and cooperation between the new states was initially wrought with problems of distrust and con icting interests. Kazakhstan and Azerbaijan gained a sudden strategic importance because of their proven or expected oil reserves, most of which lie below the bed of the lake. A legal tangle developed around the status of the Caspian: lake (in which case it would be divided into five sectors), or sea (with the law of the sea allowing each coastal state a limited zone of exclusive economic rights, besides a vast common zone)? This delayed the development of a common policy in environmental matters, in spite of efforts since 1994 by the World Bank, the United Nations Development Programme, and the United Nations Environment Plan to start a major Global Environment Facility (GEF) project addressing the most pressing issues of the lake. Shortly before the close of the century, a GEF and a TACIS (European Union funded) program was finally launched, aiming at mitigating environmental degradation, and regulating the exploitation of the living (mainly fish and seal) and non-living (mainly oil) resources of the basin.

Among the initiatives taken by this programme, a meeting in Baku, in late April 2001, should be cited, in which experts and government officials tried to work out a strategy to counteract the *Mnemiopsis* invasion, which already showed signs of affecting the sardine populations, and even the seals. An agreement was reached that, as soon as *Mnemiopsis* biomass would reach $1\,\mathrm{Kg\,m^{-2}}$ (wet weight), the procedure for an intentional introduction of *Berae cf. ovata*, a jelly predator of *Mnemiopsis*, should be initiated immediately.

Mediterranean Sea

Michel Batisse

Centre D'activitees Regionales du Plan Bleu, Sophia Antipolis, France

The word Mediterranean stands for 'in the midst of lands'. Indeed the Mediterranean Sea - a large, deep body of water extending from Gibraltar to the Dardanelles and the Suez Canal - is totally surrounded, and even encroached, by its bordering lands and innumerable islands. While these lands and islands have long been referred to as the Mediterranean region, the actual limits of this region are hard to de ne on a map. It enjoys a characteristic climate, with a dry summer season and irregular winter rains, but this climate extends to non-bordering countries like Portugal and Iraq. It is the land where the olive tree grows but this is dif cult to delineate. The entire territory of the bordering countries, some of which are only partly Mediterranean like France, Morocco or Turkey, should be considered when discussing environmental policies and regulations. The catchment basin - excluding the upper Nile - is a useful frame for water-related issues. The administrative coastal regions, with their nearby rugged hinterlands, provide the most useful set of truly Mediterranean data. The coastal fringe has to be considered for urbanization, tourism, etc. Thus, what is known as the Mediterranean region has a variable geographic dimension depending on the issue under study.

CONTROLLING MARINE POLLUTION

Environmental concern in the Mediterranean was originally focused on marine pollution. Twenty-five years ago, this resulted in the adoption, under the auspices of the United Nations Environment Programme (UNEP), of the Barcelona Convention for the protection of the Mediterranean Sea against pollution. This convention has given birth to a number of related protocols and is accompanied by a Mediterranean Action Plan to facilitate its implementation in a broader context of cooperation. The most remarkable feature of this regional effort is that it associated all bordering States, without exception, in spite of their various and well-known political disputes, around common objectives.

Contrary to what has been somewhat over-stated, the Mediterranean Sea as a whole is not much more polluted than other parts of the world ocean. What is true is that it constitutes a major navigation route, with some 300 oil tankers at sea at any one time. The Mediterranean is also a major touristic zone, with millions of vacationers and their myriad of sail boats. As result, the high sea is subjected to an unreasonable amount of oating debris–particularly plastics – as well as by tar balls originating from illegal deballasting and tank washing operations. These latter practices are now more or less under control, thanks to the implementation of MARPOL 73/78 (*see* MEPC (Marine Environment Protection Committee), Volume 4) and of the protocols of the Barcelona Convention relating to dumping from ships and to cooperation in case of emergencies. It is worth noting that the Mediterranean waters have also a relatively high mercury content. This, however, is due to natural sources and would present some health hazards only if a very large amount of seafood were consumed.

The most serious problem lies in the pollution of coastal waters. This pollution comes mainly from domestic and industrial ef uents from the coastal regions, which are the home of some 150 million people to which some 120 million visitors each year should be added, and from the discharge of all the rivers in the basin, which carry solid and liquid waste from the hinterland, including agricultural pesticides and fertilizers, which have caused important algal blooms in the Adriatic.

Much has been done over the last two decades to reduce local sources of pollution, particularly along the northwestern industrialized coast and also in some critical areas such as Kastela Bay in Croatia and Izmir in Turkey. More than 50% of the Mediterranean coastal towns with a population over 10 000 are now served by wastewater treatment plants and half of these have secondary treatment. Yet the others, as well as many industries and isolated tourist resorts, still discharge their ef uents directly, and some 9 million cm^3 of untreated wastewater go to the sea each day. Some 5 million tons of urban solid waste further compound the overall pollution problem along the coastline

every year. However, the Mediterranean countries have now made the commitment to establish sewage and solid waste disposal systems for all urban agglomerations exceeding 100 000 people by 2005.

The impact of the range of domestic, industrial and agricultural pollutants has been extensively studied under the Mediterranean pollution program (MEDPOL), a component of the Mediterranean Action Plan (UNEP-MAP, 1997). The most important protocol concerning land-based sources of pollution, signed in 1980, was updated in 1996. The time is ready for a major operational effort to reduce remaining pollution hot spots.

FROM THE SEA TO THE LAND

When the Barcelona Convention and the Mediterranean Action Plan were under negotiation in 1975, it was already clear to some people that most of the pollution affecting the sea resulted from the way certain activities were carried out on land and that therefore the effective control of marine pollution would depend on changes in the development process taking place in the bordering countries. On these grounds, it was decided to undertake an in-depth analysis of the environment–development interactions in the entire region, to study how these could evolve and in what way the overall situation of tomorrow would depend on what was taking place or decided today. This component of the Mediterranean Action Plan, based on system-analysis and on future-oriented studies, came to be known as the Blue Plan, a symbolic reference to the color of the sea that the convention was meant to protect (*see* Blue Plan, Volume 4).

The method chosen by the Blue Plan was to define the key elements of the Mediterranean system, to evaluate their current interactions, and then to build scenarios on their possible future evolution. The elements considered at appropriate geographic levels were the following: population dynamics, urbanization, agriculture, industry, energy production, tourism, transport, soils, water resources, vegetation cover and biodiversity, coastal land use, and marine pollution.

This Mediterranean system – particularly when considering the coastal regions – is unique. This results from its long common history, which has forged parallel ways of life, and from its typical geographical features, characterized by the presence of the sea, a unique climatic pattern, a rich endemic biodiversity and a rugged hinterland. However, three major facts lead to strongly contrasting situations between the northern European shore and the southern and eastern shores spreading from Morocco to Turkey.

The first contrast is in demography and in the related issue of urbanization. Populations tend to concentrate in the coastal regions on both sides, due to attraction to the sun and the sea in the industrialized North, and due to rural migration from poor hinterlands in the South. However, in spite of a marked decrease in fertility rates, the southern and eastern countries continue to see their population grow rapidly and become younger, while in the North population will at best remain stable and become older (Figure 1). These two opposite trends have major consequences in terms of employment, food, urbanization, land and water use, steel and cement production and pollution. Thus, the growth of urban population in the south will be difficult to manage in social and environmental terms (Figure 2).

This demographic contrast is the corollary of an equally strong north–south disparity in levels of economic development and quality of life. Even when corrected by purchasing power parity, gross national product (GNP) *per capita* remains seven times higher in France than in Egypt. Twenty Mediterranean countries are currently parties to the

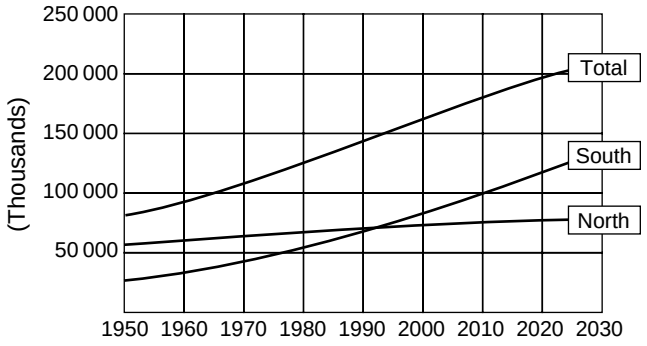

Figure 1 Mediterranean coastal population

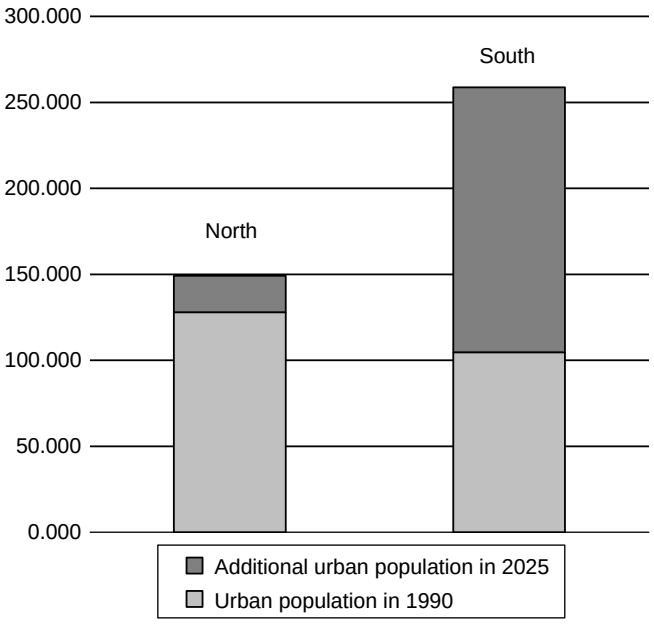

Figure 2 Urban population of the countries of the north and of the south and east of the Mediterranean Basin 1990–2025

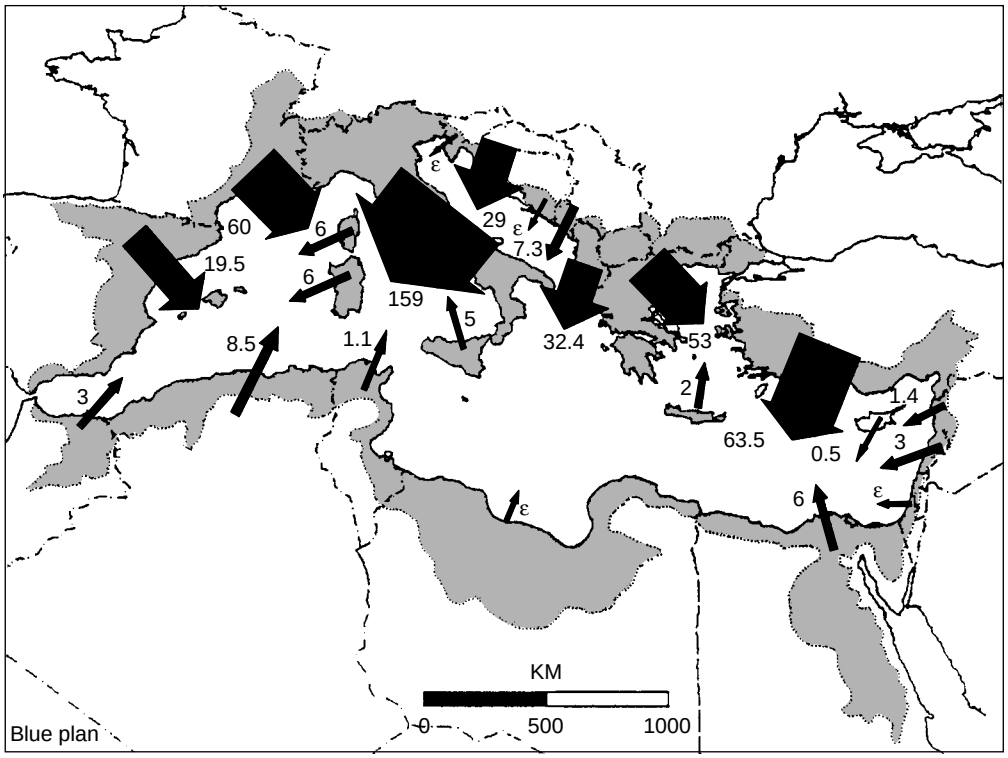

Figure 3 Real annual flows from each country to the Mediterranean (km^3). The grey area represents the Mediterranean catchment basin. The figures given are in billion m^3

Barcelona Convention. For 1998, according to the World Bank, their GNP *per capita* is as follows (US$): France and Monaco 24 940, Italy 20 250, Israel 15 940, Spain 14 080, Greece 11 650, Slovenia 9760, Malta 9940, Croatia 4520, Lebanon 3560, Turkey 3160, Tunisia 2050, Algeria 1560, Egypt 1290, Morocco 1250, Syria 1020, Albania 810. Corresponding data for Bosnia, Cyprus and Libya are not available. When corrected by purchasing power parity, disparities between countries are somewhat smaller.

A third and equally significant contrast results from the difference in water availability. While the term *Mediterranean climate* suggests a common pattern, rainfall is far lower in the South than in the North. In addition, the northern shores (including Turkey) are backed by humid regions providing important river ow, while the southern countries are backed by deserts, with negligible supply. The Nile was once a major exception, but its out ow has almost totally disappeared since the Higher Aswan Dam was constructed (Figure 3). In terms of climate change, the studies conducted so far seem to indicate a possible increase in aridity and in rainfall variability.

The Blue Plan scenarios, built upon coherent sets of assumptions for the period extending from 1985 to 2025, illustrate the likely consequences of different development, environment and cooperation strategies on the future of this Mediterranean system. This *prospective* approach was applied for the first time to such a vast region and could possibly be used in other parts of the world. It amply demonstrates that trend scenarios, even favorable ones based on strong economic growth, lead to serious inequities and more or less irreversible environmental damage due to excessive pressure on resources for the southern and eastern countries – particularly on the coast – and are therefore not acceptable. Only scenarios that take into account environmental protection and social equity, combining appropriate national strategies with enhanced Mediterranean cooperation, lead to what could be called sustainable development for the entire region and could therefore avoid major domestic and international tensions (Grenon and Batisse, 1989).

Clearly, sustainable development in the Mediterranean cannot be achieved independently of what will take place elsewhere, since the region is not isolated economically and technologically from the rest of the world. However, it represents in many ways a microcosm of the entire planet and its future prosperity depends upon a number of imperatives which may be of relevance to other areas. These key imperatives, derived from the conclusions of the Blue Plan scenarios and endorsed by the Mediterranean countries, can be summarized as follows:

1. to incorporate *a priori* (rather than through corrective measures) the protection of the urban, rural and natural

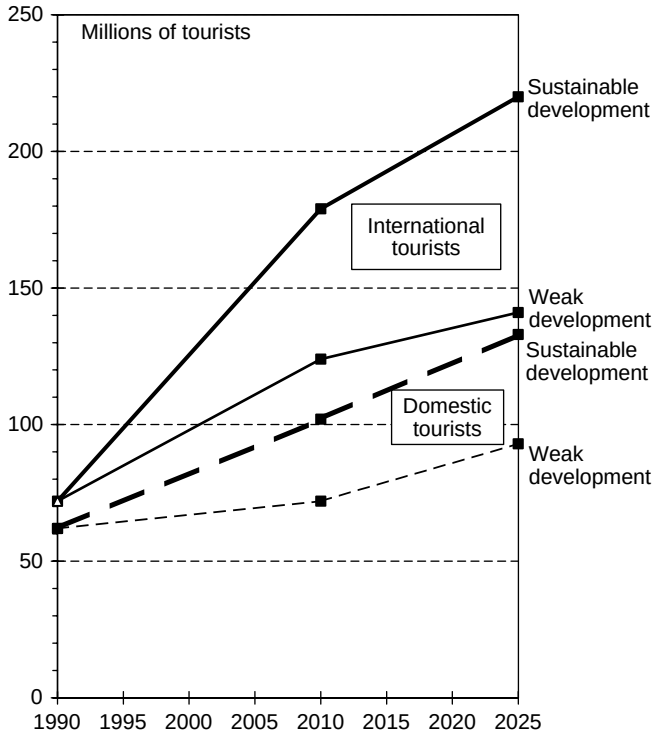

Figure 4 International tourists and domestic tourists in the Mediterranean coastal regions (according to two scenarios)

environment in all development strategies and projects in the region;

2. to ensure integrated management of coastal areas and of the coastal fringe (on both the terrestrial and marine sides), which constitute major natural resources for all Mediterranean countries, notably for tourism; the development of international tourism is essential for most countries in the region for their balance of payments; at the same time, sustainable development increases also domestic tourism (Figure 4);
3. to ensure integrated management of water resources, stressing improved management of water demand, particularly for irrigation; water resources *per capita* have already fallen below the level of stress of $1000\,m^3\,year^{-1}$ for all countries between Morocco and Syria except Lebanon (Benblidia *et al.*, 1997);
4. to promote through education and the media a better perception by all concerned – including decision-makers and the general public – of the economic, social and environmental interactions in the region;
5. to develop and effectively implement economic cooperation between the countries of the European Union and the countries south and east of the Basin, and also amongst the latter countries themselves, favoring bilateral and regional programs and projects of sustainable development.

CHANGING THE SCENARIO

While the Mediterranean countries have not yet taken sufficient measures to meet the above imperatives, a number of positive developments indicate progress is being made. The question is rather whether the pace of progress in policies and actions is sufficient to counter the negative trends, which have to be reversed.

In this respect, a first requirement is to properly assess and monitor the environmental situation. While demographic and economic data are usually available, environmental data are often missing or very localized. The Blue Plan, which is acting as a Mediterranean Environment and Development Observatory has stimulated the establishment of corresponding national observatories in such countries as Lebanon, Morocco, Syria, Tunisia and Turkey, while official bodies in the European countries are fulfilling the same functions.

As a follow-up of the United Nations Conference on Environment and Development (UNCED), the Tunisian authorities convened in 1994 a ministerial conference on sustainable development in the Mediterranean, which formulated an Agenda MED 21, as an adaptation of Agenda 21 to the specific features of the region.

In 1995, 20 years after its adoption, the Barcelona Convention was amended in order to extend its scope beyond marine pollution and in particular to include protection of the coastal regions (as defined by each country within its own territory). At the same time, the protocols of the Convention concerning dumping from ships and specially protected areas were strengthened.

The Mediterranean Action Plan itself entered a second phase, referring explicitly to the sustainable development of the coastal areas of the region, including activities aiming at the integration of environment and development in such sectors as agriculture, industry, energy, tourism, transport, urban management, water resources, soils, living marine resources, forest and plant cover, conservation of nature, landscapes and sites, in addition to the previously carried out measures relating to the assessment, prevention and elimination of marine pollution.

The budget collectively fixed by the bordering countries and the European Commission for the implementation of the Mediterranean Action Plan hardly exceeds 6 million dollars per year, which could appear to be totally disproportionate relative to the ambitious tasks to be covered in this vast region. It should be stressed, however, that these very limited funds are primarily meant to catalyze individual actions by the various countries and to harmonize such actions in the region. While it would be difficult and somewhat artificial to provide a figure for the total effort of Mediterranean countries to respond to the challenge of environmental issues, it is widely recognized that the existence of the Barcelona Convention and of the Mediterranean

Action Plan has begun to change the situation in the right direction.

It should be also noted that the Convention and the Action Plan have triggered important sustainable development projects supported by international financing organizations. Thus, the World Bank, the European Investment Bank, the United Nations Development Programme (UNDP) and the European Commission have joined forces since 1990 in a Mediterranean Environment Technical Assistance Program (METAP) which has sponsored a full array of projects in the southern and eastern countries of the region, concerning such issues as environmental performance indicators, urban water treatment, solid waste disposal, coastal areas management, capacity building, establishment of cooperative networks, etc.

In the same vein, the Mediterranean region provides an ideal place for implementing projects relating to international waters and to biodiversity under the Global Environment Facility (GEF). Thus, on the basis of the work carried out under MEDPOL, a very important scheme is underway for effective control of land-based pollution hot spots. A Strategic Action Program has been prepared and a first year project amounting to some 13 million dollars (including a contribution from the French GEF) allows concrete actions to begin. Similarly, UNDP/GEF is committed to a project aimed at the protection of coastal and wetland ecosystems amounting to some 13 million dollars and covering Albania, Egypt, Lebanon, Morocco, Tunisia and Palestine. Here again, it should be stressed that METAP and GEF funds require counterpart financing by the recipient countries, usually of a far greater magnitude, thus demonstrating their commitment towards environmental improvement.

SUSTAINABLE DEVELOPMENT, SECURITY AND SOLIDARITY

Now that environmental issues have been identified and important steps have been and are being taken to solve them, the path towards sustainable development must be defined. In this respect, responding to the 1995 ministerial meeting in Tunis, the contracting parties to the Barcelona Convention have decided to set up a Mediterranean Commission on Sustainable Development (MCSD). This is an interesting body, which brings together representatives from all bordering countries and the European Commission together with representatives from a number of local authorities, of socio-economic actors and of non-government organizations. While this commission has only a consultative status, its in-depth reports on certain issues like sustainable development indicators, management of water demand, sustainable tourism, etc., provide a common framework for all actors concerned in the region and a basis for formulating projects to bring to the attention of financing bodies.

At the same time, at the national level, most Mediterranean countries as well as a number of regions, provinces and cities in the Basin are preparing their own Agenda 21 and their own plans in accordance with the recommendations of the UN Commission on Sustainable Development and of MCSD. It is interesting to note for example that all countries recognize the need to limit and plan to reduce the share of irrigation in their total water demand which, difficult as it may be, represents the best approach to avoid situations of scarcity (Figure 5).

Much more, however, is needed. As shown by the Blue Plan scenarios, responding to environmental change in the Mediterranean cannot be dissociated from the question of balanced and equitable development in the region, which in turn implies deliberate solidarity between North and South. This part of the world has too long been cursed by international or domestic con icts, be it in North Africa, in the Near East or in the Balkans and the time has come for an effective partnership.

It is encouraging to note that the European Union has become aware of the mounting dangers which the current demographic, economic, social and environmental trends would bring to the region if a serious cooperation effort was not undertaken. As put by French President Chirac in

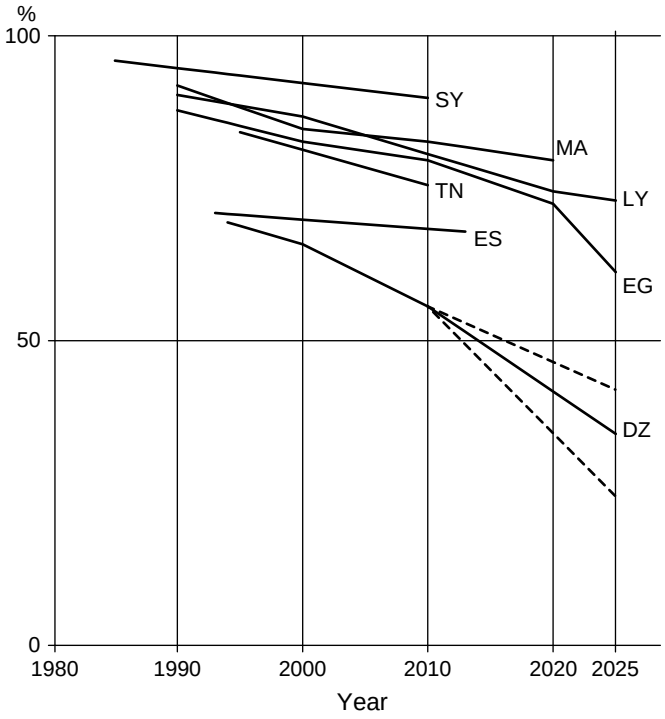

Figure 5 Projections of irrigation shares in the total water demands in some Mediterranean countries (as indicated in national plans). DZ, Algeria (three scenarios); EG, Egypt; ES, Spain; LY, Libya; MA, Morocco; SY, Syria; TN, Tunisia

an address to students in Cairo: after breaking a wall to the East, Europe must now build a bridge to the South . In November 1995, the Ministers of Foreign Affairs of the European Union and the southern and eastern Mediterranean countries met in Barcelona to adopt a declaration of major significance. Its aim is to guarantee peace, stability and prosperity in the region and in particular to set it up as a free-trade zone by 2010. In order to reach these objectives, the decision was made to carry out from 1997 onward a number of cooperative projects between the European Commission and the other countries concerned on a bilateral or regional basis. A mechanism and a fund called MEDA were set up to implement this program. The fund amounts to some 5 billion dollars for the first 3 years and currently being renewed.

Under the economic cooperation component of this program (the other two focussing on security and on culture), it is important to note that agriculture is excluded, but that both environment and water are given a significant place. Thus, under MEDA a basin-wide information system on technical know-how concerning water, Euro-Mediterranean Information System (Emwis), is already in place, a short- and medium-term action program for the environment has been approved (Short and Medium Term Priority Environment Action Program, SMAP) and the Blue Plan has been entrusted with a project for developing environmental statistics in the region.

Like elsewhere in the world, the objective of sustainable development in the Mediterranean is ambitious and complex and requires major changes in the behavior of all economic and social actors. This region, however, may well offer some comparative advantages in this respect. The environmental issues have been thoroughly analyzed, mechanisms for north–south cooperation have been established, bordering countries demonstrate growing commitment, and the European Union has the means to provide the fuel for change. Much will however depend on political stability and on the strengthening of the democratic process in the south. Much will also depend on the continued support of the people from the European countries which do not border the Mediterranean. Many of these people indeed come each year to enjoy its unique natural and cultural heritage and should contribute in some ways to its conservation.

Aral Sea

Michael Glantz

National Center for Atmospheric Research, Boulder, CO, USA

The Aral Sea is a terminal inland sea that is sandwiched between two Central Asian deserts. The existence of the sea depends on the inflow from two major rivers: the Amudarya and the Syrdarya. Their combined flow at one time equaled 110 km^3 per year. In 1960, the sea was the fourth largest inland sea on the globe. Today, just four decades later, it has fallen to sixth place. There is little doubt as to the cause of the shrinking of the Aral Sea, both in volume and in surface area. Decisions to divert water from the two major rivers that have fed the sea for millennia have resulted in less water reaching the sea. Evaporation from the sea surface no longer balances the annual inflow from the rivers. In this short span of time the level of the sea has dropped from 53 m in 1960 to 36 m in the late 1990s. This has caused the sea to divide into two parts: the Little Aral to the north fed by the Syrdarya and the Big Aral to the south fed by the Amudarya. Its surface area decreased from 66 000 km^2 in 1960 to 32 000 km^2 in the mid-1990s. Water salinity also increased in this period, changing from up to 10 g l^{-1} in 1960 to more than 35 g l^{-1} in the 1990s, the same level of salinity as the open ocean. If sea level continues to drop another 5 meters or so, the sea will break up into 12 small saline ponds.

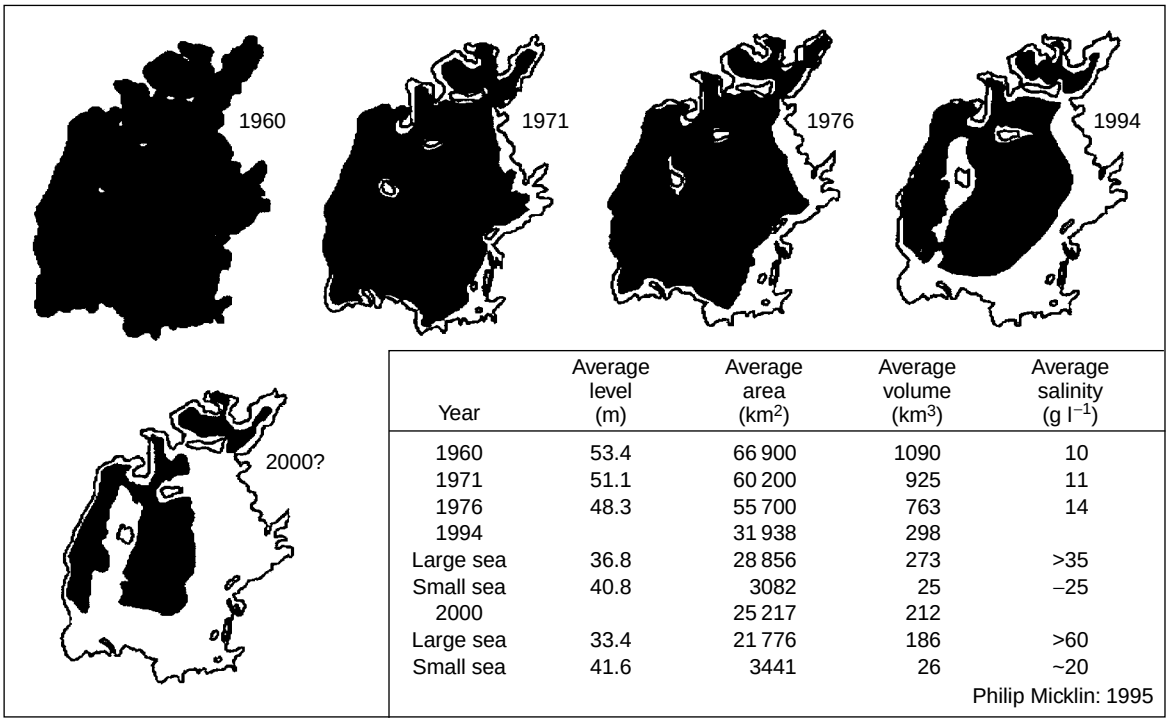
The demise of the Aral Sea (Figure 1) has been called one of the worst human-caused environmental disasters of the 20th century. A review of historical information about the Aral region shows that the drop in sea level was not an unanticipated result of decisions to divert water for irrigation purposes into the desert landscape. If and when the sea disappears, as will likely happen in the next couple of decades, it will have followed a scenario that had been suggested in 1927 by Russian scientist V V Tsinzerling. About 50 years later, Victor Kovda, Professor of Soil Science at Moscow State University spoke frequently of the plight of the Aral Sea when he was the President of the International Council for Science (ICSU)'s Scientific Committee on Problems of the Environment (SCOPE).

The problem started in the 1950s. It was then that decisions were made in the Kremlin by Communist leaders of the Soviet Union to expand the area under irrigation in Central Asia's Karakum and Kyzylkum deserts. The goal was to increase sharply cotton production in the arid Central Asian Republics (CARs), a region with almost perfect conditions for growing cotton, except for the lack of water. That agricultural boundary constraint could be remedied, however, by massive water diversions to the fertile but dry desert sands. As a result, the area under irrigation in the region was expanded from 4 million ha to more than 7 million ha in just a few decades. In the mid-1950s the construction of the Karakum Canal was begun. The canal diverts an estimated 10–15 km^3 per year of water from the Amudarya into Turkmenistan. Today, this canal is the longest human-built canal in the world with a length of about 1400 km.

In the late 1970s the Syrdarya, and in the late 1980s the Amudarya, failed to reach the sea at all. In the early 1990s, the rivers' flows reached the sea once again, as a result of abundant snow pack in the Pamir and Tien Shan mountains, the source of water for these rivers.

Water diversions from the rivers were only part of the region's environmental problems that were related to the rapid expansion of irrigated cotton production. In the process of increasing cotton yields, massive amounts of fertilizers, pesticides and herbicides were used, based on the belief that if a small amount is beneficial, then a big amount would be much better. Large portions of these chemicals eventually made their way into drainage ditches, the groundwater and finally back into the rivers and ultimately the sea. Eventually, they ended up in the fish and in the drinking water.

As the sea dried and its shoreline receded, the newly exposed seabed, containing salts and other agricultural chemicals, became exposed to wind action as early as the mid-1970s. Dust storms were generated that were large enough to be seen from space by Soviet cosmonauts. The storms filled the air with toxic substances, depositing them on agricultural fields at a distance of a few hundred



Year	Average level (m)	Average area (km^2)	Average volume (km^3)	Average salinity ($g\ l^{-1}$)
1960	53.4	66 900	1090	10
1971	51.1	60 200	925	11

Philip Micklin: 1995

Figure 1 The changing profile of the Aral Sea 1960–2000. (Reproduced with permission from Springer-Verlag Micklin and Williams, 1996)

kilometers to the south and west of the sea. The combination of air and water pollution had major adverse effects on the health status of the population living immediately around the Aral coastline. This area, known now as the disaster zone, has deteriorated sharply, leaving many inhabitants of the region with birth defects, short life expectancy, anemia, and several other serious illnesses.

Although various Russian scientists bravely cautioned Soviet political leaders for decades about the adverse environmental impacts on the sea and the fishing sector that depended on the sea, the poor decision-making was not exposed until Mikhail Gorbachev became the Secretary General of the Communist Party of the Soviet Union in the mid-1980s. At that time his new policy of *glasnost* (openness) exposed the Aral crisis to the Soviet public as well as to the rest of the world.

Since then, there have been many national and international workshops and conferences to discuss the future use of regional water resources and the fate of the sea and its surrounding territory. One of the more popular ideas put forth initially by World Bank consultants was to let the sea disappear but to preserve the deltas of the Amudarya and the Syrdarya. The deltas are important wetlands that are biologically productive for both ora and fauna native to the region. Another less popular earlier suggestion had been to divert water from Russia's north- owing rivers to the south to replenish the Aral Sea and to provide additional water for cotton and rice production in the region. Yet another more recent proposal has been to transfer water (uphill) from the rising Caspian Sea to the declining Aral Sea, 400 km to the east (Dukhovny and Sokolov, 1997).

At one time the sea had supported a robust fishing industry that captured upwards of 50 000 metric tons per year of various commercially favored species and employed tens of thousands of inhabitants in the region. As the water quantity declined, the Aral's seaports of Aralsk and Muynak became separated from the receding coastline by tens of kilometers. The desiccated seabed was strewn with abandoned and rusting fishing vessels (Figure 2), an image which has since become a symbol of the degradation of the sea and human health as a result of deliberate political decision-making.

As the water quality declined, the fish population declined with it. Eventually, the Soviet government imported fish into the region from the Pacific Ocean and from the Baltic Sea to keep the fish processing factories operating. Finally, this became too costly and the practice was discontinued.

For a few years after the breakup of the Soviet Union in December 1991, the newly independent CARs – Kyrgyzstan, Turkmenistan, Kazakhstan, Uzbekistan, Tajikistan – voiced their common goal as Saving the Aral Sea . However, it became clear almost immediately that it was a goal that they could neither attain nor one they had the desire to reach. Sustaining cotton production remained a primary objective as the way to generate sorely needed foreign exchange to be then used for

Figure 2 The skeleton of a boat stands in a sandy desert that once was the port of Muynak, now tens of kilometers from the Aral Sea (photo by M H Glantz)

economic development. There was no voluntary reduction in irrigation, or in the acreage devoted to cotton production. Irrigated land, however, had to be abandoned because of poor yields or extreme soil salinization. There has also been a sharp reduction in the use of agricultural chemicals, not because of their adverse impacts on human settlements and ecosystems, but because of their high cost.

Despite the political rhetoric to the contrary, there is still competition among the CARs for control over the limited water resources in their region. With newly found independence, the Republics' leaders have shown reluctance to compromise on their perceived national water needs, although there are local, national and regional attempts to make more efficient use of that water. Problems related to water sharing are likely to continue in the future as upstream countries (Kyrgyzstan, Tajikistan, Afghanistan) seek to increase the use of water within their borders.

An important characteristic of the Aral Sea that has apparently been overlooked by the five CARs and donor nations is its symbolic value. Environmental and other groups around the globe have shown considerable interest in the fate of the sea since the mid-1980s. If the CARs were to let the sea break up into a dozen or so small saline ponds, it is highly likely that many of those groups will turn their attention, interest and resources elsewhere to other serious environmental problems for which their involvement could make a difference.

In the absence of major changes either in the national policies of the five CARs or in a natural increase in river flow to the sea, the sea will likely disappear in the not too distant future. As it is today, the remnants of the sea could serve as an example of what happens when societies do not respect the limits on the use of their technologies and the limits of Nature to absorb the insults of misapplied human activities on a fragile environment.

To protect the Aral Sea from further degradation, it has been suggested that the sea in its current state be given World Heritage Site status by UNESCO (United Nations Educational, Scientific and Cultural Organization). This designation would mean that the countries in the Aral Sea basin would have a responsibility to preserve the sea at least at its present level; and it would also oblige the international community to support the CARs in their efforts to protect the sea. As a heritage site, the Aral Sea would serve as a constant reminder of the failure of a political system to protect the fragility of the natural environment.

Great Lakes Region of North America

Henry Regier[1] and Linda D Mortsch[2]
[1] *University of Toronto, Toronto, Canada*
[2] *Waterloo, Canada*

Region-wide efforts to correct particular abuses of modern industrialization and urbanization began late in the 19th century, and have expanded and intensified gradually

since then. Regional manifestations of some global problems came into focus in the 1980s; preventive and adaptive efforts then began slowly. Particular regional initiatives are described concerning several global issues: hazardous contaminants; climate change and stratospheric ozone depletion; and water diversions and allocations as related to commodi cation of water in free trade.

INTRODUCTION, THE GREAT LAKES REGION

The waters of the Great Lakes are an integral part of the natural and cultural heritage of eastern North America, and have global recognition as valued ecosystems. Scores of small nations of Aboriginal peoples of the Anishinabek and Haudenaushaunee cultures, as well as many people of the two larger nations of USA and Canada, live here with a total population of over 33 million people. Spanning some 1200 km from west to east, the chain of lakes, with connecting and outlet rivers, is fed by many short rivers, wetlands and groundwater aquifers.

Starting in the 19th century, the southerly part of the Great Lakes Region gradually became strongly industrialized with steel and petrochemical works and related manufacturing as well as intensive agriculture and related processing. The sparsely-settled northerly hinterland of the region provided natural resources for the southerly industrial heartland. Fresh water for manufacturing and domestic use was inexpensive and in such abundance that cheap hydroelectric energy from its ows and ship transport on its surface contributed greatly to the modern development.

Interjurisdictional difficulties with sharing of beneficial uses (e.g., fisheries, water) and with limiting of harmful abuses (e.g., dumping human wastes with their pathogens into boundary waters) became region-wide issues late in the 19th century. Formal intergovernmental arrangements to resolve those and numerous other difficulties gradually came into place, issue by issue, during the 20th century. In 1987, Canada and the USA entered into a formal commitment to address the many interactive issues in an ecosystemic context, without intending to defocus efforts to correct priority problems like contaminants. In the following years, many governance institutions at all levels from local to basin-wide then came to accept this ecosystem approach. Implementing it in practice progressed slowly.

In the 1980s it was apparent to opinion leaders here as elsewhere, that some worrisome issues were regional manifestations of continental or global processes (e.g., acid rain, organohalide contaminants, introduction of harmful exotic species). Then some global issues that had not yet attracted much notice in the region came to be recognized here, too (e.g., climate change, loss of biodiversity, spread of harmful exotic species, commodification of water within free trade, stratospheric ozone depletion, urban sprawl in the coastal zone with in ux of many humans).

GENERAL FEATURES OF RESPONSES TO GLOBAL CHANGE

Until the mid-1980s, the basic approach to resolving region-wide problems in the Great Lakes involved primary leadership and funding by the two federal governments, in formal cost-sharing partnerships with the states and province. In effect, these governments had accepted the primary onus to correct matters, and mostly at their expense. The countries created a number of binational commissions to help with this work. Within jurisdictions, there evolved numerous kinds of regulations, with each set delegated to matching agencies in different jurisdictions and with transboundary connections among agencies. Higher levels of government helped to fund clean-up efforts of several kinds. Meanwhile, some of the worst industrial polluters abandoned their obsolescent plants to become derelict brownfields or gradually rebuilt them with better technology. By the mid-1980s this command and control approach was recognized to be less than optimal politically, economically and environmentally. This realization emerged at about the time that a series of global issues were recognized to have important regional and local aspects.

Pessimistic realists perceive events since about 1985 as a retreat by the two higher levels of government from environmental responsibilities. Optimistic idealists perceive that redemocratization is occurring with governance at a more appropriate level. The latter involves, in turn, a shift of primary onus to that level, under appropriate formal guidance by senior levels of governance. Overall, this process did not proceed smoothly.

With environmental uses and abuses generally, it has come to be accepted, in theory, that the person, corporation or agency intervening in the natural environment must bear a strong onus to act appropriately and to provide evidence of proper behavior. Costs of environmental stewardship have increasingly been internalized within the interveners' financial accounts. Industry associations have formulated codes of ethics for participating corporations, and these have been enforced occasionally. Professions have updated their codes a little. Governments have been considerate of failings where some evidence of good faith has been offered. These reforms, proceeding haphazardly, had not gotten far in the Great Lakes Region by the end of the 20th century, and the prognosis was uncertain. Again, pessimists feared a relapse into severe further degradation, while optimists hoped for continued gradual rehabilitation of the harm done by past abuses as well as successful prevention or counter-action of new abuses.

A COMBINED TECHNICAL AND POLITICAL INITIATIVE ON CONTAMINANTS

The 1978 binational Great Lakes Water Quality Agreement had as an objective zero discharge and virtual elimination

of hazardous contaminants such as certain organohalides. Large funds were committed toward this end by different levels of government and corporations. Hundreds of citizens participated in creating and implementing *Remedial Action Plans* concerning contamination and other problems in 43 severely degraded *Areas of Concern* around the shores of these lakes and their connecting rivers. Areas of Concern included Green Bay (WI), Saginaw Bay (MI), the Cuyahoga River (OH), Buffalo Harbor (NY State) and Burlington and Toronto Bays in Ontario. Many other degraded locales up the tributary streams and along shores were not addressed specifically as part of the binational program.

By the turn of the century, major remediative progress was documented for most of the Areas of Concern and the task of remediation was judged to have been completed in one of the 43 locales; the delisted locale is Collingwood Harbor in Ontario. Monitoring of various organisms that accumulate contaminants provided ambiguous data on the rates of decline and the eventual endpoints attainable. Some researchers inferred that levels of contamination were declining at encouraging rates for most hazardous chemicals, due in part to burial in sediments and to natural degassing of these fugitive substances from the waters to the atmosphere (to be carried mostly northward and eastward to cause harm there). Optimists extrapolated the rates to forecast that most of these chemicals would eventually fall to non-detectable levels later in the 21st century. Assumptions for optimistic forecasts included: that no large deposit of contaminants on the shores of these waters would break out of its burial site, that no major industrial accidents involving spills would occur in the region or upwind of it, and that atmospheric loadings from outside the region would also fall steadily. Pessimistic researchers saw no firm basis in the available data and information for such optimism.

With partial success on the contaminant and other chemical issues, concern about them abated in the region, at least among politicians and civil servants. Experts concerned about newly perceived risks of endocrine disruption urged increased efforts toward zero discharge and virtual elimination. In both countries, the level of governance at which this issue was being addressed appeared to have shifted from the federal level: in part to the maker and user of such a substance interacting with the local community; and in part to the international level with respect to guidelines on the trade in these materials. At both the local and global levels the governance institutions were evolving slowly.

PRECAUTIONARY APPROACH TO DIVERTING AND EXPORTING FRESH WATER

The quantity and quality of Great Lakes waters have been a recurring concern at all levels of governance since the 19th century. Waters naturally flowing out of this chain of lakes northeastward into the Gulf of St Lawrence and the Atlantic Ocean were perceived by some to be wasted. Ecologists have found that these outflows into the marine system have major beneficial effects there; thus there is no waste.

The city of Chicago has diverted water from Lake Michigan to flush effluents from poorly-treated sewage into the Mississippi River system. Large agricultural and urban users of water to the southwest of the Great Lakes, with costs often subsidized by governments, have long sought further governmental subsidies to help negotiate and divert water to them from the Great Lakes.

Regional assessments of the effects of the various scientific scenarios of global climate change on the levels and flows of water in the Great Lakes are not consistent. The precautionary principle requires an emphasis on preventing strongly adverse possibilities (*see* Precautionary Principle, Volume 4; Precautionary Principle, Volume 5). Partly for this reason, and partly because fresh water in bulk quantities may become a commodity under free trade, the various levels of government in the region turned to a binational commission for advice on the issue. The policy recommendation invokes a precautionary approach and urges against further diversions and exports of water in bulk quantities. Protection of the integrity of regional wetland ecosystems, with the integrity strongly dependent on a natural hydrologic regime with marked fluctuations, is a key consideration.

Aboriginal peoples are particularly concerned about the issues of water removal from this region. Their cultures are closely linked to aquatic realities of regional ecosystems and they may perceive their treaty rights to be violated by diversions and bulk withdrawals of water. This issue may provide a stimulus for the Aboriginal peoples to organize as federations to participate effectively in regional and global issues.

A NO-REGRETS TECHNICAL INITIATIVE IN TORONTO

In the older, larger cities of the region, the urban infrastructure had aged late in the 20th century. Water supply, sewage collection and treatment, heating and cooling of buildings all were old and inefficient, and becoming more so. Cooling devices still used halomethane gases some of which escaped into the atmosphere to cause stratospheric ozone depletion. Heating was done in part with steam and electricity from the combustion of fossil fuels with the production of carbon dioxide, a greenhouse gas. In the 1990s the city of Toronto, motivated in part by concerns about climate change and stratospheric ozone depletion, embarked on a phased process to address its local issues in a coordinated way.

Toronto is located on the shore of Lake Ontario, which is deep with a large mass of cold water year round at depths below about 25 m. Toronto withdraws domestic water from this deep cold water. With domestic water supplies, there is no particular advantage to cold temperatures as such. So incoming cold water could be used as a heat sink in a heat exchanger; the ice slurry produced in the exchanger could then be piped to buildings for cooling purposes. (Some large buildings in the city need to be cooled even in the dead of winter, because of the buildings' insulation against summer temperatures and the heat given off by electronic equipment and respiring humans.) The warmer domestic water might lead to warmer sewage and more rapid decomposition of sewage wastes.

The ecological effects, on land and in water, of such deep lake-water cooling are expected to be complex. No disastrous ecological effects have been forecast. Among the desirable effects are reductions in the release of gases that cause stratospheric ozone depletion and climate warming.

EFFORTS RELATED TO CLIMATE CHANGE

In the 1970s some meteorologists in the Great Lakes Region feared that global cooling was underway. There had been controversy between the protagonists of cooling and of warming in that decade. By the mid-1980s however, the concern about warming came to be taken more seriously by increasing numbers of researchers; and numerous scientific activities have been mobilized. Most assessments of ecological and other effects took one or more of the global climate simulations as plausible scenarios, and then sought to infer likely climatological and other consequences for this region. At the end of the 20th century, there remained important inconsistencies and uncertainties among the regional interpolations of different global simulations, and these contributed to political confusion concerning the urgency of practical actions aimed at reversing climate warming. The general approach taken was to assign somewhat higher priority to existing commitments on extant environmental abuses that were also likely to contribute to climate change, i.e., a no-regrets approach (*see* No Regrets Principle, Volume 4). Some of these initiatives have been sketched above.

Versions of an ecosystem approach are coming to be standard with environment-related planning and decision-making in the region. Global issues, including climate change and stratospheric ozone depletion, may be included explicitly in the larger biospheric context for a particular ecosystem within the region. The various principles of the United Nations' Agenda 21 (precautionary principle, sustainable development, equitable sharing, sensitivity to aboriginal peoples) may also be taken into consideration. Admittedly, this is an optimistic interpretation.

Lake Victoria

G O Obasi
World Meteorological Organization, Geneva, Switzerland

Lake Victoria, the second largest freshwater lake in the world, has unique hydrological features. It straddles the Equator over Kenya, Uganda and Tanzania, and the catchment area extends to Rwanda and Burundi. The Lake has a surface area of about 67 580 km^2. The mean and maximum depths are about 40 m and 92 m, respectively. Lake Victoria is one of the principal sources of the river Nile which ows out of the Lake north of Jinja (Uganda), for about 6650 km before entering the Mediterranean Sea at Alexandria in Egypt. Its drainage basin encompasses about 3 349 000 km^2 (IDAEL, 1996; Lehman, 1998; UNDP and WMO, 1974). The Nile is the lifeline for the downstream semi-arid countries of the Sudan and Egypt, and has been so ever since the time of the Pharaohs when it sustained the great ancient civilizations.

Millions of people depend on Lake Victoria for their food, water, employment, transport, energy and other socio-economic activities. Some of the challenges to the sustainable utilization of Lake Victoria resources include the rapid growth of population and urbanization in the Lake basin; pollution by urban sewage, industries, and agricultural activities; signi cant competition and potential con icts among various sectoral water-use activities at national and regional levels; and climate variability including droughts and oods (Obasi, 1997a; Obasi, 1996).

HYDROLOGY AND CLIMATE OF LAKE VICTORIA BASIN

The annual rainfall over the Lake area ranges from 800 to over 2000 mm in the Lake interior and accounts for about 80% of the total Lake water input of 15–18 milliards (cubic km) per annum. One-third of the remainder comes from the river Kagera with a drainage basin area of 60 000 km^2 and two-thirds from many streams and tributaries. The mean annual out ow at the only outlet (river Nile) measured over 80 years is about 12.2 milliards. The highest rise in the Lake level of 1.25 m was recorded in 1961, while the lowest level

was recorded between May 1922 and April 1923 (Flohn and Burkhardt, 1985; Hastenrath and Kutzbach, 1983; Indeje *et al.*, 1998; UNDP and WMO, 1974). There are, however, no reliable estimates of sediment loads into and out of the Lake.

The climates of the Lake basin region range from equatorial to arid types. There is, however, plentiful moisture near the Lake due to swamps and other large lakes. The Lake is also known to generate its own climate (Okeyo, 1987; Ogallo, 1988; Sun *et al.*, 1999). For example, a semi-permanent low pressure system that is often referred to locally as the Lake Victoria trough migrates into and out of the Lake during the night and day time respectively, and is associated with significant diurnal rainfall variability.

There are strong seasonal and inter-annual variabilities in the rainfall patterns which are often re ected in stream ow and lake-level uctuations. Recurrences of oods and droughts are quite common in the Lake Victoria basin, and often result in loss of life and property, mass displacement of the Lake inhabitants, destruction of crops, erosion, siltation, and the increase in water-borne diseases. Some of the seasonal variations and extreme weather and climate anomalies in the Lake Victoria basin have been associated with the El Nino/Southern Oscillation (ENSO) phenomenon (Indeje *et al.*, 1998; Mukabana and Pielke, 1996; Okeyo, 1987; Ogallo, 1988; Sun *et al.*, 1999).

Paleoclimatological studies indicate that climate variability and change have been the major cause of the past deterioration of Lake Victoria (IDAEL, 1996).

Climate models indicate a rise in the mean global temperatures of $1-3.5\,^{\circ}C$ by the end of the 21st century (IPCC, 1995). Such warming is expected to give rise to thermal expansion and changes in the level of Lake Victoria. However, the current climate models are unable to provide consistent and skilful regional climate scenarios that are required for projecting the impacts of climate change on the hydrological cycle at the river basin level. This is a major challenge for climate modelers and hydrologists (Obasi, 1997b). Nevertheless, policy decisions can be derived from the current models using a hypothetical range of climate change scenarios.

WATER QUALITY AND SOME ENVIRONMENTAL PROBLEMS

Lake Victoria is experiencing rapid environmental damage. The water hyacinth is the most visible (although perhaps not the most damaging) of all the problems. The plant's ability to absorb pathogens from water is a much-exploited trait utilized in water treatment facilities around the world. However, over Lake Victoria it forms thick mats which clog dams, choke and deoxygenate the waters, destroy the shores and render inaccessible the traditional fishing areas and landing beaches.

Other environmental problems relate to over-fishing, and to the introduction of some health-hazard fishing methods such as fish poisoning. The large Nile perch, which is a relative newcomer, has caused havoc to the ecosystem, decimating certain native fishes and invertebrates. Some species have completely disappeared. These developments raise concern about the sustainability of fish resources. Deforestation around the lakeshores and beyond is another major problem. Improper cultivation of deforested land areas has accelerated the runoff of top soil into the Lake. Industrial pollution is also on the increase. There are no effective waste management programs in place. Thus, the ecological health of Lake Victoria has been significantly affected by the dumping of untreated ef uents by several industries. For example, phosphorous concentrations have risen by a factor of two (from about $0.05\,mg\,l^{-1}$ in the 1960s), algae bloom have increased by a factor of 8–10, the deep waters of the lake are more depleted in oxygen for longer periods of time each year, and filamentous and colonial blue-green algae now dominate the algae community. While the ecosystem changes in the Lake are well documented, the causes of the changes are uncertain due to data limitations.

SOME RELEVANT PROGRAMS OF THE WORLD METEOROLOGICAL ORGANIZATION (WMO) AND OTHER ORGANIZATIONS

Various programs in support of member countries and their regional development plans of Lake Victoria Basin have been implemented, including a WMO/UNDP hydrometeorological survey of the catchments of Lakes Victoria, Kyoga and Mobutu Sese Seko in 1967. Under the project, 25 meteorological stations, 200 rainfall stations and 45 stream-gauging stations were installed.

Several initiatives have also been undertaken by the individual countries, and other UN agencies and bodies including the Food and Agriculture Organization, the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the United Nations Environment Programme. The Lake Victoria Environmental Management Project is one such project undertaken by the Kenya, Uganda and Tanzania through the Global Environment Facility and the International Development Agency funding.

Global on-going programs relevant to the water resources of Lake Victoria basin (Ogallo, 1988; Sun *et al.*, 1999) include:

- Enhancement of real-time and near real-time monitoring, and improvement of the database at national, regional and global levels, for weather and hydrological forecasting and climate prediction. The World

Hydrological Cycle Observing System in particular, will assist in hydrological monitoring and forecasting (WMO, 1998).

- The Hydrological Operational Multipurpose System for the transfer of technology in operational hydrology (WMO, 1998).
- Some research programs implemented jointly by WMO and other international bodies such as the Intergovernmental Oceanographic Commission of UNESCO and the International Council for Science are meant to improve climate prediction and the understanding of the impacts of climate anomalies on water resources. These include the Global Energy and Water Cycle Experiment, and Climate Variability and Predictability study.

SUSTAINABILITY OF LAKE VICTORIA

Sustainable utilization and management for the Lake Victoria water resources in this century will require, among others:

1. An improved observation network including remote sensing capability for monitoring all components of the hydrological cycle and water quality within the basin.
2. An improved capacity for efficient and timely exchange of meteorological and hydrological data and information, and services.
3. An improved database for the whole catchment, including past, present and projected sectoral water use activities. This can enable the planning of integrated and sustainable water policies to be developed in order to minimize con icts over water use.
4. Global warming could result in thermal expansion and lake level rise. It could also result in enhanced evapotranspiration over the lake catchment. Enhanced interdisciplinary research is therefore required in order to properly understand the processes that have been responsible for the past and present hydrometeorological evolution in the Lake Victoria catchment, including the in uence of the ever-increasing human effects on the basin hydrological characteristics.
5. Enhancement of capacity for the development of climate/hydrological models for timely early warning and disaster preparedness.
6. Assessment of the potential impacts of climate change on lake basin hydrology, and the implications of such changes on current and projected future catchment water use activities.
7. Enhanced capacity building at national and regional levels. Most of the countries in the region still lack skilled interdisciplinary human resources, equipment and other basic facilities that are required for optimum application of current scientific and technological knowledge in operational hydrology.
8. The need to promote an appropriate mechanism for closer coordination of water use activities and the associated policies at local, regional, and international levels, including the harvesting of the natural resources of the Lake, and a reduction in the release of wastes into the Lake and rivers.

Nile River

Mohamed Kassas
Cairo University, Giza, Egypt

The Nile Basin is shared by 10 countries, the river spans 35 degrees of latitude with a south to north alignment from the Equator to the Mediterranean. The catchment area is large but the discharge is not: the Sudd swamps of southern Sudan consume most of its equatorial waters, and its northern reaches traverse arid territories that contribute very little water. The geological and cultural histories are complex, the climatic systems that prevail are very different, and climate futures need to be studied within a collaborative program shared by the 10 countries of the basin.

The course of the River Nile runs in a south to north alignment for 35 degrees of latitude: from Lake Tanganyika (Lat. 4 °S) to the Mediterranean (Lat. 31 °N). Its basin is shared by 10 countries: The Congo Democratic Republic, Burundi, Rwanda, Tanzania, Uganda, Kenya, Eritrea, Ethiopia, Sudan and Egypt, and spans a wide spectrum of climates (from humid tropics to deserts), vegetation types, landforms, land uses and human cultures. This basin is one of two biogeographical corridors that link the equatorial and tropical realms in the south with the palaearctic (Mediterranean) realms in the north. The other is the Red Sea. For details see Rzòska (1976). This river has a long and complicated history that relates tectonic–geological events, climate changes and related rise and fall in the Mediterranean water level. Its rudiments go back some six million years, but its present form is recent. Said (1994) recognizes three terminal phases: the beta Neo-Nile (26 000 before present (BP), the gamma Neo-Nile (20 000–12 000 BP), and the delta Neo-Nile (10 000 BP). For details of this history, see Said (1993).

One can conceive the extant Nile as a recent connection of three principal systems: the system that drained waters of the equatorial plateau and formed an inland delta that remained juvenile (the marshlands of the Sudd region of southern Sudan), the system that drained the Ethiopian highlands (rivers Sobat, Blue Nile, Atbara, etc.) and poured onto what was an extensive lake (now the Gezira and Butana alluvial plains of eastern Sudan), and the northern (Egyptian) system that collected waters from several tributaries (now desert wadis) emanating from the Red Sea coastal mountains. The present river collects waters from two sources: the equatorial plateau and the lower plains of southern Sudan and the Ethiopian highlands. The former receives year-round annual rainfall of more that 1000 km^3, but the volume of water it contributes to the northward owing White Nile is about 15 km^3. The lower plains embrace the 700 km long swamp (The Sudd), which seems to consume considerable volumes of water; it receives little water from a western tributary (Bahr-el-Arab) with extensive catchments that comprises parts of southern Sudan, Chad and the Central Republic of Africa. In general, this southern section seems wasteful and invites engineering schemes for improving its efficiency. The Jonglei Canal scheme is one example (a canal that bypasses the Sudd and carries part of the equatorial waters directly to the White Nile). A collaborative program of hydrometeorological studies on the equatorial lakes was initiated in 1967 with the participation of Tanzania, Kenya, Uganda and Egypt and support of the World Meteorological Organization; between 1971 and 1974 Ethiopia, Rwanda, Burundi and Zaire joined the program. This program built a considerable database on the hydrology of these equatorial sources of the Nile.

The Ethiopian sources seem more efficient, only some water is lost in the Machar marshes of the Sobat. The 84 km^3 per year of water reaching Aswan (Egypt) are mainly (83%) Ethiopian waters (13% from Sobat, 58% from Blue Nile and 12% from Atbara); only 17% come from the equatorial sources via the White Nile. Though the Nile is one of the longest rivers of the world, its yearly discharge to its mouth is modest compared with other African rivers (Table 1).

Two features seem to explain this relatively small ow of water; firstly, the considerable water losses of the equatorial sources and secondly its downstream part, from the mouth of Atbara in the Sudan to the Mediterranean (c. 2700 km), crosses an extremely arid region (The Sahara) and contributes almost nothing to its waters. The countries that share this international river, especially the two downstream countries (Sudan and Egypt), built several reservoirs on the Atbara (Khashm-el-Girba), the Blue Nile (Sennar and Roseires), the White Nile (Jebel-Awlia) and the Aswan Reservoir and the Aswan High Dam (Egypt). There is still room for schemes that conserve and tap the considerable volumes of water of the equatorial Nile. The hydropower resources are only partly (c. 10%) developed. There is considerable potential for development in the Equatorial and Ethiopian tributaries and in the principal course of the Nile.

Table 1 Comparison of yearly discharge of the Nile with other African rivers

	Length (km)	Basin (km^2)	Discharge (km^3 $year^{-1}$)
Nile	6700	2 960 000	84[a]
Congo	4700	3 830 000	1248
Niger	4100	1 220 000	192
Zambezi	2700	1 200 000	223

[a] Inter-annual variability is considerable: 120 km^3 in 1916 and 42 km^3 in 1984.

The human history associated with the River Nile provided part of the world cultural heritage: the Pharaonic civilization that ourished in its downstream part (Egypt), and the stories of adventurous travels of the explorers searching for its Ethiopian and equatorial origins. Though the seasonal rise and fall of the River was generally regular (of the 820 oods recorded on the Roda Nilometer between the 7th and 15th centuries, 73% were normal oods, 22% were low and 5% were destructively high (Said, 1993)), the origin of the water remained a mystery. During the middle and new Kingdoms of Ancient Egypt, the empire was extended southward to Nubia and at one time up to Khartoum. Trading missions, via the Red Sea, established posts in the land of Punt (the present East African Horn including Somalia and Ethiopia). Christianity entered Ethiopia (330 AD) by missionaries from Alexandria. All through ancient and medieval history, Egypt believed that oodwater came from highlands of Ethiopia; in years of very low ow, emissaries were sent to ask the king of Ethiopia to let the ood ow to Egypt.

The narratives and reports of expeditions sent to explore the equatorial sources of the Nile by the then rulers of Egypt (Mohammed Ali and his sons) between 1821 and 1840, by the Royal Geographical Society (Great Britain) and the Khedival Geographical Society (Egypt) between 1850 and 1870, and subsequently by British and German governments in East Africa, are contained in a rich series of volumes. The most southerly source of the Nile was discovered in 1937: the two rivers Luvironzo and Nlavarango join and form the Ruvuvu tributary of the River Kagera, which ows into Lake Victoria. The discovery was commemorated by the words Caput Nili inscribed on a small hill to the north of Rutana village (Lat. 4 °S) in Northern Burundi. See Hurst (1952) for a summary and Moorehead (1960) for the story. The story of the exploration of the Ethiopian sources was told by Moorehead (1962). Two names are associated with the 1770s: the French geographer D'Anville who produced a map of Ethiopia and the Blue Nile based on reports of Portuguese missionaries, and the British explorer James Bruce.

Five principal climate systems prevail within the Nile Basin: the equatorial climate of the lakes plateau (rainfall c. 1200 mm year^{-1} with weak bimodal seasonal distribution); the Ethiopian monsoonal climate (summer rainfall c. 750 mm year^{-1}, mainly in June–August); the Central Sudan semi-arid climate (summer rainfall c. 399 mm year^{-1}); the Saharan climate in Northern Sudan and almost all of Egypt; the Mediterranean coastal arid climate with winter rainfall (c. 150 mm year^{-1}). The likely manifestations of global climate change are uncertain. The IPCC (1998) report states that The global change model (GCM) scenarios provide widely diverging pictures of possible future river ows, from 30% increase to 78% decrease •••. There is need for a regional climate modeling effort over the Nile to help reduce this uncertainty . The 10 countries that share the river basin are at present engaged in formulating a Nile Basin Initiative of regional studies towards sustainable management of its resources. A climate research program could be a valuable element of this endeavor.

General

Climate Change Assessment, United States

Michael C MacCracken
Lawrence Livermore National Laboratory, Livermore, CA, USA

In 1997, the US Global Change Research Program (USGCRP) initiated the National Assessment of the Potential Consequences of Climate Variability and Change for the United States. This national assessment included analyses of the importance of climate variability and change in 20 regions around the US, in ve cross-cutting sectors focused around natural resources and public health, and for the US as a whole. Climatically, the hundred-year projections that were used indicated that the climatic conditions of the northern US would become like the central US, the conditions of the central US like those across the southern US, and conditions across the southern US like tropical and subtropical regions. The results of the analyses indicated that there will be signi cant regional variability in both climate change and resultant consequences across the US. Although overall forest productivity was projected to increase for the next several decades, as a result of the carbon dioxide fertilization effect, speci c natural ecosystems were projected to be at signi cant risk because of the very limited potential for their movement and reestablishment. Although the US has abundant water resources, widespread concerns about water resources arose in every region. As a whole, US agricultural production was projected to increase, although those farming marginal lands are likely to be impacted by further reductions in their economic competitiveness. The extensive coastal regions in the US were projected to be exposed to rising sea levels, increasing the risk to extensive coastal infrastructure, barrier islands, and coastal wetlands. Rising temperatures and the accompanying rise in the absolute humidity, were projected to lead to much more uncomfortable summer weather conditions across the southern and eastern US; analyses indicated, in general, that health consequences could be minimized by taking a wide array of public health measures.

As the issue of climate change gained attention in the 1980s as a result of scientific advances and early international conferences, the US Congress passed The Global Change Research Act of 1990. This public law recognized the early scientific findings that human activities were starting to change the global climate, asserting that:

(1) industrial, agricultural, and other human activities, coupled with an expanding world population, are contributing to processes of global change that may significantly alter the Earth habitat within a few generations;
(2) such human-induced changes, in conjunction with natural uctuations, may lead to significant global warming and thus alter world climate patterns and increase global sea levels. Over the 21st century, these consequences could adversely affect world agricultural and marine production, coastal habitability, biological diversity, human health, and global economic and social well-being.

To address these issues, the US Congress established the USGCRP and instructed US federal research agencies to cooperate in developing and coordinating

> a comprehensive and integrated US research program which will assist the nation and the world to understand, assess, predict, and respond to human-induced and natural processes of global change.

The USGCRP has led to coordination of the global-change related research efforts of 10 federal agencies, including the departments of Agriculture, Commerce (specifically the National Oceanic and Atmospheric Administration [NOAA]), Defense, Energy, Health and Human Services, and Interior along with the agency-based research programs in the Environmental Protection Agency, National Aeronautics and Space Administration, the National Science Foundation, and the Smithsonian Institution. While interagency coordination has led to a number of organizational challenges, each agency contributes its particular strengths in order to address the very broad issues raised by concerns about global change.

One section of the congressionally approved Act indicated that the USGCRP

> shall prepare and submit to the president and the congress an assessment which:
>
> 1. integrates, evaluates, and interprets the findings of the program and discusses the scientific uncertainties associated with such findings;
> 2. analyzes the effects of global change on the natural environment, agriculture, energy production and use, land and water resources, transportation, human health and welfare, human social systems, and biological diversity; and
> 3. analyzes current trends in global change, both human-induced and natural, and projects major trends for the subsequent 25 to 100 years.

Fulfilling this mandate for the issue of potential climate change has taken several forms. At the international level, the USGCRP coordinates US participation in the assessments of the Intergovernmental Panel on Climate Change (IPCC). The IPCC assessments in 1990, 1996, and 2001 have, at the global and continental scales, carefully reviewed the scientific literature concerning climate change, its potential consequences, and options for mitigation. With the IPCC finding in 1996 that human activities were having a discernible in uence on the global climate, the USGCRP undertook a national level assessment intended to provide detail about potential consequences within the US.

Given this charge, an overall goal of the USGCRP has been to analyze and evaluate what is known about the potential consequences of climate variability and change for the US in the context of other pressures on the public, the environment, and the nation's resources. At the same time, assessment activities have been designed to initiate an active dialogue with those who would be affected by the potential consequences in order to help prepare them to deal with climate variability and change more effectively and to sharpen the research focus concerning coping options. Thus was born the National Assessment of the Potential Consequences of Climate Variability and Change for the United States, commonly called simply the *National Assessment*.

The US National Assessment has had three major components:

1. Regional analyses: Regional workshops and assessments were used to characterize the potential consequences of climate variability and change in regions spanning the US. A total of 20 workshops were held around the country during 1997 and 1998. Regions holding workshops included: New England and upstate New York; Metropolitan New York; Mid-Atlantic; Central and Southern Appalachians; Southeast; South Atlantic Coast and Caribbean; Gulf Coast; Great Lakes; Eastern Midwest; Northern Great Plains; Central Great Plains; Southern Great Plains; Rocky Mountain/Great Basin; Southwest-Rio Grande basin; Southwest-Colorado River basin; California; Pacific Northwest; Alaska; Pacific islands; and Native peoples and homelands. Based on the issues identified, most of the regions went on to prepare assessment reports that would address the issues identified in the workshops; the remaining regions are likely to be the subject of subsequent studies.
2. Sectoral analyses: Workshops and assessments were also organized to characterize the potential consequences of climate variability and change for five major sectors that cut across environmental, economic, and societal interests. The sectors included agriculture, forests, human health, water, and coastal areas and marine resources. As US assessment activities continue, the expectation is that examination of additional sectors such as transportation, energy, business and trade, wildlife, urban communities, international couplings, and many other sectoral perspectives will be needed to provide a more comprehensive perspective on US vulnerability.
3. National overview: A 13-member National Assessment Synthesis Team (NAST) was appointed as a federal advisory committee to provide the national overview. The NAST co-chairs were Dr Jerry Melillo of the Marine Biological Laboratory in Woods Hole, MA, Dr Tony Janetos of the World Resources Institute in Washington, DC, and Tom Karl of NOAA's National Climatic Data Center in Asheville, NC. The NAST was given responsibility for providing a national perspective that summarized and integrated the findings of the regional and sectoral studies and that then drew conclusions about the importance of the consequences of climate change and variability for the US. Both an overview report intended for decision makers and the public and a foundation report intended for experts were prepared (NAST, 2000, 2001). Among the innovations in the NAST report was use of a well-defined lexicon for conveying the relative level of likelihood and certainty of particular consequences. Thus, consequences were described as being either very likely, likely, possible, unlikely, or very unlikely in a consistent manner, based on the expert judgment of the NAST in evaluating the available literature and commissioned studies.

There were a number of unique organizational approaches used in the conduct of the assessment. First, responsibility for the National Assessment process was widely distributed and broadly inclusive, with each of the regional, sectoral, and synthesis activities being comprised of experts from universities, government agencies, public and private sector organizations, and from other stakeholder communities. Second, the assessment process was financially supported in a shared manner by the set of USGCRP

agencies, with each agency assuming responsibilities for those activities in which they had particular interests. Third, the assessment is viewed by the agencies as the start of a long-term engagement, bringing together the scientific community and those affected by climate change. Together, these steps have been designed to promote broad understanding of the issue and its importance and to encourage early recognition of the need to start adapting to climate change.

Conduct of the assessment focused on addressing issues of importance to people in particular places (the regions) and with particular interests (the sectors). Starting with the broad array of public concerns about the environment, the Assessment explored the degree to which existing and future variations and changes in climate might affect issues that people really care about. A short list of questions guided the process:

- What are the current environmental stresses and issues that form the backdrop for potential additional impacts of climate change?
- How might climate variability and change exacerbate or ameliorate existing problems? What new problems and issues might arise?
- What are the priority research and information needs that can better prepare the public and policy makers for reaching informed decisions related to climate variability and change?
- What coping options exist that can build resilience to current environmental stresses, and also possibly lessen the impacts of climate change?

In analyzing the potential consequences, the National Assessment teams utilized three approaches to generate plausible future climatic conditions. Historic data sets were assembled and used to evaluate the potential consequences of a reoccurrence of past variations in the climate, recognizing that there would also be an underlying warming trend. Computer-generated scenarios from the Canadian and Hadley (UK) climate modeling centers were used to provide a self-consistent set of plausible future conditions. These model scenarios spanned the range from warm/moist to hot/dry conditions that are typical of the results from wider set of climate models. Should these conditions occur, the US would experience about a $5-10\,^{\circ}F$ (about $3-6\,^{\circ}C$) warming and modest to strong precipitation increases across the US. Such changes would be equivalent to shifting warm climatic zones northward, such that, over the 21st century, the future climate of the central US would become like the current climate of the southern US. The third approach, only used in a few instances in this initial assessment phase, was to consider the amount of change that would significantly increase existing vulnerability by, for example, crossing a threshold or triggering a non-linearity. In addition to the various approaches to treating prospective climate variability and change, ecosystem models were used to generate prospective changes in vegetation cover, and socio-economic scenarios were generated to consider possible changes in population and economic activity.

The various regional and sectoral studies provided a diverse picture of potential consequences, with a mixture of beneficial and detrimental consequences. While potential adaptation measures were identified that could moderate adverse consequences for many societal activities, disruptions were found that were likely to affect the complex distribution of ecosystems across the US, with some types of rare ecosystems (e.g., alpine meadows, coral reefs) being particularly impacted because there was little potential for natural or assisted adaptation. Due to the likelihood of intensified evaporation and changes in the amounts and duration of mountain snowpack, water resources arose as an issue in regions across the US, from the dry regions of the southwest to the more water-rich regions of the Pacific Northwest. Timber and agricultural production were likely to increase due to carbon dioxide (CO_2) fertilization, but, should warming occur near the upper bounds of estimates, increased water stress and potential disruptive threats (e.g., fires for forests, pests for agriculture) could create significant vulnerability. Coastal and permafrost regions were found to be likely to suffer increasing stress, creating problems for buildings and other infrastructure. While the warmer, moister conditions would raise the heat index, reducing the quality of life, the health threat from such conditions is currently being reduced through increased reliance on air-conditioning. More generally, sustaining the health of the US population was found to require intensified attention to public health practices and community infrastructure and policies (e.g., building codes).

Quite clearly, many important questions and issues remain to be addressed. Given the initial nature and limited scope of the assessment, it was also recognized that uncertainties, including possible surprises, are also likely. For this reason, it is expected that assessment activities will become an ongoing part of the USGCRP.

Extensive information about the assessment, participants on the various assessment teams and groups, and links to the activities of the various regions and sectors are available over the Web at http://www.nacc.usgcrp.gov or by inquiry to the Global Change Research Information Office, PO Box 1000, 61 Route 9W, Palisades, NY 10964.

Dobříš European Environment Assessment Process

David Stanners
European Environment Agency, Copenhagen, Denmark

Dobr´s Castle near Prague in the Czech Republic was the location of the rst pan-European Environment Ministers conference held in June 1991. This conference, held under the auspices of the United Nations Economic Commission for Europe (UNECE), launched a new European cooperation in the eld of the environment and a pan-European assessment process to analyze for the rst time in the same format Europe's environment and its relationship and contribution to regional and global change. The assessment process has resulted in two reports to date: Europe's Environment: The Dobříš Assessment *(EEA, 1995, 1998). A third report had been requested for the 5th pan-European conference of Environment Ministers to be held in Kiev in 2003.*

Concerns about environmental changes in the countries of central and Eastern Europe were a common and sometimes a dominant theme in the struggles that led to the revolutionary changes that took place in Europe in the early 1990s. This, combined with a desire for greater European integration, was the catalyst for the Dobříš initiative which was proposed in 1990 by the then new Environment Minister of the Federal Government of Czechoslovakia, Josef Vavroušek (*see* Vavrousek, Josef, Volume 4) The initiative gave birth to the so-called Environment for Europe process which, following the Dobříš Castle conference, was followed by Ministerial Conferences in Lucerne (April, 1993), Sofia (October, 1995), Arhus (June, 1998) and Kiev (2003). In addition to the assessment process, the initiative has given birth to: an environmental action plan for Central and Eastern Europe, coordinated by the Organization for Economic Cooperation and Development (OECD); a pan-European biological and landscape diversity strategy, jointly coordinated by UNEP (United Nations Environment Programme) and the Council of Europe; and many diverse initiatives tackling different aspects of European environmental problems and global environmental change.

The environmental assessment process initiated at the Dobříš Castle Ministerial conference completely changed environmental reporting at the European level. For the first time Ministers directly requested an assessment to serve their purposes: to support the development of a comprehensive environmental program for Europe; to provide a sound basis for effective measures, strategies and policies; and to inform the public and raise awareness about environmental problems. The initiative dovetailed with and complemented developments in the European Union (EU) with the proposed establishment in 1990 of the European Environment Agency (EEA) (*see* EEA (European Environment Agency), Volume 4), a body designed to supply sound environmental information to support policy development in the EU to respond to and to help avert environmental changes.

Although environmental assessment at the EU level had EU environmental policy as a reference, no single common policy frame yet exists at the pan-European level against which the Dobříš European environment assessment process can refer. Thus, the aim of the first report was to set a comprehensive baseline and reference against which future progress, or deterioration, could be measured. Except for the global assessments of UNEP (see example, UNEP, 1992), hitherto, no comprehensive environmental assessment on such a regional scale had been attempted. This was partly due to the lack of a common policy framework, but it was also due to the lack of a common information base of comparable and reliable data on which to base the assessment. While there is much data available in the different countries, the coverage and scope vary enormously and there are many information gaps. Since an assessment was required and requested by the policy makers, a novel exercise began: assessing in parallel the environmental problems and the information required to make such an assessment, each helping to improve the other. This new dynamic approach to environmental assessment and reporting now underlies the technique followed by the EEA to produce the best available policy-relevant assessments for EU policy-making to address regional and global environmental change.

The European Commission accepted the task to produce the first report in cooperation with the UNECE, UNEP, OECD, the Council of Europe, the International Union for the Conservation of Nature (IUCN), the World Health Organisation (WHO) together with individual European countries. Produced by a task force set up by the European Commission to prepare the EEA, the report was published by the Agency itself in September 1995 and presented to the third environment Ministers conference held in Sofia, Bulgaria in October 1995.

Given the broad remit and lack of specific policy framework, the approach taken in this report was to assess the environment from four different angles: the environmental media; the pressures; human activities; and the environmental problems themselves. This approach provided a rich, interweaving set of perspectives with which to view the environment, and established the basis for many future assessments performed at different levels. It also set the way for the development of the DPSIR model of assessment now adopted by the EEA in its reporting on regional and global environmental change (D, driving forces; P, pressure; S, state; I, impacts; R, response) (*see* DPSIR (Driving Forces Pressures State Impacts Responses), Volume 4).

The second pan-European assessment was presented to the 4th Environment for Europe Ministerial conference held in Arhus, Denmark in June 1998. This conference requested the EEA to continue to measure progress with environmental problems in Europe and to report to the 5th conference to be held in Kiev in 2003 with a report based on indicators.

Eco-engineering to Promote Ecological Sustainability in China in an Era of Global Environmental Change

Rusong Wang
Chinese Academy of Sciences, Beijing, China

Rapid social, economic and environmental changes have taken place in China since its opening to the world and its transition from a planned to a market economy. Almost all kinds of environmental pollution found in early-industrialized countries, and ecological deterioration in poor developing countries, have emerged in China, exerting heavy impacts on people's health and local and regional life-support ecosystems.

Fortunately, a positive way - ecological engineering - has been found in China for alleviating the multiple ecosystem risks. Grounded in ancient human ecological philosophy, ecological engineering in China encourages an environmentally sound, economically productive, and systematically responsible way of alternative development. It uses the human ecosystem approach through ef - cient technology, appropriate institution and self-reliant technology. Here, the key is an integration of hardware (technological innovation and integrative design), software (institutional reform and system optimisation) and mindware (behavioural inducement and capacity building) (Wang and Yan, 1998).

The main characteristics of ecological engineering are to use:

- systematically coupled technology*: horizontal and vertical combination of various frontier and traditional technologies in one eco-complex, having the function of primary, secondary and tertiary production, and natural services;*
- ecologically adaptive technology*: closing the open loop of material metabolism at the ecosystem scale, and enhancing the structural and functional exibility so as to have high adaptability to the changing environment; and*
- economically efficient technology*: encouraging deeper processing and higher ef cient use of local resources, and decentralized and cost-effective wastes treatment so as to turn negative environmental impacts into positive economic bene t.*

Four kinds of ecological engineering are described below.

RURAL ECO-ENGINEERING: ECO-FARMING, ECO-AGRICULTURE, ECO-VILLAGE AND ECOPOLIS

Based on the carrying capacity of the local ecosystem, eco-farming in China encourages efficient use of material, energy and other eco-factors in farmland through intercropping, interplanting, multi-layer planting, water conservation, organic fertilizing and integrative pest management. This traditional technology has sustained Chinese agriculture for more than 5000 years. Unfortunately, it has been disappearing recently in some industrialising areas such as the Peal River Delta and the Yangtze Delta. Eco-technologies such as mulberry grove – fishpond, nightstool manure recycling and biogas systems used to be popular in

every household before the area became prosperous in the 1980s.

Based on ecological economics, eco-agriculture in China encourages competition, symbiosis and self-reliance among farming, forestry, husbandry, fishery and rural industry. There are more than 2000 eco-agricultural experimental villages or counties in China covering 123 000 km^2 and including 23.92 million people. By 1995, due to the development of this eco-agriculture, the annual increase of crop yield was over 15%, the yield per hectare increased by 10% compared with 1980, which is 4.5 and 9.2 times higher, respectively, than that of those counties without eco-agricultural development. The *per capita* income in the experimental areas was 12% higher on average than that of neighboring regions. It was 32% higher in 105 eco-agricultural experimental sites in Hubei province than the provincial average (Wang *et al.*, 1998).

Besides natural and economic symbiosis, rural sustainability has to rely on farmers' social behavior, local governance, rural–urban relationships and large-scale markets and the environment. The eco-household, eco-village and ecopolis are just this kind of development. There are more than 1000 eco-villages, 51 national eco-agricultural counties, a few eco-prefectures and one eco-province (Hainan Island) in China characterized by integrative development with many social, economic and environmental benefits.

ECO-INDUSTRY: CORN ENGINEERING IN ZHAODONG CITY

Corn industrial engineering was initiated in Zhaodong in 1996, a county in Heilongjiang province with a yield of more than two million tons of corn annually. This approach combines agriculture, industry and community development into an integrated system. It consists of four parts: corn processing with zero emission engineering; stalk engineering for forage, fertilizer and fuel engineering; comprehensive use of corn cobs engineering; and roots and residues recycling. The production chain of maize processing is prolonged, and wastes are used for producing furfural and xylose alcohol. Maize stalks are used to produce fodder for livestock, biodegradable plastics and other industrial materials. Corn roots are treated physically and biologically to fertilize cropland. Suspended protein and carbohydrates are retrieved from the wastewater with high chemical oxygen demand, which is then used for aquaculture and irrigation. Cow and pig manure is used to produce biogas. The biogas slurry is processed for pig and fish feeds. The solid wastes are used for culturing edible fungus and earthworm breeding. The residue and detritus from the earthworm beds, together with livestock and poultry manure, are used to fertilize maize fields. The liquid waste residue from biogas fermentation is a kind of eco-pesticide after being processed. In this way, starting from a small corn our mill, 17 factories for conversion and utilization of maize have been constructed, and the total production has increased by 110 times in four years while realizing clean production. This eco-industry is spontaneously initiated by enterprises rather than the academic world, and its main gain is economic but it also has ecological benefits (Lu *et al.*, 1998).

ECO-SETTLEMENT: ECOLOGICALLY INTELLIGENT CONSTRUCTION IN JINGHUA CITY

The public toilet in most Chinese cities is dirty, ugly and stinking. But in Jinghua, a middle size city in Zhejiang province with 300 000 habitants, the toilet is a kind of green, clean and productive house with self-purification, production and maintenance, called an eco-toilet. In fact, the eco-toilet is only one kind of an eco-building being developed in this town since the 1990s. Compared with normal building, an eco-building is a kind of ecologically intelligent building characterized by:

- decentralized waste treatment and regeneration;
- water conservation and recycling;
- wall and roof greening to restore the ecological service and production function of the occupied land;
- renewable energy exploitation such as solar and bio-gas use;
- eco-material use based on local alternative resources;
- eco-healthy indoor building and decorative materials;
- well insulated structure; and
- eco-compatible landscape design to embody Chinese Feng-Shui (wind and water) and man and nature in one principles.

A demonstration area of more than 30 000 m^2 of eco-buildings has been constructed in the town since the 1980s for residential, business, public and civil service use.

All organic wastes in these buildings go to an underground bio-gas pond, the roof is covered by a garden or a solar energy collection system. The eco-roof and green wall have significant benefits of thermal insulation, air freshening, sanitation improvement, economic products and reduced load on the municipal sewage system. The waste water is cleaned and reused for gardening and partly discharged, meeting the national water discharge standard of grade 2–3. The indoor temperature of the eco-building is 3 °C higher in winter and 3 °C lower in summer than that of a normal building. Furthermore, greening of the roof has restored the ecosystem capacity of 70–128% of the built-up areas on average. It is indeed possible to recover the ecological service and production

function of the land occupied by the building (Yu and Liu, 2001).

URBAN-RURAL ECO-SERVICE: GUANGHAN PILOT ECOLOGICAL ENGINEERING FOR MUNICIPAL SOLID WASTES (MSW) RECYCLING

MSW treatment is an urgent issue faced by almost all cities in China. Around half a million tons of household garbage is currently produced in Chinese cities and towns every day, most of which is simply dumped into the suburbs, causing severe water, air and soil pollution, land degradation, and human health problems in many regions. To search for a feasible way for MSW recycling, a pilot ecological engineering has been designed and implemented in Guanghan, a small city in Sichuan province with 90 000 residents producing 100 tons of MSW day$^{\bullet}$ ^{1}. It aims at waste reduction (to encourage waste marketing, residue-free agro-goods for sale, packing control, residue reduction, classified collection, etc.), disinfection (cleaner collection, toxicants separation, bacteria sterilization, sanitary landfill, water recycling, air quality control), regeneration (paper, glass, plastics, iron, steel, organic matter, heat generation), industrialization (mechanical industry for MSW, eco-fertilizer industry from MSW, crop residues and human and animal excrements, eco-industry of fully recycling production) and systematisation (planning and design, legislation and policy, monitoring and supervision, capacity building and institutional reform).

The municipal government enacted a series of regulations and legislation in institutional reform and integrated management for MSW. The sole responsibility of government for MSW has been changed to responsibility-sharing among policy makers, private enterprise and the public, where local government is responsible only for policy making and institutional reform, private companies are given incentives to earn profits from MSW through eco-tech, citizens are responsible for voluntarily reducing, separating, recycling, monitoring and inspecting wastes, and scientists and technicians are responsible for providing ecologically sound methodologies and technology. Economic incentive measures have been introduced to strengthen the responsibility of society. After a 2-year pilot study, the Shan-Feng company began to make a profit. The environmentally sound composting fertilizer that was produced not only met the demand for green food production and garbage disposal, but also partly solved the relevant environmental problems of livestock wastes, crop residues and human excrements. And the most important finding is the new sense of self-reliance that the MSW problem can be solved through ecological engineering. A national MSW conference was held in Guanghan in 1999 to disseminate the results to other counties (Hu *et al.*, 1998).

MINK (Missouri, Iowa, Nebraska, Kansas) Study

Norman J Rosenberg

Pacific Northwest National Laboratory, Washington, DC, USA

There is concern that the increasing concentrations of CO_2, CH_4, N_2O and other radiatively active trace gases will lead to global warming and climate change. How global climate change will play out in speci c regions of the world cannot yet be predicted with con dence. However, a number of the general circulation models (GCMs) used to project climate change agree that the mid-continental portions of Northern Hemisphere continents will become warmer and drier. For this reason, a group of researchers at Resources for the Future and the Paci c Northwest National Laboratory undertook to study the implications of a change to a warmer- drier climate on the total economy of a portion of the central United States - Missouri, Iowa, Nebraska and Kansas (hereafter the MINK region or MINK).

The MINK region (Figure 1) is primarily agricultural except on the Ozark Plateau in southeast Missouri where forestry is practiced and in the Nebraska Sandhills, used primarily for grazing. The economy of the region is more dependent on agriculture than any other in the country.

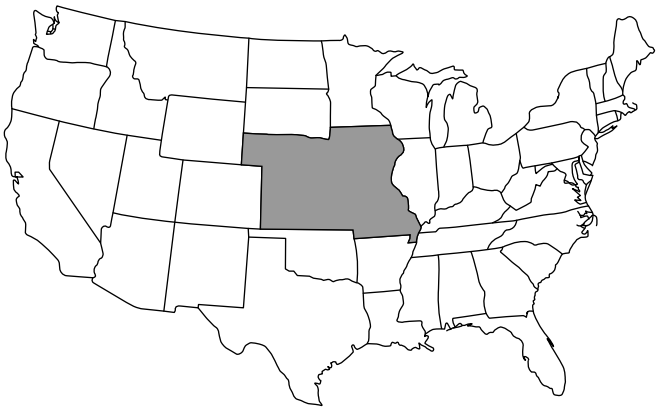

Figure 1 The MINK region (Missouri, Iowa, Nebraska and Kansas) of the central United States

The major rivers in MINK – the Missouri, Arkansas-White-Red, upper and lower Mississippi – support irrigation and navigation and provide hydropower. The MINK study focused on agriculture, forestry and water resources. Implications for the energy sector were also analyzed. Details of the study can be found in Rosenberg (1993).

Rather than use GCM projections of climate change, the researchers developed a surrogate scenario based on weather records for the subject region for the period 1931–1940 – the dirty thirties'. The most severe and protracted drought in the recorded history of the United States was experienced in this decade. These records and records for the period 1951–1980 (by definition of the World Meteorological Organization the normal climate at the time of the study – 1988–1992) were used to drive mathematical models that simulate crop and forest productivity under the normal (current) and 1930s climatic conditions. It was necessary in these simulations to consider that the rising atmospheric carbon dioxide (CO_2) concentrations that drive greenhouse warming are also of direct benefit to plant growth. Rates of photosynthesis increase and water use decreases in response to a so-called CO_2 fertilization effect. A different approach was taken to estimate how rivers in the MINK region would fare under the more stressful climate of the 1930s. Stream flow in the 1930s was compared to that during the 1951–1980 period in 15 watersheds that were then and are still essentially unmanaged. Further, since measurable climate changes may be decades off in the future, the 1930s' climate (with and without CO_2 fertilization) was also imposed on the farms and forests as they might be in the year 2030 when greater regional and global populations will increase demand for food, wood products and water, and new production methods will have been deployed. Finally, the efficacy of adaptation to climate change was studied by comparing crop and forest productivity and river flows with and without attempts by farmer, forester and water manager to adjust to change.

Assuming no attempt is made to adapt, the models indicate that the 1930s climate would lower current yields of dryland corn, sorghum, and soybean by about 25% for the region as a whole; CO_2 fertilization would reduce these losses to between 13 and 17%. With CO_2 fertilization region-wide yields of dryland wheat were 10% higher than at present. Aggregate loss of crop yield for the region as a whole is only 4–5% if farmers make use of currently available methods for adaptation such as changing planting dates and using new adapted crop varieties. By 2030 anticipated technologies would raise today's crop yields by 70% or more, assuming no climate change. However, with the dirty thirties' climate imposed on 2030 yields of these more productive crops would still be subject to losses of about 25%. If CO_2 fertilization were to take hold, these losses would be largely offset.

The economy of the region as a whole would not suffer greatly from imposition of the surrogate climate change, either today or in 2030. Allowing for sectoral adjustments to the new climate, the decline in regional income and production would likely not exceed 1–2%. But these aggregate regional estimates obscure the likelihood that certain sectors could be severely disrupted. Irrigation would not be sustainable in western Nebraska and Kansas and would shift to the more topographically varied eastern portions of the region. Long-term effects on forestry would be severe. With little potential for adaptation in the already marginal forests of the Ozark region, the models show that productivity would be lower still and many of the current species would vanish. Impacts on water resources would be severe, with current stream flow decreasing by 28% in the Missouri and upper Mississippi and 12% in the Arkansas-White-Red river basins. Water-based recreation would suffer and navigation on the Missouri would become uneconomic in these circumstances. The energy sector would not be greatly affected. Increased demand for air conditioning would be largely offset by reduced demand for space heating and crop drying.

MINK was the first study to consider the impacts of a climate change scenario on the total economy of a region and to draw policy guidance from its results. The effects on agriculture are most easily quantified (see above). Unless demand for biomass energy warrants investment in tree plantations, the only management that would be economically justified in the region's forests would be the harvest of dead and dying trees. Removal of subsidies for irrigation would preserve more water to sustain income-generating wildlife habitat, fisheries and water-based recreation. Diverting water from navigation for greater hydropower production would be not only a necessary adaptation but would also reduce the amount of fossil fuels consumed in the region. Maintenance of a

strong research establishment will be essential if the new technologies needed to permit adaptation are to be there when needed.

RAINS (Regional Air Pollution Information and Simulation)

The prototype of the Regional Air Pollution Information and Simulation (RAINS) model was developed at the International Institute for Applied Systems Analysis (IIASA) in Austria in 1984. The model has evolved considerably over the years and currently has two versions: one for Europe and one for Asia. The model contains modules for pollution generation (from industry, power sector, transport and agriculture), long range transport of air pollutants, and environmental effects of acidifying compounds.

RAINS is a tool for analyzing alternative strategies to reduce acidification, eutrophication and ground-level ozone in Europe. It combines a variety of information relevant for the development of cost-effective emission control strategies in Europe:

- projections of future economic, agricultural and energy development in 38 European countries;
- the present and future emissions of sulfur dioxide, NO_x, volatile organic compounds (VOC) and ammonia resulting from these activities;
- the options for reducing emissions and the costs of these measures;
- the atmospheric dispersion characteristics of sulfur and nitrogen compounds and the formation of ground-level ozone;
- the environmental sensitivities of ecosystems towards acidification, eutrophication and ground-level ozone.

RAINS integrates latest scientific findings, up-to-date databases and advanced systems analytical (optimization) tools.

As far as technically possible, the RAINS software package is operational in a standard PC environment and/or on the Internet. In early 2001 the following versions were publicly available:

1. PC version 7.2 (released early 1997) (http://www.iiasa.ac.at/• rains/index.html)
2. RAINS web version
   - RAINS PM Web Module giving access to particulate matter databases (http://www.iiasa.ac.at/• rains/index.html)
   - On-line ozone/acidification scenario analyses (http://www.iiasa.ac.at/• rains/index.html)
3. For Asia, the RAINS-Asia PC software (http://www.iiasa.ac.at/Research/TAP/rains_asia/docs/index.html)

Work is underway to transfer, as far as technically possible, the full RAINS model to the Internet and to enable permanent general access to up to date databases. Furthermore, RAINS will be extended to include fine particulate matter, its sources, abatement options, transport and effects.

The RAINS model is the outcome of a multi-year scientific effort of an interdisciplinary and international team of researchers at IIASA.

RAINS has been at the center of major international environmental negotiations. Twice it has been central to renegotiation of the Convention on Long-range Transboundary Air Pollution, the umbrella convention regarding air pollution across all Europe (*see* LRTAP (Convention on Long Range Trans-boundary Air Pollution), Volume 4). RAINS also underpins the European Union policy and directives on air pollution. Countries in Southeast Asia are turning to the model for help with their growing air pollution problems.

With some 900 copies of RAINS delivered to governments, private firms, academic institutions, and environmental non-governmental organizations (NGOs) in more than 50 countries on four continents, RAINS is one of the most successful integrated assessment tools yet devised.

The RAINS prototype model for Asia was developed in 1992 and is currently focused on sulfur dioxide. The RAINS-Asia model offers the opportunity to assess sulfur deposition and ecosystems protection levels resulting from different energy pathways and different emission control strategies. The costs of various control options are also provided.

Transboundary Water Resource Management: The Example of the Canada/US IJC (International Joint Commission)

A P Lino Grima
University of Toronto, Toronto, Canada

Over the last nine decades, the Canada- US IJC has established a reputation as a credible international model for dealing with transboundary water issues. The IJC was set up in 1912 under the provisions of the 1909 Boundary Waters Treaty. It consists of three members appointed by the US and three members appointed by Canada, all of whom are expected to act as members of the IJC rather than as appointees of the two signatories. Over the last decades the reports of the IJC have been unanimous and the members of the commissions have hardly ever voted along national lines.

The IJC has given a lot of attention to Great Lakes water quality and quantity (Ashworth, 1986; Weller, 1990) and its work on the Great Lakes best exemplifies both its strengths and weaknesses. Because of the IJC's responsibilities for the Great Lakes, the IJC has a Windsor Great Lakes office in addition to the two offices in the national capitals. However, its responsibilities extend to the whole Canada-US border. The IJC has two functions. First, it has quasi-judicial powers to approve applications for the use or diversion of boundary waters that would affect their ow or level. It is a measure of the success of this international body (and of the independence of its members over the years) that the decisions on these applications have never been challenged in court. Second, the IJC may receive a reference, i.e., a request to study and report on an issue and make recommendations for its resolution. The IJC has dealt with numerous references, the first one in 1912, regarding the high level of bacterial pollution in the Great Lakes. Other issues that the IJC has studied as references over the last nine decades include the Trail Smelter air pollution issue, the Columbia River, the allocation of Niagara hydroelectric power, the ooding of the Red River in Manitoba and North Dakota and the pollution from land-based activities in the Great Lakes Basin. It should be noted that on several issues (e.g., Columbia River, Niagara power), the two governments signed a new treaty rather than adding new responsibilities to the IJC. There have been several references about the uctuating levels of the Great Lakes (Grima, 1993; Grima and Wilson-Hodges, 1977) and most recently the two federal governments have asked the IJC to study and make recommendations for protecting the integrity of the boundary waters in the face of expected threats from climate warming and bulk exports of water (IJC, 1999). These references have given the IJC a well-deserved reputation for putting together a common factual and technical base (Spencer *et al.*, 1981). This is an essential first step for moderating debate among the competing publics and also of providing direction for action by the US and Canadian governments. In order to discharge this function, the IJC requires technical information about the hydrological–chemical–biological–economic system and information about what the various publics want.

One of the most innovative features of the IJC (especially since its rules of operation were established 90 years ago!) is its obligation to consult the public about its references. The IJC notifies the public at the start of its reference in order that interested groups of individuals may submit opinions and information to the IJC or the technical study group set up by the IJC to conduct an investigation. At the end of study the IJC shall hold public hearings to allow the public to respond to the findings of the study and the recommendations. In this respect, the IJC has been a pioneer in establishing public participation in the policy making process! (Grima and Mason, 1983).

One of the major successes of the IJC was the signing of the Canada-US Great Lakes Water Quality Agreement (GLWQA) by President Nixon and Prime Minister Trudeau, in 1972, when the most pressing and visible problem was the elevated concentrations of phosphates and consequent proliferation of algae. The GLWQA is the most significant instrument for protecting and restoring the integrity of the Great Lakes ecosystems. The phosphorus loads were lowered across the basin especially by discontinuing the use of phosphate detergents and improvements in point sources of nutrient loading, particularly the sewage treatment plants across the Great Lakes Basin. For example, the total phosphorus load from municipal sources to Lake Erie was reduced from about 15 000 ton year$^{\bullet 1}$, in 1972, to about 2500 ton year$^{\bullet 1}$ by 1983 (Colborn *et al.*, 1990). On the other hand much less progress has been reported with respect to non-point (i.e., diffuse) sources such as agricultural runoff and the clearing of ground cover during the building phase of housing subdivisions. The reduction in eutrophication that originated largely in phosphate-rich detergents and the consequent restoration of water quality in the Great Lakes Basin is an example of successful environmental management and international cooperation.

The GLWQA was revised in 1978, to re ect the less visible pollution from the use of chlorine-based chemicals such as dioxin and other organochlorines (Colborn *et al.*, 1996). Among the principles included in the agreement, one could note the use of the ecosystem approach

(*see* Ecosystem Approach, Volume 2), and zero discharge of persistent toxic substances. The GLWQA was further revised in 1987 (US and Canada, 1987). The 1987 revision of the agreement commits the two governments to develop *remedial action plans* (RAPs) for the 43 *areas of concern* (AOC) (since reduced to 42 with the cleanup and delisting of the Collingwood, Ontario, AOCs) and also lakewide management plans for each of the five Great lakes. The RAPs were to be developed with public advisory committees (PAC) (called CAG or citizen advisory groups in the US), which were set up as stakeholder groups for each of the AOCs. In addition, the RAPs shall embody an ecosystem approach to restoring and protecting the beneficial uses of the water in each AOC. The ecosystem approach refers to the comprehensive treatment of issues such as urban runoff and industrial discharges as well as to the involvement of a wide array of agencies and institutions at the local, state/provincial and federal level, private companies and non-governmental organizations (NGO). The RAP program is significant because cleaning up the most polluted parts of the Great Lakes is the necessary first step to demonstrate the commitment of the governments of the US and Canada to achieve the objectives of the GLWQA. The narrow objectives of the RAPs is to restore the beneficial uses of the 43 AOCs. These beneficial uses may be summarized as drinkable, fishable and swimmable waters. The beneficial uses have been reduced by at least 14 specified impairments including beach closings to swimming, taste and odor problems in drinking water and reproductive problems in birds, mammals and fish.

On the 10th anniversary of the formal start of the RAP process, (which also coincided with the 25th anniversary of the signing of the GLWQA), the Great Lakes Water Quality Board (WQB) of the IJC published its assessment of the progress of the RAPs (WQB, 1997). They selected 21 examples of successful RAPs that included the delisting of Collingwood, Ontario as an AOC, and considerable expenditures ($1 billion) in the Rouge River, MI, to reduce combined sewer over ows. The other 19 examples record much more modest accomplishments and there are another 21 RAPs that were not included at all in this list of selected examples of successful RAPs! The WQB's assessment also records the budget cutbacks and reduced support for the RAPs and the associated public advisory committees. Other observers, such as the International Association of Great Lakes Research (1997), while describing the RAPs as an unprecedented collaboration of international significance, also emphasize that reduced funding levels and changing government priorities place the process in serious jeopardy. The pre-eminent NGO in the region, Great Lakes United (1997), is even harsher in its assessment. Its statement points out that the major shortcomings are the removal of funds, particularly in Ontario and the fact that the RAPs have not been incorporated into existing institutional planning frameworks, which one would expect in a comprehensive ecosystem approach. (See also the more balanced set of comments by four academics in the same commentary). The cheerleading stance of the WQB is expected since the members of the WQB are also the administrators in the federal, state and provincial agencies that have to make the RAP process work! In addition, as the WQB assessment quite correctly points out, greater emphasis should be placed on celebrating and marketing successes achieved over the last 10 years in order to maintain public interest in the RAPs and build a constituency to increase pressure for restoring budgets.

One of the reasons for revising the GLWQA, in 1978, was the realization that one very important Great Lakes issue had not been addressed in 1972, viz., the high levels of organochlorines and heavy metals in the ecosystem and the consequent effects of exposure to these synthetic chemicals on humans and wildlife. Deformities such as crossed bills and unhatched eggs in fish-eating birds, reduced mink populations, lesions in lake trout and other top aquatic predators are ascribed to these persistent pollutants which are found in concentrations of 1 parts per billion (ppb) or so in the water but which eventually bio-accumulate and bio-magnify as they are ingested up the food chain (Colborn *et al.*, 1990). In addition to being suspected carcinogens, these persistent toxins also disrupt the endocrines system in wildlife (i.e., they disrupt embryonic development even in healthy adults) (Colborn *et al.*, 1996). The IJC and the Great Lakes policy makers have not registered much progress in controlling these chlorine-based chemicals, which include pesticides, polychlorinated biphenyls (PCB), dioxins and furans. And progress is likely to be slow since these chlorine-based chemicals are used in numerous items in every day use such as water pipes, building materials, plastic containers, car parts and so on. In addition to the continuing use of such chemicals, there are large quantities buried in sediments and landfills (the most notorious example was the Love Canal), in most of the AOCs. The RAPs are supposed to be dealing with these reservoirs of pollution. However, the RAPs themselves are at a crossroad, perhaps in crisis, largely because of budget cutbacks and also because they lack an appropriate administrative structure for developing and implementing a clean-up plan.

Indeed, the RAPs could serve as a good example of the strengths and weaknesses of the IJC as a whole. The strengths of the IJC include its quasi-judicial tasks in dealing with water level issues; it acts as a fact-finder when it is dealing with references for studies of complex issues; it brings together teams of international experts and provides an international perspective to bi-national issues; it has gained respect because of its reputation for impartiality; and it allows for regular meetings of

middle and senior managers. Its weaknesses stem from its utter dependence on the agendas and priorities of the two federal governments; for its operations it depends on the two governments for budget and personnel, which reinforces its fragility as an advisory body. The use of agency personnel creates a situation where the experts who advise the IJC are the same administrators of the agencies that are responsible for the state-of-the-lakes in the first place. It is most unlikely that the IJC's functions will be expanded beyond its present considerable powers to study, recommend, cajole and persuade. It is almost certain that the IJC will continue to play a lead role in the management of water resources shared by two friendly nations and therefore will continue to stand out as a successful example of international environment management.

Preface to the Encyclopedia of Global Environmental Change

THE ENVIRONMENT

The word *environment*, whose dictionary meaning is simply that which surrounds, has in the last few decades become a buzzword , encompassing an exceedingly diverse array of elements and social issues. Taking the original meaning as a point of departure, it is clear that we humans depend totally on the environment provided by planet Earth for the food we eat, the water we drink, and the air we breathe. Thus changes in this environment must be of vital concern. Will Earth continue to sustain humans in a way that also encourages the ourishing of the other living things with whom we share the planet? This question has loomed ever larger as it has become more evident that human activities have been inducing major changes in all of the compartments of the global environment. We have converted forests and savannas to farms and cities; we have exhumed ancient treasures of fuels and minerals; we have used the rivers and winds as convenient sewers; and we have released entirely new chemical compounds and organisms into the environment. In the 1960s, the scienti c community began to use the word *environment* in this new non-specialist sense. Soon too, Departments of the Environment were created by many governments, and new scienti c journals began publication while others were re-named. For example, the *International Journal of Air Pollution* became *Atmospheric Environment*! In the ensuing decades, the world community has come to see the environment in many different ways, as a life-support system, as a fragile sphere hanging in space, as a problem, a threat and a home.

GLOBAL ENVIRONMENTAL CHANGE

A broader and deeper understanding of the global aspects of environmental concerns emerged in the 1970s and 1980s, and a new phrase *global environmental change* acquired popular currency. Paleoresearch had revealed that environmental change was far from new, and by no means the sole result of the actions of heedless humans. Since the planet s formation, virtually every element of its environment has been undergoing massive changes on all space and time scales. Oxygen waxed and carbon dioxide waned in the atmosphere. Continents moved about the planet s surface like scum on a soup kettle. Great ice sheets grew and shrank. Above all, the force of life (the biosphere) emerged as a dominant driver of planetary change.

However, another vital insight began to emerge about 1980: the inescapably interlinked nature of these many environmental changes. On the very longest time scales, continental drift moved lands into different climates but also changed the climate of the globe itself. Photosynthetic life changed the atmosphere but also made possible more advanced life forms that could take advantage of the new environment. On shorter time scales, atmosphere and ocean often interact to produce the massive changes in the Southern Paci c that we term El Niño and La Niña, whose consequences extend across the planet, and profoundly affect even our socioeconomic systems. Indeed, we have come to realize that human-induced perturbations in the environment are becoming increasingly large, and are potentially coming to dominate the natural workings of the complex and interdependent global system that sustains life on Earth. Humans and their global environment are no longer independent; they are ever-increasingly becoming interdependent components of a single global system.

Thus, the term *global environmental change* has come to encompass a full range of globally signi cant issues relating to both natural and human-induced changes in Earth s environment, as well as their socioeconomic drivers. This implicitly includes concerns for the capacity of the Earth to sustain life that have motivated the development of studies of global change and sustainable development in the last few decades. Analyses of global environmental change therefore demand input from the social sciences as well as the natural sciences (and indeed also from the engineering and health sciences) necessitating an inescapably interdisciplinary approach.

Scientists from many disciplines have been attracted to this growing eld of global environmental change. This is particularly noticeable in the biological sciences through the encouragement of IGBP (International Geosphere Biosphere Programme), which invites ecologists to expand their eld of vision from the plot and landscape scales to the regional, continental and global ones, and to interact with scientists from other disciplines in exploring environmental change at these larger scales. Indeed this trend has encouraged publishers and scienti c societies to introduce new journal titles, and these publications from all accounts appear to be ourishing.

At the same time, human social, economic, and cultural systems are rapidly changing under the in uence of growing globalization. In the economic sphere, for example, today s discourse centers on multinational corporations, the Global

Economy, and the Globalization of Trade. Thus, the agendas of most of the physical, life, and social sciences increasingly focus on global-scale changes.

THE EVER-CHANGING ENVIRONMENT

Since the launching of Earth-viewing satellites, we have been able to see a constantly updated moving picture of our planet. Great weather systems sweep around the globe, waves of green and brown ebb and flow over the continents with the seasons, as do white waves of ice and snow. Nevertheless, a remarkable feature of the Earth system has been its relative stability. Since the dawn of life, the planet's environment has remained within a range of conditions that has supported life. Moreover, with some notable and perhaps cautionary exceptions, changes from year to year, decade to decade, millennium to millennium, have been modest, particularly during the last 10 000 years. Many features of human society exhibit similar behavior. Civilizations and cultures evolve slowly for the most part in response to environmental, economic, and social driving forces over their long lives. Great cities like Rome endure through the ages. A citizen of ancient Babylon probably would have little difficulty understanding the politics of modern Toronto.

But today we appear to be entering an era of change unprecedented since Babylon was a cluster of mud huts. There are many reasons to believe that changes greater than humankind has experienced in its history are in progress and are likely to accelerate.

Virtually every measure of human society – numbers of people and automobiles, airplanes, energy consumption, generation of waste – is increasing exponentially. While the values of a few indicators are leveling off, the magnitudes of annual increases of others remain immense.

Major changes are becoming evident in many critical elements of the environment – increasing carbon dioxide concentrations, stratospheric ozone depletion (not to mention the stratospheric Antarctic ozone hole and the possibility of a similar Arctic event), rising sea level, declining productivity of soils, widespread collapses of fisheries, dramatic declines in biodiversity, destruction of tropical forests, etc. Within living memory, the countryside around large cities has been swallowed up by suburban developments and highways. Humans are stepping on the gas pedal of the planet's environment, and perhaps recklessly breaking the survivable speed limit of global change.

Paleoclimatological studies have shown that the stable environment that we take for granted has not always prevailed. Indeed, the relatively brief period in which human civilization has developed is somewhat unusual in its equable stability. Neolithic hunters in Europe some 13 000 years ago saw their climate shift from temperate to glacial in a single short lifetime. The evolution of human society is punctuated by wars, pestilence, and technological revolutions. Major – perhaps even catastrophic – change could occur in the future, because we know it has occurred in the past.

Rapidly advancing understanding of both natural and human systems – and above all the ability to translate that understanding into quantitative models – has enabled us to explore the future of our global society and its global climate with unprecedented realism. Although prediction of the single future path that we will follow is inherently unpredictable, it is possible to map a broad range of future environmental trajectories that we might take, each completely consistent with our understanding of how the system works. Such scenario-building exercises amply confirm our concerns that the changes of the 21st Century could be far greater than experienced in the last several millennia. Business-as-usual for human society appears to imply business-as-highly-unusual for the global environment.

THE INTERLOCKING BIOGEOPHYSICAL – SOCIOECONOMIC SYSTEMS

Recognition came in the 1970s that many of the environmental issues are inter-connected through the biogeochemical cycling of trace substances, especially carbon, sulfur, nitrogen and phosphorus. In fact, in a prescient statement on the main environmental research priority of the 1980s, Mostafa Tolba (then Executive Director of the United Nations Environment Programme) and Gilbert White (then President of the Scientific Committee on Problems of the Environment) drew the attention of both the scientific and the science-policy communities to the need to understand the major global biogeochemical cycles in order to maintain the global life support systems in a healthy state (Tolba and White, 1979). Quoting from that statement,

> We draw attention to the fundamental scientific importance of understanding the biogeochemical cycles which link and unify the major chemical and biological processes of the Earth's surface and atmosphere. The results will have practical significance for all of us who inhabit an Earth with limited resources and who, by our actions, increasingly affect the quality of the human environment.

So it is that many of the global environmental issues – acid rain, stratospheric ozone depletion, climate change, nitrogen over-fertilization – are inter-related through the global biogeochemical cycles.

One of the interesting results of the study of the Earth's history has been the discovery of the global teleconnections of the Earth system, with some major climatic shifts occurring simultaneously in the two hemispheres. In an analogous way, there has been recognition for a long time that human social, economic, and cultural systems are globally inter-related. That these are connected in turn to the

Earth system was implicitly recognized as early as the 1972 Stockholm Conference on the Human Environment.

To manage the human responses to this enormously varied but at least moderately coupled world system in an era of increasing global change through the diverse array of local, national and international organizations is indeed a daunting challenge. An essential first step is to describe past and present states, then to explain the various phenomena observed, and finally to develop predictive models (or at least a range of scenarios) describing the future behavior of this total Socioeconomic–Cultural–Environmental system. In this process, environmental scientists must learn how to assimilate better the new information constantly being received, although uncertainties, often large, will continue to exist. Within this mix, rational and effective policies must be developed that will balance the risks and costs of global environmental change in an adaptive way. Only then will we be able to even formulate, much less start to implement, rational and effective policies that cope effectively with global change. The prospect of change tempts us to think in terms of winners and losers. However, such analyses often do not play out in simple ways. For example, a modest increase in rainfall would cause farmers to rejoice while vacationers would despair. However, greater farm production can lead to lower commodity prices, thereby reducing farm incomes while making vacation food purchases less expensive. Human society is pretty well adapted to the present environment, so change is necessarily a challenge.

In the longer-term, much depends on the ability of societies to respond, to adapt. Societies will differ in the resources – natural, human, and technological – that are available to them. They will also differ in terms of the values and priorities they attach to physical, social, and environmental goals, and in the social and political mechanisms that they employ to seek these goals. These differences in the human world of generations yet unborn may be as great – and as significant – as the changes in the global environment. A major challenge for our times is to develop frameworks for understanding complex interdisciplinary issues of this complexity.

No discussion of change and the future can be complete without consideration of risk. Projections of the future, however imaginative or soundly based, necessarily center on plausible, surprise-free scenarios – population will increase, economies will advance, climate will change – all typically slowly and smoothly. However, such projections made at the beginning of the 20th Century would have missed two World Wars, the automobile, aviation, space travel, television, and McDonald's in Beijing. By definition, genuine surprises cannot be predicted. However, an understanding of the impacts of past surprises may help us to make our society and our world somewhat more robust in the face of the unknown surprises that await us.

THE HUMAN DIMENSIONS OF GLOBAL ENVIRONMENTAL CHANGE

The human dimension of global change has been defined as the ways in which individuals and societies contribute to global environmental change, are influenced by it, and adapt to it. Many empirical studies have been undertaken that describe human activities in physical terms, based on various kinds of indicators. Rates of deforestation, urbanization, and changing levels of emissions of greenhouse gases are only some measurable contributors to environmental change. But the dynamics of human activities and global change are much more complex, and they reflect the complexities of the human–nature relationship.

While the sheer burden of human activity on the planet is important, we know that the major forces at work are human beings operating together through political systems, corporations, interest groups, and beliefs that sway whole peoples. These raise questions about the nature of choice, about the hopes, dreams, and frustrations that impel people forward, or block them. At the moment, for instance, the dream of the good life – which has been a critical element of every religious tradition in the world – is increasingly being defined in terms of material possessions and powerful images that are shown on global media. Can this particular version of human happiness be sustained on a limited planet? Some people say that it can; others say that it cannot.

The central questions about the role of human beings in global environmental change revolve around social, cultural, economic, ethical, and even religious issues. These are becoming more and more pressing, and more and more foundational as human beings deliberately or inadvertently modify more and more of the planet. It is also obvious that in this generation the modification of organisms and ecosystems may well extend to the modification of human beings themselves. Among the fundamental questions are: What motivates us towards saving or harming the environment? How do we see ourselves with regard to nature? What is our responsibility to this and future generations? Who do we think we are, and who would we like to become? Appropriately enough, Volume Five of this Encyclopedia wrestles, in many different voices, with these ultimate questions that remain intimately linked with the sweep of physical, chemical, biological, geographical, and institutional changes documented and discussed throughout the earlier four volumes.

The Brundtland philosophy urges us not to reduce options for future generations. Implementation of this idea is, however, difficult. For example, it often seems more compelling to alleviate current poverty than to protect the environment and renewable resources for future generations. Many scientists agree that new approaches are needed to meld the social with the natural sciences in the policy arena. Some of the new methodologies that go beyond the physical sciences

are described in Volumes Four and Five of this Encyclopedia, e.g., post-normal science, integrated environmental assessment, and the precautionary principle.

In a commentary in which he described the 21st Century as the century of the environment, Edward O. Wilson began by referring to the growing *consilience* (the interlocking of causal explanations across disciplines) so that the interfaces between disciplines become as important as the disciplines themselves. He then stated that this interlocking amongst the natural sciences will in the 21st Century also touch the borders of the social sciences and humanities. In the environmental context, environmental scientists in diverse specialities, including human ecology, are more precisely defining the arena in which that species arose, and those parts that must be sustained for human survival (Wilson, 1998).

This is a major challenge for environmental scientists. Already through DNA techniques, for example, it is possible to trace back connections amongst prehistoric peoples through the last Ice Age to modern times.

THIS *ENCYCLOPEDIA OF GLOBAL ENVIRONMENTAL CHANGE*

More than two million papers are published every year in science and medicine, a twentyfold increase since 1940 that taxes the resources of concerned citizens, scientists, university departments, research institutes and libraries. At the same time, many policy-motivated organizations find it difficult to draw together the necessary expertise for resolving the newly emerging environmental issues. The scientific literature relating to the environment is burgeoning. However, research syntheses are in general still scattered across a broad spectrum of journals and books, and information on global environmental change is not readily available in an inter-related way. In particular, it is quite uncommon for contributions from the natural sciences to appear in the same journal or workshop proceedings as contributions from the social sciences and the humanities.

This *Encyclopedia of Global Environmental Change* is a comprehensive and integrated reference in the broad area of global environmental change that will be conveniently accessible and productively usable by students, managers, administrators, legislators, and concerned citizens. The Encyclopedia consists of five volumes of interrelated material:

Volume 1 The Earth system: physical and chemical dimensions of global environmental change (Michael C MacCracken and John S Perry, editors)

Volume 2 The Earth system: biological and ecological dimensions of global environmental change (Harold A Mooney and Josep G Canadell, editors)

Volume 3 Causes and consequences of global environmental change (Ian Douglas, editor)

Volume 4 Responding to global environmental change (Mostafa K Tolba, editor)

Volume 5 Social and economic dimensions of global environmental change (Peter Timmerman, editor)

The first four volumes cover the broad issues of the science and politics of global environmental change. Volume Five adds an often understated but extremely important aspect, linking as it does, global environmental change to the socioeconomic, cultural and ethical dimensions of human societies. Here will be found a rich panoply of writings by people who are not natural scientists but who have thought deeply about the environment. It places global environmental change in a refreshing historical, sociological and cultural context. In many contributions, the time horizons of most interest are the last hundred and the next hundred years. However, some contributions dip backward millions of years. Throughout, the emphasis is upon the dynamics of the various processes discussed – how and why did they change? A second recurrent theme is the interconnection of processes and changes – What produces change? What is impacted by change? Finally, we attempt to deal even-handedly with natural and human-induced change, and with impacts on both the natural world and human society. From the numerous diverse articles in the Encyclopedia, we believe that the user can obtain a coherent picture of this complex and dynamic system of which we all are a part.

To assist in promoting this coherence, each volume begins with a group of extended essays on major topics that embrace the field covered in that volume. These are intended to provide an introduction to the topic, a convenient road map through cross-references for exploring the Encyclopedia. Then there follows, in alphabetical order, shorter articles on a variety of scientific topics, descriptions of scientific programs, definitions, acronyms, and biographies of leading contributors to the field – from Charles Darwin, through the Russian ecologist Vernadski, to the three most recent environmental Nobel Laureates – Crutzen, Rowland and Molina. Indeed, these definitions, biographies and acronym definitions are, we believe, a uniquely valuable feature of the Encyclopedia. In the case of acronyms of international organizations and programs, it is no exaggeration to state that a young environmental scientist requires not only a good understanding of science, but also a good knowledge of acronyms, if they are to follow the discussions taking place at many international meetings! Also included in the alphabetic listings are abundant cross-references to related topics in the same or other volumes.

The substantive scientific articles that comprise the meat of the Encyclopedia are original contributions by active scientists from around the world, and thus

represent authoritative and up-to-date summaries of the state of current knowledge, direct from the producers of this knowledge. A number of these articles break new ground in synthesizing and summarizing our understanding from novel viewpoints and in unconventional ways. Thus, readers will find a wide variety of styles and approaches within the articles, reflecting in a unique way the rich diversity of today's world science. The articles have also had the benefit of careful reviews, particularly by our Editors.

The scientific essays and some of the program descriptions begin with a few italicized paragraphs written for non-specialists. These are not intended to be abstracts of the paper to follow, but rather are aimed at providing the reader with an introduction into why the topic is important and where it fits into the broader aspects of global change – a kind of encouragement to read on. Reading on should not be too difficult a task, since most of the scientific essays are written at the level of journals such as *Scienti c American* and *AMBIO* that are intended for the non-specialist. The Encyclopedia will be a valuable source of information for everyone with a general interest or a need-to-know in the various environmental fields (the natural sciences, socio-economics, engineering, the health sciences, and policy analyses) particularly as they relate to global-scale environmental change, its drivers, and its consequences. It is also expected that among the audiences for each volume will be practitioners and researchers in the fields covered by the other four volumes. We believe that this rather unusual – indeed unique – Encyclopedia will be used in a variety of ways.

1. Some people will employ it simply as a convenient source of information on specific topics – What has been happening recently to the sea ice in the Arctic Ocean? Who was Roger Revelle? What is soil mineralization? What is ICSU or IGBP? What is the Kyoto Protocol? What is deep ecology?
2. Serious students in the environmental sciences may begin by reading one or all of the introductory essays, which present highly compressed crash courses in a range of central topics.
3. We believe that the substantive specialized articles that constitute the bodies of the volumes are productively and enjoyably readable in their own right.
4. Finally, a case has been made by one of the volume editors (Peter Timmerman) for encyclopedia browsing as an enjoyable and productive pastime (*see* Encyclopedias: Compendia of Global Knowledge, Volume 5).

We believe that these five volumes are in the tradition of the human aspiration towards the compilation of global knowledge that sparked the preparation of the first encyclopedias in the 18th Century.

Our Editors have had the benefit of a marvellous postgraduate education in the course of the Encyclopedia's evolution! We are immensely grateful to the many, many authors in our virtual university who have contributed their wisdom to this project.

ACKNOWLEDGMENT

Many helpful comments and draft paragraphs were received from the Volume Editors during the preparation of this Preface.

Preface to Volume Five

Volume Five is devoted to the social, political, economic, and spiritual dimensions of global environmental change, and as such represents a departure from the conventional focus on the purely physical aspects of global change. It highlights the profound shifts in human thinking and awareness that are required to wrap our minds around the advent of globalization, and our increasing ability to affect natural systems, sometimes to our own benefit, sometimes not. This powerful role cannot simply be captured by treating human beings as if they were another natural force. Social, cultural, and economic ideas and institutions shape the desires and hopes, the conflicts and resolutions of conflict that are central to the human dimension of global change. Yet, at the same time, human beings are incontestably part of nature – as other volumes in this Encyclopedia demonstrate. Volume Five overlaps with, and complements, these other volumes.

Because of the complex weave of interaction between humanity and the environment, this volume contains many essays and articles that are more in the realm of probes than fixed descriptions of their topics. Powerful words and powerful ideas, metaphors, myths, beliefs, images and artefacts – these are all vehicles for the creation and shaping of meaning among human beings. Topics covered include the great political and economic theories, the most influential views of nature from Plato to Rachel Carson, and the historic and literary seedbeds for the rise of environmental thought and practice in our time.

Of particular importance in this volume are the introductory essays from leading figures in the field, and special efforts have been made throughout to give space to alternative voices and ideas. Dialogue and diversity are essential to human development, and we hope that the reader is stimulated by this volume towards his or her own thoughtful response to the increasing responsibility for the future of the Earth that has come upon us in our time.

Among the voices that we are privileged to present in this volume, the Editors would like to single out that of Ester Boserup, whose pathbreaking work as a student of the social dynamics of technological change, and of the role of women in economic development, make her an exemplar of the kind of interdisciplinary thinker so often proclaimed as necessary, and so seldom found. She died before the Encyclopedia could go to press, but we would like to dedicate this volume to her memory.

Peter Timmerman
Editor of Volume Five

The Human Dimensions of Global Change

PETER TIMMERMAN

University of Toronto, Toronto, Canada

The central icon of the environmental movement is the earth hanging in space, that mysterious and unexpected cargo brought back from the voyages to the moon. *See* Figure 1 in **The Earth System**, Volume 1. It appears on bedroom walls, refrigerators, and annual reports by multinational food companies. Blue-green and spherical against the stark blackness of space, it speaks of all things natural, all things green, the vision of one earth, one world.

Yet, part of its paradox is that this environmental symbol was the result of the most advanced technological project in human history (at that time), whose roots are easily traceable to the challenge of the Cold War, the long-range missile projects beginning in World War II, the atomic bomb, the militarization of space, and even the elegant camera technology that enabled the pictures to be taken.

But the image is even more iconic and mysterious than that. At rst glance, it appears a lonely image the only home we have devoid of human reference points, at least at the distance of the moon. Yet a nagging question is: where are we in this picture? The easy answer is that we are in there somewhere, maybe waving, or drowning. The more intriguing answer is that we are the picture: that it took all of science and technology that is, all of the ability to provide a temporary earth in a plastic suit in deep space to keep a human alive and all of history, that is, not just evolution, but all the social and cultural reasons that would make a being turn around at a precise moment oating in space, pick out the earth from the surrounding darkness as something worth photographing, and then lift a camera to his eyes, focus, and take a picture with some purpose in mind.

The literary critic, Marshall McLuhan, made a typically prophetic remark in 1970, in an obscure inaugural piece in an early environmental magazine (since defunct):

> whereas the planet had been the ground for the human population as gure; since Sputnik, the planet has become gure and the satellite surround has become the new ground •••. Once it is contained within a human environment, Nature yields its primacy to art.

McLuhan here invokes the familiar image of the gure-ground reversal the faces that turn into vases, and back again; or the duck that ips into a rabbit and ducks back again to suggest that while up until the arrival of the image from space, human beings saw themselves as gures on a ground, the environment is now a mere gure on human grounds.

The gure-ground reversal suggests that this is a sudden perceptual shift; which may be the case, but its elements have been arriving for some time.

One early element can be found in the idea that the higher you go off the earth, the closer you approach the realm of God. This is obviously exhilarating, but it is also blasphemous and unsettling. An early source is the temptation of Jesus, who, after being baptized by John, goes into the wilderness where he is threatened by the devil. Among the trials he undergoes is that of the potential for total earthly power; and the devil takes him to the highest point of the world and shows it all to him before Jesus rejects it. Peaks are for falling off of, as well as for gaining perspective.

In later medieval literature, airborne journeys of a more lighthearted sort take to the skies, the hero drawn by geese or lifted up by air currents, or in a dream. Yet when Dante leaps off the earth and moves into the higher realms in *The Divine Comedy*, it is clear that this is unsettling. A later appearance of the earth from space, in Milton s *Paradise Lost* is ominously seen from the perspective of Satan, newly released from the prison of Hell, and ying around the universe looking for a new home away from home.

This Godlike stance, epitomized by the image of the earth from space, is, as literature suggests, powerful. The arrival of global maps and globes in the 16th century was part of the great surge of Western power that began with the age of discovery and has only intensi ed its reach in the age of the Internet. The ability to hold the world in our minds is the forerunner of the ability to hold it in our hands, and *vice versa*.

Today we continue the same process. Again, it was McLuhan who said that in the age of satellites there is no more wilderness. There is hardly anywhere on the earth where one can hide, for example, from cruise missiles that, guided by satellite, can drop on a designated square meter of ground. The Hubble telescope, of which we have heard so much, has sister scopes whose magnifying powers are turned in to gaze on the details of our lives. It is clear that the American Armed Forces believe that the next high ground for military superiority is the satellite surround. Evidence of this could be found during the Gulf War in 1991, when the first action of the Allied powers was to cut off access to international satellite pictures for the Iraqis, the result being that they were forced to fight essentially blind.

Another related element, contributing to the figure-ground reversal, is the gradual increase in humankind's influence over the physical systems of the planet. Other volumes in this encyclopedia highlight this encroachment, where human beings are creaming off and rearranging vast parts of the earth's primary production for our own purposes. Certainly human beings have affected large chunks of the earth's natural terrain before, but the ability to affect whole physical and chemical cycles of the planet surely represents a watershed (airshed, earthshed) in earth's history. Our fingers and fingerprints are now and will continue to be all over the genetic future of a myriad species. The ground plans in which they will figure are human influenced, human inspired.

THE HUMAN DIMENSION OF GLOBAL CHANGE

A volume of an encyclopedia on global environmental change that deals with the human dimension of global change is thus necessarily confronted with fundamental issues, of which the most fundamental remains: what does it mean to be human?

Tightly related questions, but more obviously tractable (though one need not get too carried away with tractability) are: what is the relationship between human meanings and goals, and the tools, such as science and technology, that we are using to make those meanings and meet those goals? What does the humanizing of the planet mean? Is it manageable, possible, agreeable, delightful, horrifying?

In 1996, the philosopher Thomas Nagel published a book called *The View From Nowhere* (Nagel, 1996), which describes in detail the stance which modern science wishes to take. Another philosopher, Hilary Putnam, actually refers to this stance as *God's Eye View* (Putnam, 1995). The earliest intimation of that stance may be Archimedes' famous remark, that if he were allowed to place his lever anywhere, he could move the world. This hints at the later stance, which is that the earth is not a privileged vantage point, and in fact there is no privileged vantage point. Science seeks (or sought) to eliminate all the effects and influences of special locations, investigators, etc., in favor of universal laws. This has been undermined – at least at the popular level – somewhat by the paradoxes of the observer and the observed at the quantum mechanical level of science; but the ethos remains intact.

The social critics (Max Horkheimer, Theodore Adorno, and others) of the Frankfurt School in the 1930s were among the first to worry about the possibility that the search for this particular kind of enlightenment – what we might call the universe lying spreadeagled on the dissecting table – was not itself neutral. They suggested that the rhetoric of expanding human knowledge was harnessed to a very powerful unexamined Puritanical drive towards a pure objective truth, in the face of which ordinary human experience would wither and die. They also suggested that there is a complex connection between what we could call objectivity and the treating of the world as if it were an object.

The experience of the Nazi years (which, among other things, led to the fleeing of the Frankfurt School to America), and the arrival of the atomic bomb and the Cold War, substantially undermined the claims of what has been called the *Enlightenment Project* or the *Age of Modernity* (*see* Enlightenment Project, Volume 5). The claim that reason and science could improve the lot of humankind became juxtaposed against the claim that it could also destroy humankind. It was not enough to say that evil is always possible, and reason and science could be misused; critics began to question if there was something unreasonable in the very framework of modernity.

The famous (or notorious) outcome of this was the arrival of *postmodernism* whose antagonism to modernity was described succinctly by the French philosopher, Jean-Francois Lyotard, as a suspicion of all grand narratives (Lyotard, 1984). These grand narratives included the spread of reason over the world, universal human rights, the redescription of the natural world in scientific terms, the increasing recasting of natural resources by technology, and globalization.

It is worth pointing out in this context that virtually all the international organizations and initiatives represented in this encyclopedia subscribe to the grand narrative tradition, simply because they were either generated in the 19th century explosion of scientific networks and societies; or in the post-World War II heyday of the United Nations.

Postmodernist thought is aligned to what is sometimes called *postnormal science* (*see* Post-normal Science, Volume 5), which is an expression of a similar form of skepticism about the rhetoric of neutral science. Postnormal science interrogates this rhetoric, but also examines the work practices of scientists, their worldview assumptions,

the agenda-setting devices (e.g., why are scientists looking at this particular part of the world and not another?) and their communities.

Rayner and Malone, in their overview essay for this volume, describe in detail a number of the tensions between the universalizing tendencies in the physical sciences and the less powerful (but often similarly universalizing) counter-strategies in the social sciences and the humanities (*see* Social Science and Global Environmental Change, Volume 5).

To report on some personal experience, it was while I was involved with the project to establish the International Human Dimensions of Global Change Programme in the late 1980s that the project leaders found themselves practically, as well as theoretically, faced with the implications of the split between the worldviews of the physical sciences and those of the social sciences and humanities. Roughly speaking, however, the main dividing line is not between the sciences and the social sciences; in fact, the dividing line is within the social sciences, between those social sciences whose practitioners see themselves engaged in some form of quasi-physical science enterprise, and those that see themselves engaged in (what for want of a better phrase) what could be called meanings and frameworks.

The practical implications of this were (and are) that models of global change generated by physical science institutions treat human beings as if they were another element in a diagram of boxes with wires. The output of certain social sciences – parts of physical geography, anthropology, demography, etc. – can fit reasonably congenially into these wiring diagrams. Social behavior, communications, politics, and so on, are marginalized or added on as rhetorical flourishes in the form of feedback loops. On the other side of the dividing line, other social scientists and humanists assault the whole enterprise, i.e., that it is a symptom of the global situation we are in (the rationalized objectification of the world) and not a solution. This kind of standoff has complicated efforts to create international research programs that could usefully integrate the natural and the social sciences.

THE RISE OF THE ENVIRONMENTAL MOVEMENT

Traditionally, histories of the environmental movement (especially in North America) begin with conservation efforts and egregious examples of early industrial pollution, and trace its evolution through the creation of national parks, the upsurge of interest in the 1960s through Rachel Carson's (1963) *Silent Spring*, and the arrival of environmental legislation in the 1970s and 1980s. This fits in with a progressive model of a set of problems, problems identified, an orderly political response, and so on.

In light of the above, however, I believe that a more powerful history links environmentalism to some central concerns of the Romantic movement in the late 18th century about the fundamental relationship between human beings and Nature, in particular the nature of Human Nature in a world increasingly subjected to human influence. Moreover, the most compelling parts of works like Rachel Carson's are not about this or that pesticide, but about threats to what could be called the fabric of life, i.e., threats.

As discussed more fully in Art and the Environment, Volume 5 and Literature and the Environment, Volume 5, the Romantic movement was driven by a desire to overturn and reconstruct what the artists, poets, and advanced political thinkers of the time believed to be an outmoded, and indeed repressively dead, cosmology. This cosmology – patriarchal, hierarchical, and rational (in the sense of a machine-like logic) – was increasingly being used to cage and tie down new expressions of human well-being. Because it was outmoded, it was like a snake skin or an exoskeleton that was too small – externally applied, not internally generated.

Among the metaphors applied to this cosmology were the mask and the machine. The mask – ultimately derived from the critique of civilization fomented by the French philosopher Jean-Jacques Rousseau – symbolized the hypocrisy and public demeanor of ancient powers, as well as the emerging urban populace alienated from those powers, and from each other. The opposite of the mask was the Man of transparent virtue, and part of the increasingly vicious theatre of the French Revolution (1789–1795) was the relentless stripping off of, first, the masks of rank and station, and then, the stripping off of the masks of personal life down to the bone.

The machine came to symbolize both the newfound energy that could stimulate a new world of wealth creation, but also the turning of people into creatures of the machine. The early Industrial Revolution appeared to be like the maw of some great creature, driving rural people away from their farms and villages, and into hideously polluted factories where they worked inexorably, hour after hour, day after day. The fact that incomes and life-expectancies began their also inexorable rise upward, and the uncomfortable fact that supposedly happy rural life before industrialization would not bear close examination, had less impact than the immediately obvious relationship between the dismantling of a seemingly organic world and the interim chaos that ensued. Capitalism turned everything into a resource for exploitation.

To the Romantic writers and poets – William Blake, Henry David Thoreau, Friedrich Schiller – Nature becomes many things in the wake of the extraordinary eruption of industrialization into the world. Most obviously, it becomes a refuge from the ills of modernizing life, which is one of the sources for the conservation and parks movement. Less

obviously, it becomes a kind of comrade, or surrogate-like human beings, Nature is under threat. Some social ecologists see this as a central thread in modern environmental politics. Another aspect of Nature is its presence in the world as an alternative system or structure to that being raised by human ingenuity. The fact that it has a creative autonomy of its own, and is supremely inventive and complex in its own right, challenges the arrogance of technological man.

For some people, Nature becomes an entry into a spiritual realm, and interestingly enough, it is critics like John Ruskin and poets like Gerard Manley Hopkins, who fasten on the intricate details of Nature's design as the entry way; and not, as earlier, on Nature as a grand symbol. In this, one can see the growing influence of natural science, initially on the Victorians, and later in the synthesis that would become the environmental movement.

However important this history may be, the real history of the modern environmental movement, to my mind, begins with Hiroshima, and is followed very quickly by the revelations about the Nazi death camps. It was these events that concentrated a growing unease about the capacity of human beings to destroy themselves, and perhaps the world around them. We can begin to see a change of tone in environmental writing (still nature writing) in the 1950s (Rachel Carson's first successes appeared then); and it is little remembered that the writing of *Silent Spring* coincided with the first great international grassroots environmental action to stop the above-ground testing of nuclear weapons. Part of what fueled that successful political activity was the unsettling prospect of having what had hitherto been seen as a most benign metaphor, mother's milk, poisoned; and poisoned at a distance. Carson's pesticide poisoning at a distance amplified and echoed that other concern.

These threats to the fabric of life – to the possibility that rents in the fabric might be caused by human ignorance – were (in my mind) the spiritual dynamic behind the environmental movement. In the 1970s, it went somewhat underground, as the nuts and bolts of environmental management took center stage. I say somewhat, because it could always be found, for example, in the concern for the potential loss of endangered species. But at various points, it has returned in full force to revitalize environmental activism. In the late 1980s, the prospect of a rent in the fabric of the sky – the ozone hole – regenerated a whole array of environmental actors and institutions. Similarly, if more slowly, the prospect of irreversible climate change has begun to concentrate the minds of many activists.

The current activist environmental movement – in part because of the political dynamic associated with global environmental issues (symbolized by the Rio Earth Summit in 1992) – appears to be more inclined to return to the question of the role of modern industrialization and its technological imperatives. Globalization as a phenomenon is becoming widely seen as the interim step towards the ultimate transformation of the Earth into a human enterprise. Since multinational corporations and the rhetoric of global free trade are propelling much of this, environmentalists have begun making more and more sophisticated critiques of mainstream economics.

ECONOMICS AND GLOBAL CHANGE

A central fact about contemporary life is that globalization is rooted in a range of theories and practices that derive from economics. This is contested by those who would prioritize political structures such as the nation state, or strategies of imperialism, or even social or legal or philosophical forces deriving from the spread of Western models of individualism across the globe. Nevertheless, if one sees in economics a complex web of all of these, ultimately justified by an almost religious belief in the virtues of the market system whose every whim needs to be tended, then its strength as a belief system for at least the elites in the West and their acolytes can be hardly disputed.

Looked at historically, one of the most important aspects of modern economic theory and practice is that it represents the first and most successful form of systems theory as applied to social systems. This is part of its power; and as will be discussed shortly, is essential to its ethical dimension.

Economics, like the modern social sciences generally, originated in various attempts to do for the social world what Newton had done for the physical world, that is, find a set of simple laws that would explain and underpin a complex set of phenomena. The Scottish and French enlightenment thinkers were haunted by this possibility; and among the first, and among the most controversial, of the attempts at fulfilling this vision, was the provocative work by the British writer (actually born in the Netherlands) Bernard de Mandeville (1714), *The Fable of the Bees*.

In the *Fable*, Mandeville breaks with the moral and spiritual traditions of the world, and argues that private vice should be encouraged, because spending on luxury goods, prostitutes, race horses, etc., generates many public benefits through employment. Here in embryo is the central pillar of neo-conservative thought in our own day. What made Mandeville's work so influential was the linking of local phenomena to global phenomena with opposite characteristics. The social thinker is either to trace the impacts of the local phenomena to their global outcomes from a neutral stance (the view from nowhere), or, even more influentially, realize that the local phenomena can be described quite differently when seen from a higher vantage point. Moreover, the allocation of goods and bads can be dissociated from any notion that the Deity bestows them.

This powerful systems model sat in the armory of the early economists, awaiting further refinement. In the meantime, these economists, including the physiocrats in France (mid-18th century), and the classical economists – Smith, Malthus, and Ricardo (1750s–1830s) began the task of tracing out the transformation of Nature, people, and investments/finance/invention/buildings into land, labor, and capital. With each tracing, the relationship between economic activity and the physical world diminished, and was replaced by the intricate workings of the market.

Perhaps one of the hardest things for a non-economist (actually, for most economists as well) to recognize is that economics does not deal with the physical world. This became particularly true after the first neo-classical revolution in the mid 19th century associated with J S Mill, William Stanley Jevons, and others; and continued into the 20th century (with variations). Instead, it deals with the subjective desires of individuals, as expressed through competing demands signaled by prices, and adjudicated by a market whose other component is supplies, drawn to the market by the price signals, which are re-determined by the interaction of demand and supply. More modern theory speaks of rational allocation of scarce resources, but again, the real world only appears in the tenuous link supplied by an assumption of scarcity.

As a result, in contemporary economic theory and practice, the natural world enters only as it influences prices. If there is no price on koala bears, i.e., no one wants or values them, they do not exist. To deal with this problem (and others) is the domain of the emerging discipline of *environmental economics* (*see* Economics and Global Environmental Change, Volume 5; Environmental Economics, Volume 5). Among the tasks of this discipline are: to find shadow values for environmental goods that do not show up in market prices; to develop surrogate measures for environmental value; subject environmental goods that currently have no legal or proprietary owners to privatization; and generally to internalize within the market what are called externalities.

This environmental economics approach can be compared to the approach of *ecological economics* (*see* Ecological Economics, Volume 5). Ecological economics repudiates the entire superstructure of modern economic thought polemically described above; and rather proposes to return to the kinds of approaches characteristic of the French physiocrats, and others. Specifically, ecological economists focus on a variety of physical aspects of human use of the resources of the earth to sustain life.

This approach considers, among other things, what are the physical requirements to feed human beings, sustain agriculture year by year, harness energy, process mineral and chemical feed stocks for industrial production, and assess the ability of the earth systems to handle the waste products of our activities. There are a number of problems with this alternative approach, of which perhaps the least serious is that there is no consistent set of measuring tools and common language among the variety of competing versions of ecological economists. Economists such as Daly and Cobb (1993) have been working for some years on alternative measures of gross national product and monitoring systems other than price mechanisms.

More serious is the difficulty of internalizing the other economic approach, which, whatever one's views, does currently drive the international economic system. The price mechanism is ingrained into the workings of virtually all decision-making processes, and acts as a fundamental purveyor of information in current society.

Most serious of all are the intangible benefits of the standard economic approach as a moral and ethical system. A lot that could be said about this, but I would like to discuss two issues on this topic briefly.

The first, returning to where this section began, with Mandeville's vision, is that one benefit of the standard economic approach is it allows people to repudiate compassion; or to put it another way, to feel good about being self-interested. Obviously, technical economists (welfare economists and the like) would protest this kind of remark; but I am speaking here about a general cultural influence. Part of the neo-conservative agenda that has been so powerful in recent years is an argument that people who act compassionately towards the poor are acting inefficiently. Indeed, they are, in fact, standing in the way of the improvement in the lot of the poor that would be produced by allowing the market to operate more efficiently. Everything that interferes with the market – social safety nets, public insurance, public health care – is by definition inefficient, and thus drags down the potential for the economy. It is the hard-hearted economic realist who is really the benefactor of the poor.

A related moral aspect of this system is that it is supposedly morally neutral. Since it derives from individual wants, whatever those wants may be, it says nothing about whether some wants are better than others. This classic attack on the amorality of utilitarians is, in fact, a source of pride to economic liberals; though they tend, paradoxically, to bemoan the loss of conservative values like family life that their system is happily destroying.

The second (and related) issue is that not only are the origins of those wants now subjected to gross manipulation by corporate advertising; but at the heart of the system – for a variety of obscure historical and sociological reasons – one can find a powerful model of the human which is being propounded. In this view, contrary to virtually all ethical and spiritual traditions in the world, human beings are fundamentally self-interested, and possessed of infinite desires which can never be fully satisfied; and that rather than try and eliminate these desires, they should be encouraged. Similarly, consumption patterns are now fully seen

as expressions of one s personality. The rise of fashion, the need for status differentiation in an increasingly homogenized world, and the transformation of the citizen into a consumer rather than a producer, have all contributed to the seemingly unlimited growth in consumption in developed countries.

As has been stated by numerous writers, the spread of this in nitely desiring consumer model to the developing world is doubly troubling. Analysts of the so-called ecological footprint the amount of extra resources needed to service developed country growth already argue that we will need three or four new earths to service a world population carrying around in its heads the lifestyles of North America.

MANAGING THE EARTH?

In the meantime, if we look at actual production patterns on the earth, designed to service this population, we can see very important trends in the technical means being deployed in the reordering of the planet for human ends.

Approximately 40% of land-based net primary production (that is, plant-generated material), and over 25% of marine net primary production is now being diverted or rearranged for human use. Much of this is taken by the domestication of livestock, the harvesting of higher animals and sh, and agriculture. This is completely unprecedented.

What is happening around the world is essentially a restructuring of ecosystems in order to maximize production, primarily through creating systems according to at least ve rules.

1. organize for harvesting of natural products at the peak of productivity. The productive peak for many natural ecosystems is at the end of the juvenile phase;
2. concentrate for easier planting/monitoring/harvesting;
3. replace/buffer/enhance ecosystem processes;
4. add value at, and beyond, the farm gate;
5. suppress extra-market externalities.

Here are two examples of some of these rules in operation.

One example is sh farming. Worldwide natural sh stocks are in deep trouble, with something like 34% of sh species threatened with extinction. One solution is intensi ed sh farming in captive tanks. It is calculated that one in four sh that reaches market today comes from a sh farm. The problem is that a sh farm is a monoculture, and all the supporting services have to be brought in from the outside sh farmers are now competing with poultry and pork producers for grain and protein meal supplements, such as soybeans. These farms also produce high levels of waste, they suffer from outbreaks of disease, and forms of chemical pollution.

This is exactly the same situation as in monocultural agriculture. The problem with the average managed eld is that it is trying to turn back into a meadow or a forest. Today s agriculture requires immense inputs of pesticides, herbicides, gasoline for tractors, etc., in order to create an outdoor factory. The most recent types of high-yield corn require that all the microorganisms in the surrounding soil be killed off. This kind of agriculture is becoming more and more expensive, in part because the weeds and the bugs, i.e., the ecological precursors of a return to a meadow, are being chemically and biologically selected for resistance to whatever the latest crop strategy is.

A similar process has been underway for many years in forestry.

Rule one means that crops, trees and sh must be harvested in the juvenile phase and before they level off as adults, at which point it is economically inef cient for them to just be sitting around. This means that there are no older age cohorts left, which also means that the regeneration through decomposition disappears. If you have no old trees, you have no carbon being returned to the soil, no place for insects and other decomposers to nestle in, and so on.

Rule two, which is essential to agriculture and mining, concentration and simpli cation means, in living systems, that there is no diversity, and that makes the system vulnerable to catastrophic attack by virus, bug, plague, weed, or genetic mutation or rapid climate change.

Rule three means that all the processes of energy cycling, nutrient creation, removal of wastes, and so on, have to be imported into the simpli ed ecosystem from outside. In order to do that, energy is required, in addition to resources from somewhere else, which means that some other high-quality ecosystem (or stock of fossil fuels) is being tapped into and degraded. It is based on the assumption that there is always somewhere else left to go to get the supplies needed to feed the arti cial ecosystem.

Rule four, which is well known to farmers, means that the primary production of the ecosystem is virtually worthless it is essentially a host for what will happen next. A potato is worth nothing compared to barbacue potato chips. That is where the money is. A particularly ironic example of this came recently during the collapse of the East Coast Fisheries. One of the largest Canadian sh processors, which was instrumental in destroying the sheries, and has now moved on to the South China Sea, turned its attention to sh species that it had never bothered to sh for before, ground them up, and then rebuilt them as sh ngers in the shapes of star sh and seahorses, and was selling them at great pro t to Colonel Sanders and other fast food outlets in the US.

Rule ve, which is perhaps the most important, is an attempt to eliminate the environment as a part of economic costs of production and marketing. The best example of this the one that is causing global warming is the suppression of geography to enable the smooth running of free trade. Free trade, or if you like, international free markets,

depend upon the ability to ship goods to any place in the world without friction or at very low friction. Distance from one place to another is no longer to be a consideration. The reason this can be done – more or less – is the low price of fossil fuels. Cheap transportation means that California produce can compete, for example, with Ontario produce virtually year round.

The reason why fossil fuels are cheap is that the earth subsidizes carbon dioxide and other emissions. The ecological costs of these fuels are not internalized: if they were, free trade would die tomorrow. As it is, we are awaiting global warming.

POLITICS AND THE WANING OF TRUST

Global change presents us with a number of issues – climate change, the extinction of species, and the disposal of nuclear waste – that require us to think in the very long term, over hundreds and maybe thousands of years. One reason why people have turned to ethicists and spiritual leaders to articulate new environmental ethics, and others to new environmental politics, is a sense that this kind of task is beyond the normal reach of our current ways of thinking, and requires something different. An important recent set of discussions has revolved around the concept of trust', what Niklas Luhmann (1979) referred to as one of the ways in which we try personally or politically to cope with uncertainty over time – through vowing to be trustworthy, trusting others, entrusting ourselves to them, accepting trusteeships, etc.

It is a little known fact that one central element of Western representative democracy grew out of a debate (actually a war) about whom to trust, how to entrust, and for how long, with decision-making power. The British Crown sought (under Charles I in the 1630s) to retain the power of taxation without representation' (to use an anachronistic phrase) by claiming emergency powers to deal with supposed external threats to the nation. Charles wanted to build ships – and get some extra pocket money. The ensuing Ship Money' struggle and the Civil War that followed led the next generation of politicians and philosophers to work on the conditions for declaring emergency powers'. The political theory and practice that evolved further clarified the nature of the entrusting relationship between citizen and government as a whole, first in Britain, and then elsewhere. As outlined by John Locke (among others), the contract between government and citizen became seen to be – in part – based on the entrusting of decision-making power to a representative body for a period of time subject to eventual review by the electorate.

This historical interlude is important because it points up the fact that pivotal to the entrusting of decision-making to representatives was the idea of time: that the government could not always refer back to citizens for every decision and indeed it was important not to do so, when issues were so complex or in need of such speedy resolution that constant referral back through simple referenda, etc., was unlikely to produce a better outcome than focused debates by representatives, who were free to be convinced by their opponents of the wisdom or folly of their position. Obviously, the legitimacy of this entire setup – which is not exactly an accurate description of how things turned out in representative institutions around the world – is now under great stress. Not only are even democratic governments currently more executive and less legislative, for a variety of complex reasons, than the ideal supposes, but citizens are now more educated and unwilling to defer to elected representatives than they may have been; and there has also been an evolution towards at least the rhetoric of more active participation by unelected individuals in the decision-making process. This has been aided and abetted by new communications technologies like the Internet.

Representative democracies have not been able to come up with appropriate ways to respond to this desire for increased participation, and what is in place is somewhat haphazard and flawed; and this has affected the ability of governments and institutions to respond to underlying public anxiety about fundamental environmental questions, and the whole range of longer term concerns in any other way than by bureaucracy. On the one hand, there is an increasing use of single issue referenda, which are subject to manipulation and distortion, but give people a voice' – or at least a gesture. On the other hand, there has arisen over the past while, a whole array of quasi-participatory committees, NGOs, and investigative bodies like the Environmental Assessment Review Panels and Royal Commissions. These usually report to Cabinet or Parliament, and they are supposed to engender trust that the pros and cons of the longer term are being weighed and assessed properly by experts as well as citizens in a deeper way.

These new approaches seem, however, to do little to address some of the more fundamental distrusting going on out there. This is tied to the phenomenon that this section began with referring to: the increasing recognition that decisions being made (or avoided) are extending over larger and larger stretches of time and space, and having effects that are not part of the original mandate' of the political institution making the decision. A classic example of this is the repudiation by outraged citizens of agreements made by town councils, and other local bodies, to site hazardous or radioactive waste facilities – and the casting about for an appropriately legitimate level of government that can make that kind of decision. We didn't elect you to make that kind of decision , is the rallying cry. But democratic countries have not yet found any way of legitimating decisions about where to put high-level nuclear waste for a million years or more, in spite of a multitude of commissions, reports, inquiries, and so on.

Associated with this is an easily awakened mistrust of the elite and professional apparatus of rational management'. Part of the legitimacy of government in our time is in its professed ability to manage any change rationally. The rise of the modern bureaucratic state is based on the premise that utilitarian calculations mixed with expert projection can cope rationally with most of the situations that will arise. So powerful has this rationalization been that on the occasions where symbols of managed rationality have broken down – Three Mile Island, Chernobyl, Vietnam – they have threatened the legitimacy of the entire system of governance. Some philosophers suggest that the special form of rational management associated with the modern world was fatally crippled at Auschwitz. Others, less radically and more hopefully, suggest that people are now less prone to do things just because their government tells them to – like walking unprotected into atom bomb test sites.

Certainly one of the interesting facts of our time is that the citizenry and the environmental radical are often now arrayed on the side of prudential' behavior with regard to proposed future risks; while governments, administrative experts, and corporate elites are essentially risk-prone'. Their trust in their own capacities is undisturbed, in part because they are so locked into short-term forecasting. It is everyone else who finds themselves forced to inject pessimism and uncertainty back into the process; and to mandate the consideration of worst-cases and the very long term.

It is usually said that politicians and the system' are unable to think past the next election, and that this is somehow due to the greediness and short-sightedness of their masters, the electorate. While there is something to this, it is not everything. There are endless examples of the short-sightedness of the expert and the forecaster, whose models accentuate the present and discount the future. The expert can miss the forest for the trees, and the fact that there are no more trees may not show up as a loss on the balance sheet, if the property values can be cashed out elsewhere. Counter to these balance sheets and snazzy models is often something much humbler, more conservative (in the original sense) and simpler: the uneasy sense among the ordinary person that something has gone wrong, and that if we keep going the way we are going, things can only get worse.

Common sense is not all that common, and I do not want to exalt the common man or woman as the paragon of all wisdom. Yet it was the philosopher Karl Popper who made the case that one of the great virtues of democracies was that sometimes the citizenry were the only people who could break the stranglehold of some grand stupidity that was mesmerizing the all-knowing powers-that-be.

In this category – a feeling for the overall wisdom of what is going on – I would put the feel for the longer term. Perhaps it is just living a life, or the fact of having children, or being the latest in a long story line that stretches back in time. Traditional cultures developed methods of thinking ethically over the longer term, and this is one of the reasons they were, in large part, sustainable.

One crucial element of thinking about the longer term, facing the future, is facing towards the past. To develop a sense of responsibility over time, traditional cultures have relied upon ancestor worship and long-standing rituals. Thinking like an ancestor' is a familiar strategy: respect for one's living elders, and one's long-dead ancestors provides one with a compass for what one should do now – and also what one should do to keep faith with those people into the distant future. If we continue to do what has worked well in the past, then the future is secured.

This kind of approach to risks is, of course, threatened when something new and unique comes along like nuclear power or PCBs. It is also threatened across the board by a society that, in cutting itself free from the cycles of the seasons and of ecosystems, no longer values the wisdom that comes from having been through the cycles many times. We value the innovations of the young; the old we discard and stuff away in old people's homes, their wisdom useless to us.

Another attempt to extend ethical or moral sentiments across time is associated with those cultures that believe in reincarnation. In Tibetan Buddhism, for example, people are encouraged to treat animals properly because they were one's mother in a previous lifetime (and there is always the possibility that becoming an animal is one's own fate). All beings are thereby linked across time by familial ties which engender respectful treatment.

A third traditional approach, perhaps more familiar in what derives from a Christian culture, is to see things sub specie aeternitas', that is, under the gaze of eternity or God. One's own actions, or the actions of others, can then be seen as part of a larger pattern or narrative. Related to this is the idea of the moral absolute or imperative.

Moral absolutes are associated particularly with the work of the German philosopher Immanuel Kant, who expanded on a rich tradition going back at least to Plato. Moral absolutes (such as thou shalt not kill) are supposedly free from historical or geographical specificity. This means that they stretch throughout time: it will always be wrong to do this, whatever the change in the situation. This kind of absolute moral stance can also reflect a belief that the consequences of one's acts are not important – that one should do the right thing, whatever happens.

Long-term issues tend to foster absolutist positions, partly because the sense of a problem stretching out for a long time comes to equal forever'.

A moral and ethical consideration which seems to be new to our time is the idea of not doing anything to undermine the sustainability of life on earth – we might say to

fray fatally the fabric of things'. This new consideration derives from our considerably enhanced power to affect earth's biological and physical systems, which we have always previously been able to take for granted. Seedtime and harvest shall not fail was God's pledge to Noah after the flood. Hans Jonas (in his 1984 book, *The Imperative of Responsibility*), referred to this as the ontological imperative'. Essentially, human beings are now subject to a physical imperative which is simultaneously a moral imperative: the basic rule is not to threaten the continuation of life systems on the Earth.

Many people already subscribe to the most drastic version of this imperative, which shows up as a revulsion towards extinction of species. It is a widely shared belief (supported by surveys) that since extinction is forever', endangered species require special treatment. It is not clear how old this sentiment is: that is, previous generations likely lacked the ecological knowledge (as do we still in many cases) to predict the ultimate consequences of the wanton destruction of individual members of species to the point where reproduction became impossible. A widespread assumption was that there were always more Xs where X came from.

So there are perhaps gestures towards some new moral imperatives based on a new awareness of our capacities for destruction; and the broadening of a new moral horizon, based on our anxiety that there should continue to be dawns over the old horizon for as far as we can envision the future.

THREATS TO THE INTIMATE

The concerns over the threats to the fabric of life implied by certain facets of global environmental change have begun to return – as in Rachel Carson's day – not just to the local impacts and expressions of global change, but to what could be called *threats to the intimate*.

An ordinary threat to the intimate is the issue of endocrine disruptors – the possible disruption of the human endocrine system by some combination of the bath of chemicals within which people in modern societies operate. But a more extraordinary threat is posed by the prospect of genetic engineering, including ultimately the engineering of human life.

Because genetic engineering obviously involves getting down to the guts of things, it is obvious that it provokes great fear and concern, some of which may well be technically unjustified. However, the underlying fear and concern is connected to the themes I have been discussing. We are on the verge of having human beings determine what the nature of the human is going to be. This presents us with a kind of moral vertigo, rather like sitting in a barber's chair looking into an infinite set of retreating mirrors.

For environmentalists, the spread of uncontrolled bioengineering is certainly of concern; but it would be foolish to deny that there is also a visceral reaction to the whole enterprise, controlled or uncontrolled. This reaction is part of the often-unnoticed, deeply conservative strain in environmentalism; and it is in part a reaction to the often-unnoticed, deeply radical strain in the modern economic enterprise. The fact that critics of protestors against bioengineering use a variety of economic and utilitarian arguments reinforces the belief that the experiment with the natural world is part and parcel of the growing push to experiment on human beings, who are, after all, themselves part of the natural world. So one is forced back onto some very old and familiar debates: is there more to human beings than their material parts, than their genetic makeup, etc? If there is, what is its basis?

At the end, we return to the image of the earth from space. The French existentialist philosopher, Gabriel Marcel once made a distinction between what he called *problems* and *mysteries*. Problems – from the Greek word *problemata*, to throw in front of – are things that one can stand back from and attempt to solve from the outside. They can be cracked open, like nutshells. Mysteries, on the other hand, are things or questions that cannot be handled in this way: the more you try and solve a mystery, the more it pulls you in, the more it involves you personally in its solution. Murder mysteries are really problem novels – there is a problem to be solved, and the detective moves on to the next one. True mysteries simply expand, deepen, the more you probe into them; and usually bring into question your own deepest beliefs and concerns.

The earth from space looks like a problem – How to manage planet Earth? is a familiar phrase, brought into currency by a special issue of *Scientific American* in 1989 – but it is in fact a mystery, since it encompasses us, and calls into question the deepest wellsprings of our current World Project – the transformation of the ground out of which we came into something more akin to our own wishes and desires.

The Changing Human–Nature Relationships (HNR) in the Context of Global Environmental Change

BERNHARD GLAESER

Social Science Research Center, Berlin, Germany

In his 'Metamorphoses or Transformations', completed in the year 8 AD, the great Roman poet, P Ovidius Naso tells the story of changes in nature, mythology, and human history. In particular, the philosophy lecture in Book 15 gives an amazing account of natural and social change that include such themes as global change (GC), the Gaia hypothesis, environmental destruction, and human and political development. Ovid's depiction demonstrates the broad scope of natural and social change; it is the starting point for this attempt to discuss a variety of perspectives concerning the changing relationship between humans and nature in the context of global environmental change (GEC).

The overall objective of this introductory essay is to convey a broad view of social and cultural aspects of GEC. It represents a Western, social science perspective, and re ects on today's discourses as in uenced or characterized by the turn from the second to the third millennium. It is concluded that the international scienti c community can and should play a vital role in nding solutions to sustain the environmental conditions for the sake of global livelihood, including social justice.

NATURAL VERSUS SOCIAL CHANGE

Relationships between humankind and nature are first of all physical and material: they determine the very substance of and conditions for human survival. But, at the same time, humans interpret and construct relationships between themselves and nature. It is this complex interplay that constitutes and complicates consideration of the social and cultural aspects of GEC. Shifting perceptions relate to physical, economic, social, and cultural changes over time. The changing relationship between humans and nature is an open issue; the cultural and social sciences attempt to interpret it in terms of the following questions: What did the human nature relationship (HNR) look like before and after the start of GEC? What is the specific difference? When did GEC occur and with what consequences for the HNR? We do not really know the answers to these questions for several reasons.

- Natural as well as social systems are determined by perpetual change . When change ceases, the system stops functioning and perishes.
- There is disagreement as to the novelty of GC, because there is some dispute over the meaning of the term globalization . One view is that globalization indicates Western modernity; that it was initiated by Columbus discovering and exploiting the New World, followed, in turn, by the rise of capitalism and the age of technology. This view is based upon the idea that the Renaissance combined wisdom and the power of Mediterranean antiquity with northern European modernity, which really means globalization on a temporal, historical scale. We may note that the dominant view of globalization is entirely Eurocentric.
- Opinions differ as to the values attached to nature and the nature–human relation. These values depend on the degree of an individual's exposure to nature, the needs he or she attaches to nature, the capacity for self-reflection contained in these various concepts and the willingness to abstract from nature. Individuals, ethnic groups and cultural systems construct their own concepts of nature on which they rely and to which they relate. Stakeholders shape the respective HNRs.

These reasons suggest the following point of departure and focus. Since natural and social systems are characterized by perpetual, uninterrupted change, we shall focus on what appears to be its present mode, at the turn of the 21st century, and its corresponding interpretations, concepts and constructs. Humans and nature: which is central, which is peripheral? The age-old question is again raised. It has ethical and political consequences; these are labeled respectively as the *anthropocentric* and, conversely, the *bio-ecocentric* approach. What is the dominant concept of nature? Nature may mean cosmos, the origin of life, an object for philosophical contemplation or artistic production – not to speak of its practical form as a natural resource serving as a vital factor of economic production. Are there different cultural outlooks, such as a typically oriental or typically occidental perspective? Ex oriente lux, enlightenment from the Orient, was the belief or romantic fashion at different ages, including contemporary New Age culture.

What is the importance attached to the relationship-to-nature topic and who are the winners and the losers of GEC? In Europe, during the 1990s, environmental issues lost a lot of appeal to issues of job security and the labor market; whereas in the rural developing world, environmental degradation and loss of soil fertility are often synonymous in that they determine income, livelihood and survival chances – those of rural women more than anybody else (Kiely and Marfleet, 1998; Klingebiel and Randeria, 1998).

Finally, how does the sustainability concept serve in this context and at this point: What is its social dimension and its political outlook? Holistic, interdisciplinary or transdisciplinary approaches have won recognition. Consequences are felt by the research community who have become stakeholders in this field. The mode of knowledge production will change and this implies yet another relationship: that between the natural and the social sciences as well as that between the sciences and the participatory involvement of other (non-scientific) stakeholders affected by GEC. In the political arena, global environmental politics is becoming a strategic issue as conflicts over water have already appeared; environmental security (Brennan, 1999) follows military (Aspen Institute, 1999) and food security (Schulz, 1999). Structural policy is needed to give GC a proper shape (Schellnhuber and Pilardeaux, 1999).

NATURE: IS IT PERIPHERAL TO HUMANS?

As we use ever bigger telescopes to observe the universe, such amplification technology also enables us to literally view the past. We are not too far from witnessing the birth of the universe: Empirical evidence will tell us which hypotheses and theories are to be falsified. Light travels at a velocity of approximately 300 000 $km\,s^{-1}$, which means, for instance, that it takes sunlight a full eight minutes to reach the earth. These simple and well-known physical facts have theoretically interesting implications as scales increase. Imagine that we can see and photograph a galaxy at a distance of one billion light years away! Since the light we've thus observed has been traveling for so long a time, namely one billion years, we are, from a human standpoint, literally looking into the remote past without even knowing whether what we observe still exists.

The Copernican revolution revealed the fact that the Earth was not the center of the universe, or even the center of the solar system. Our earth is simply a minute and by no means unique particle somewhere at the periphery of our galaxy, the Milky Way , and also of the presently known universe. This revelation could not be publicized freely at the time, because it hurt the interests of an important 16th century global player and stakeholder, namely, the Catholic Church. Throughout most of Europe, the Church held a monopoly on the interpretation of not only all metaphysical matters, but also the view of the world and all worldly matters. The Church of Rome represented God the Almighty on Earth, so it claimed, as an institutionalized human trustee. It intended to expand the domain of its monopolistic trust around the globe, along with the worldly powers that used fire and sword to subdue the rest of humanity. So this interpretative and explanatory competence meant power, in a subtle way perhaps. The promulgation of the new heliocentric theory by the Polish astronomer Nicolaus Copernicus (1473–1543) and the rise of science as a whole thus challenged the authority of the Church and its cultural imperialism.

Today, half a millennium later, we witness a second Copernican Revolution (Schellnhuber, 1999) which calls our attention back to planet Earth. The Earth System as a whole is to be analyzed. Understanding it is the basis on which to develop concepts of and for global environmental management. Earth-System analysis (Schellnhuber and Wenzel, 1998) is the holistic and transdisciplinary attempt to model and simulate the *ecosphere*, i.e., the geosphere–biospheric complex, including its climatic history as far back as half a million years ago. This is an endeavor that takes the Gaia hypothesis seriously – the paradigm that interprets the Earth system as a cybernetic whole endowed with a self-regulating capacity (Lovelock, 1979). The basis of this theory is hardcore empirical data that demonstrate that self-regulating biospheric mechanisms have kept the Earth's crust stable and its environment habitable. Biospheric evolution eventually produced humankind.

After four and a half billion years of natural and eventually cultural evolution we have learned two things. First, we are capable of continuously undermining the conditions for our own survival. Global environmental change in the destructive mode can be seen, for instance, in human activities such as oil spills and toxic waste proliferation, perforation of the stratospheric ozone layer (thus exposing us to more UV–B radiation), or nuclear warfare. Second, we have developed – perhaps to a lesser extent – the ethical and managerial tools to protect and safeguard the global environment against forces of destruction like those just mentioned (Parry and Livermore, 1999; Pearce, 1999).

Again, interpretative and explanatory competence has a significant role. Unlike 500 years ago, when enlightenment and the rationality of science freed humankind from religious obedience to strive toward self-determination, it may now be the interpretative dialectics of mythology that reveal the destructive mode of science and technology: Humankind has become simultaneously Shiva and Vishnu, the Hindu gods who represent the concepts for Destruction and Preservation, respectively.

THE MILLENNIAL SHIFT: GNOSTICISM AND THE ENVIRONMENT

Today, at the beginning of the third millennium (AD in our Christianity-centered temporal accounting) environmental management has to cope with GEC. Fears of global destruction and extinction witnessed the earlier transition from the first to the second millennium. According to the doctrines of Gnosticism, salvation could be attained only through the pursuit of spiritual truth and the transcendence of matter. Jesus Christ was considered by Gnostics to be noncorporeal. In keeping with this doctrine was the belief that the beginning of the second millennium would bring about the spiritual age. Gnosticism incorporated an apocalyptic and chiliastic vision of nature's decline and God's ultimate reign over Earth, 1000 years after the birth of Christ. Chiliasm is the doctrine stating that Christ will reign on Earth for 1000 years; ancient gnostic knowledge and belief originated in Mesopotamia, Syria, and Egypt, around the Mediterranean, and were revived by Scotus Eriugena in the 9th century (Voegelin, 1952, 1959).

At present there seems to be a lack of interest in environmental (including GEC) issues, specifically among social scientists. In the following I draw a parallel between the lack of interest in the natural world on the part of many social scientists and the lack of interest in the physical world by Gnostics. My thesis is that some concept-oriented or social-constructivist social scientists are, or behave as if they were, Gnostics. As proof of this, I briefly review some current journals in the field that devote special attention to the recent millennial shift.

Independent of theories that explore such parallelism, the review provides an insight into which topics academics and editors of prominent journals consider of paramount importance during an historically important period. Some historical dimensions and explanations concerning the development of sociology and the motives of its representatives are presented as these relate to the HNR.

Is GEC and/or the changing HNR of interest to social scientists? A few international academic journals focused their last issues in 1999 (or the first issues in 2000) on millennial aspects: the transition from the second to the third millennium, its meaning and relevance for the development of social or interdisciplinary science. Let us look at four of these journals and their topical issue: two interdisciplinary publications and two specialized publications in sociology. I begin with the interdisciplinary publications, *The*

Ecologist (1/2000) and *Universitas* (12/1999), a German-language journal whose readership is mainly among university instructors and students. Both millennium issues concentrate on gnostic themes.

The Ecologist (1/2000) deals with the cosmic covenant re-embedding religion in society, nature and the cosmos . Emphasized is the role that religion can and must play in saving what remains of the natural world , as Edward Goldsmith puts it in his editorial. Knowledge and values that attributed the utmost priority to the preservation of the creation were once propagated by the various religious groupings or cultures. The rediscovery and revival of ecological themes and cosmic theologies appear to be an environmental priority. The theological underpinnings of most religions relate the individual to society, the natural world, and the cosmos. Mainstream science committed the ultimate blasphemy in that Homo scienti cus has dei ed himself ; mainstream religion has lost its way and needs to return to its roots. Noah s ood symbolizes the forces of chaos. Historical storms and oods in Orissa (India) or Vietnam may remind us of this archetype human failure to observe the cosmic covenant, that is, to ful ll our contract to live in harmony with the laws of nature and the cosmic order (Goldsmith, 2000). Religious inspiration and perennial beliefs are to be found among the primal creeds or religions because these derive from the cosmic covenant the universal revelation given to humans (Grif- th, 2000). Tribal stories maintain such wisdom and its ecological message (Wilson, 2000). So did classical mythology and the ecological worldviews of ancient societies such as those of Greek, Chinese, Egyptian, Indian, or Persian antiquity, by using the notion of the path that must be taken to maintain the cosmic order on which human welfare depends (Chaitanya, 2000; Goldsmith, 2000). Related cosmic and ecological insights are quoted for the Islamic and the Judeo Christian traditions, to some extent in u- enced by the ancient civilizations (Barker, 2000; Echlin, 2000; Murray, 2000; Nasr, 2000; Rossi, 2000; Roth, 2000). The cosmos was embedded in the Church until western scienti c thought replaced the term creation with environment , thus separating human from non-human nature. The message of the special issue of *The Ecologist* is that such desecration of the cosmos ought to be reversed in the third millennium.

Universitas (December 1999) entitles its special millennium issue Endzeiten, neue Zeiten? (Final age, new age?) and focuses on topics of transition (Geissler, 1999) between the two millennia. Western industrial societies have eliminated many rites of passage and transition; the symbolism of reworks, for instance, whose original intention was to vanquish evil spirits , has been lost. Instead, the transition from the second to the third millennium has been marked by spectacular events not necessarily of universal importance or interest such as who (in somebody s town) gives birth to the rst millennium baby (Hilgers, 1999). In a similar way, the great issue of the apocalypse has changed. Originally, St. John the Divine pictured the apocalypse in The Book of Revelations as the vision of salvation coming about after a transitory collapse. This transitory collapse is itself frequently referred to as the *apocalypse*. The visionary apocalypse represented the advent of the millennial God s reign on Earth, the New Jerusalem as it was called. In the 20th century, Hitler and Stalin were associated with the advent of the apocalypse. The transitional period during which both leaders were in power was an extremely violent and bloody episode, characterized by massive internment in concentration camps and gulags, and massive human slaughter, in particular genocide. All of this was designed to purify human blood or to convince people to adopt the right doctrine , for the purpose of achieving some perfect millennial Third Reich or ideal post-historic age of communism. Yugoslavia has witnessed a sad revival of apocalyptic nationalism. The cyberspace apocalypse, fortunately somewhat less deadly, has led us into the third millennium. Virtual reality represents the New Jerusalem ; the cybernaut, as the new human , exists independently of bodily needs and achieves immortality as part of the permanent memory of a computer network. St. John s millennial Third Reich becomes the age of knowledge beyond the ages of agriculture and industrialization (Vondung, 1999). The fear of collapse was stirred up by the Y2K problem , the possibility of a global computer network breakdown. This was originally a technology problem that was heavily and massively mythologized perhaps because billions of dollars were at stake (Csef, 1999). Among the many predictions concerning the year 2000, the 1972 Club of Rome report on the limits to growth was misunderstood as a model to predict the real breakdown of the global economy due to resource depletion, environmental degradation, and population explosion (Schmid, 1999). To summarize, Gnosticism plays a vital role in the *Universitas* millennium issue. Global environmental change and changing HNRs are included but do not feature centrally.

Globalization is featured outside the main section of that special journal issue in an interview (Reif, 1999) conducted with Harold James, a Princeton University historian, who speaks of globalization beginning in the 19th century and suggests that while the process may be deplorable for some, it is nevertheless irreversible. James cites earlier historical events and occurrences as evidence for globalization, such as the rst transatlantic cable in 1866, the New York stock exchange crashes of 1906 and 1907 and their immediate repercussions on the European stock markets, or unifying global trends in fashion, including the Japanese adoption of Western dress and fashion, and similar trends in the ne arts since the age of the Renaissance. As one reaction, globalization has also provoked some outcry such as the one referring to it as the

globalization trap (Martin and Schumann, 1996) or critics in the developing world who say, globalization equals imperialism . Earlier (just as they are today) protective tariffs were designed to bar international competition. Welfare and social legislation was designed to strengthen the nation state. Visionary third-ways , such as an attempted balance between the market and planned economy, are viewed by some as roads leading directly into Third World underdevelopment. GEC and the HNR do not appear to be connected with globalization in the sense it is used here.

The sociologist's world-view, similarly, seems in general to be less environment related and nature minded. We shall now turn to two sociology journals and consider their millennium special issues.

The British Journal of Sociology (1/2000) and *Current Sociology* (4/1999) take up the millennial problematique, the latter focusing on the future of sociology and the social sciences , the former on sociology facing the next millennium . This could be an indicator of the importance attached to the issue of GC and the nature–human relationship by eminent mainstream sociologists. The latter journal invited its contributors to consider what the Millennium might indicate about the history of human societies' and especially how sociology' is facing up to the challenges and opportunities posed , and to provide analyses of such transformations (Urry, 2000). Manuel Castells opens the volume by proposing a grounded theory of the network society as the social structure of the information age . The networks are empowered by the new communication technologies and reshape the relations of production, consumption, power, experience and culture. Ecologism is an example of an alternative network in opposition to dominant networks (Castells, 2000). Since the 1960s, globalization (along with complexity analysis and cultural studies) has transformed the context of sociology, according to Immanuel Wallerstein. He proposes a unified or re-unified historical social science as a truly global exercise (Wallerstein, 2000). Goran Therborn documents the shift from a universal to a global sociology in the second century after sociology became a discipline. He forecasts a comparative and competitive focus among the neighboring disciplines – sociology, political science, and economics – rather than along the social-versus-natural-sciences divide (Therborn, 2000). Cross-cultural, empirical comparison of societies in transformation, without worrying too much about theoretical concerns, is advocated (Esping-Anderson, 2000). The conflict between the patchwork quilt of nation-states and the cosmopolitan order of human rights may open the door to the second age of modernity (Beck, 2000). Contributions on urban sociology (Sassen, 2000), cultural diversity and the internet (Featherstone, 2000), and mobile sociology (Urry, 2000) conclude the volume.

Dissenting from the social sociology orientation, a natural tilt can be detected in subsequent contributions. Science and technology studies and the social explanation of natural scientific facts work towards a physical sociology and its epistemology (Latour, 2000). The focus on socioenvironmental theory and the case of genetic modification of food reveal that the social sciences' relationship to nature and environment matters (Adam, 2000). Timescape is conceived as the temporal equivalent of landscape. The timescape analysis of socio-environmental matters brings contextualized temporal complexity to the heart of social theory . Thus the time aspect is central to understanding sustainability and its emphasis on nature's regenerative capacity. Intergenerational equity and cultural equity are at stake – the ownership of reproduction has been transferred to transnational companies. A time-sensitive scholarly enterprise is ••• the task that confronts social theory at the beginning of the new millennium (Adam, 2000).

Current Sociology (Volume 4, (4) October 1999) reports the results of the symposium on The Future of the Social Sciences in the 21st Century which was the concluding session of the 14th World Congress of Sociology in Montreal in August 1998. The whole journal issue dwells on the pros and cons and various aspects of interdisciplinarity, of opening up to and collaborating with neighboring disciplines. Disciplinary boundaries should be negotiated, not simply closed down. To think in space-time and touch geography and history is recommended (Massey, 1999; similarly Allardt, 1999). An active interdisciplinarity is needed, in particular with economics, and also a transdisciplinary or intercultural approach (although the latter terms are not used explicitly, the idea they encompass is implied) to link up with different regions or countries in the age of globalization (Boyer, 1999). Finally, all fragmented perspectives, including those of singular, exclusive disciplinarity, ought to be abandoned in favor of a theoretical unitary reconstruction of the social sciences, if we wish to avoid both the barbarism of economist reductionism and the conservative nihilism of post-modernism (Boron, 1999).

Are the millennial issues representative of social science and interdisciplinary thinking? Do they address the pressing environmental themes substantively and sufficiently? To take up the scope of interdisciplinarity is certainly laudable *per se* and represents present-day avant-garde scientific development. The scientific base, though, appears a little narrow as the natural sciences have been left out, by and large. The HNR in the context of GEC was obviously not considered to be of major concern in the wake of a millennial shift. A few environmentally based and theoretically challenging contributions were competently put forward in the *British Journal of Sociology*. They do not, however, constitute anything close to a social science mainstream movement. To construct a concept of nature and the HNR is hardly even attempted. What are the conclusions as to

the relevance of the HNR and GEC for the social science mainstream? Has there been visible change?

Let us briefly review some specific aspects of the environmental sociology discourse as it began in the 1970s (we set aside the Chicago School of sociology in the 1920s) along with the global environmental movement. We argued earlier (Glaeser, 1996) that environmental sociology became established as a sociological subdiscipline in the US within the short time sequence from 1978–1980. The theoretically ambitious goal at that time was to acknowledge physical and biological factors as independent variables that influence the dependent variables of social structure and social behavior. This was intended to become a new paradigm within the sociological knowledge canon to turn the sociological mainstream towards an HNR concept.

The new disciplinary paradigm was defined through transforming the human exemptionalism paradigm (earlier called the exceptionalist paradigm) into the new ecological paradigm (Dunlap and Catton, 1979). Traditionally, the dominant world-view had been to accept humans as the one unique and superior creature on Earth, capable of quick adaptation to environmental change for cultural rather than genetic reasons. The new ecological paradigm also deviated from a specific sociological tradition established by the early French sociologist Emile Durkheim (1858–1917), who postulated that social facts can only be explained by other social facts. In a most authoritative assessment, Buttel concluded in 1987 that environmental sociology had found recognition as a speciality within sociology. It did not succeed, however, in redirecting mainstream sociology (Buttel, 1987). In our view, Buttel's evaluation was still valid in the 1990s (Glaeser, 1996); it provides the historical background and a broader base for the millennial focus discussed above.

There was one innovation, however, that gradually altered the social science outlook. During the preparation phase of the United Nations Environment Conference on Environment and Development (UNCED) Rio summit in 1992, GEC came up as a new political and scientific paradigm: In 1987, the theme had not yet been included in Buttel's (1987) state-of-the-art review and agenda for environmental sociology. Once again sociology was slow in the uptake. An early exception to this was a contribution by Buttel and Taylor (1992) who advocated in favor of the society-nature relation as a social construct; they argued as well that the GEC topic was a social construct simultaneously serving as a scientific concept and as a way of mobilizing the community of scholars. In short, environmental science and environmental movements are complementary. To date, we might interpret that proposal as an early attempt to integrate environmental stakeholders in a transdisciplinary scientific approach. Even at present, the HNR theme within the GEC context is still not social science mainstream, but it has gained momentum as will be demonstrated below. This is especially the case for the sustainability discourse in the context of the social situation in the early 21st century. The remaining parts of this contribution will examine somewhat more closely the social dimension of sustainability and present some consequences with respect to historical, theoretical, behavioral and political aspects of the HNR within the GEC context.

SUSTAINABILITY: THE SOCIAL DIMENSION

What matters about GEC and sustainable development is the human dimension . But obvious difficulties arise when operationalizing this idea (Rotmans, 1998; Rockwell, 1998). The concept of GC is broader than that of GEC. GC refers to the totality of changes on the planet Earth, including all human intentions and alterations (Rotmans, 1998). It involves both the biophysical and the human system, whereas GEC refers to the human-induced biophysical changes only. To disentangle the natural from the anthropogenic changes within the GEC framework represents a major exercise fraught with difficulty.

The sustainability concept, according to Merle Jacob, is ambiguous; its utility diminishes when one tries to operationalize the concept (Jacob, 1996). The ambiguity, oscillating between an anthropocentric orientation that focuses on the needs of future generations, and an ecocentric view that concentrates on living within the carrying capacity of supporting ecosystems, owes much to the normative character of the sustainability concept, as Rotmans argues, and depends on the cultural perspective of the actors using it. Hence different cultural perspectives would have to be elaborated and translated into different preferences so as to arrive at an operational definition of sustainable development that is linked to the notion of GC (Rotmans, 1998). The categorization of cultural perspectives and biased preferences could be linked to Dunlap's and Catton's (1979) paradigmatic shift and dichotomy between the human exemptionalist (exceptionalist) and the new ecological paradigm.

Sustainability emerged as a new development paradigm out of the concept of ecodevelopment , its predecessor. The term was popularized by the Brundtland Report, Our Common Future , from 1987. The goal was to reconcile environment and development, yet there was a strong bias in favor of environmental sustainability, which, of course, was necessary to counterbalance the strong emphasis on economic growth.

What is *social sustainability*? When we discuss social, or perhaps more appropriately societal, sustainability we can build on a relative consensus by saying that we are searching for the criteria to explain why and how societies are sustained. It would then be possible to make some reasonable predictions about the future. We use data from six to eight thousand years of human civilization composed of, say, 200–300 generations of people. Biologically speaking, this

is minute even though we tend to think of it as a relatively long period in historical, political and sociological terms.

What are the factors that maintain or help maintain a social entity for a longer period of time, such as a social group or society at large? Putting the question like this, hints at a quick and simple answer. On closer investigation, however, we see that it might involve the totality of social science theory including those parts that are yet to be written. With all of these constraints in mind, Serbser (2000) in a contribution to *Gaia* (*see* Gaia Hypothesis, Volume 5) – a Swiss–German, multidisciplinary journal covering ecological perspectives in science, the humanities, and economics – suggested the following procedure. Let us identify those or some of those necessary conditions without which social (societal) survival would not be feasible. We talk about formal requirements in a pragmatic sense: they should be independent of each other, yet in combination constitute the societal context in a total bio-cultural sense. Six preconditions (three cultural and three ecological) for a sustainable human society are suggested. The cultural order contains social action, constitution of social groupings, and their transformation in the sense of social change. These conditions for societal sustainability are contained in and derived from established contributions to sociological theory. The ecological order includes social space, social metabolism and dominance.

Social action is intentional and linked to symbolic systems such as our language, which is sufficiently imprecise to enable us to deal with complex issues. Social groups or social units as subsystems are constituted by the notion of self-identity and, complementarily, by a sharp outline defining other, competing social units. These groups undergo a constant process of reorganization, that is, transformation or social change. Social groups need a spatial environment as a constituting frame. Social space defines the situation of social action; it determines symbols and language. Social metabolism refers to the activities and interactions of social groups: they produce, they consume, and they reproduce themselves, under a regulatory framework of legal and ethical principles. Dominance, finally, refers to social control, the power structure and governance (including the system of checks and balances).

All six features – social action, social groupings, social change, social space, social metabolism, dominance – according to Serbser (2000), work in combination and, as an interacting set, they determine the survivability and sustainability of a society. But (as Serbser notes with regret) these features and their interaction have hardly been taken into account in the social sustainability discourse.

As these ideas are very recent, they are necessarily still somewhat vague. The yardstick to measure the degree to which they are analytically concrete and applicable could be as follows: First, they could serve as a tool to facilitate the determination, perhaps on a quantitative scale, of whether or not any given social (or societal) situation is sustainable. Second, in a more dynamic sense, they could produce recommendations for the implementation of measures as an incremental approach to societal sustainability.

The examples of integrated and sustainable coastal management or the deep sea commons, to take extreme and topical examples for regulated social processes, show that inequalities or simply competing interests need to be negotiated in a process of mutual control and bargaining. Even if some disagreement remains, consensus must be reached on the degree of disagreement accepted. If this does not happen, social exclusion will occur, either voluntarily or as a result of external force. The state or process of social exclusion is certainly not a sustainable one because there will always be group members, be it individuals or states, that will aim to reverse a dissatisfactory situation. It may thus be concluded that consensus building by negotiation indicates a state or process of social sustainability. We may term the absence of such indicators negative social sustainability .

Global inequality is a topic that was discussed extensively in the 1970s – on an international scale, as early as 1972, during the United Nations Conference on the Human Environment (UNCHE I) in Stockholm (Glaeser, 1997). The theme took on a new dimension during the GEC debate. More explicitly than ever before are North–South relations and inequalities linked to environmental problems that have been intimately connected with livelihood concerns. Following the two oil crises of 1973 and 1979, and the lost decade of the 1980s which was characterised by huge public debt and structural adjustments in the South, GEC is no longer defined within a social or cultural context (Redclift and Sage, 1998).

Environmental problems are viewed differently in the South than they are in the North. Poverty ecology gives priority to livelihood concerns (Agarwal and Narain, 1991); the focus is on the impacts of trade liberalization, the repayment of international debts, and structural adjustment. These aspects of globalization differ markedly from the lifestyle concerns characteristic of Northern wealth ecology . Here the environmental problems associated with GEC are climate change, acid rain, ozone depletion, loss of biodiversity and the collapse of fisheries in various parts of the world. Two decades after the United Nations General Assembly had agreed in 1980 on a drinking water decade (Glaeser and Phillips-Howard, 1983), the absence of clean drinking water is still considered to be the major environmental problem for millions in the South, causing disease and epidemics as recently illustrated in Mozambique in 2000. The International Monetary Fund (IMF) policy and other adjustment policies may be responsible for environmental degradation when resource needs increase or

additional pressures are exerted, for instance, on marginal soils or common goods. Two striking examples of this are forest depletion due to firewood extraction and fish stock depletion in coastal waters due to over-fishing and eutrophication.

Equity conflicts are social sustainability conflicts. The South cannot sustain itself in social terms if social inequalities exist. To reduce inequalities means to come closer to intragenerational equity which, on the other hand, could contradict intergenerational equity, that is, the care for future generations. Both equity issues could contradict the policy of environmental efficiency using energy tax incentives or tradable pollution permits. The latter issue, equity versus environmental efficiency, is based on the value we as a global society attach to nature, concretely to the service functions of the global ecosystem, such as the environmental cleanup function – nature's own regenerative capacity. Global commons, such as the oceans, are global sinks; they absorb, in particular, many carbon-based pollutants. Forests, too, act as global sinks in the sense of pollutant absorbers but, unlike the oceans, they are nationally owned. Social justice in the sense of intragenerational equity, for instance, in the case of forests, would thus call for compensation to be paid to the owners of common goods by the polluters. According to Redclift and Sage (1998), a global contract would mean that Southern development concerns would have to be met before Northern global environmental issues are contended with. So we have come full circle back to where we started 1972 in Stockholm! Environment versus development.

From the developing world point of view, poverty reduction, redistribution of wealth and socioeconomic equality or at least equity may be the main issues of social sustainability – environmental sustainability being its prerequisite. Some term it participation , consensus building through negotiation and social competition , or the absence of social exclusion . The overall theme is social justice. In a useful synopsis, Goodland (1995) produced a table in which social, economic, and environmental sustainability are juxtaposed. Following a widely accepted definition, sustainability means maintenance of capital. Capital embraces a social, a human and a natural form. Social (or moral) capital is constituted, among other things, by tolerance, compassion, patience, cultural identity, community cohesion, honesty standards, laws/institutions, and discipline, and requires maintenance in terms of shared values, equal rights, community participation, and religious and cultural interaction. The creation of social capital is needed to achieve social sustainability. Conversely, there can be no social sustainability without environmental stability – the latter providing the basic conditions for the former.

Environmental sustainability (as a pre-requisite for social stability) means that natural capital must be maintained. Human welfare is to be improved by protecting raw material sources and by ensuring proper sinks for human wastes. Renewables are to be kept within regeneration rates; the depletion rate for non-renewables must be kept within the renewable substitution rate. The amount of wastes produced should not exceed the assimilative natural-environmental capacity. Scale is thus added to efficiency and allocation as a third economic criterion. It constrains the throughput of energy and material through the economic subsystem and thus controls the use of natural capital from environmental sources to sinks.

Economic sustainability means holding the scale of the economic subsystem within the biophysical limits and includes production and consumption. Economic sustainability devolves on consuming interest, rather than capital (Goodland, 1995). As economists value goods and services in monetary terms, major problems arise when natural capital is to be valued. This is especially true for resources of common access such as the oceans or air. The problem becomes all the more complicated, once we realize that more than just economic values are attached to natural goods and services. Our understanding of individuals' values is limited; to understand and evaluate choices is a cross-disciplinary exercise. Ideally, economic values are represented by market transactions. If there is no market, as in the case of common access resources, transactions may be replaced by consumers' willingness to spend time or money to gain access, or by their willingness to reveal a preference for a site or a style of recreation (Lockwood, 1999). The willingness-to-pay approach to elicit environmental values may be complemented by participatory social deliberation as a means to inform the environmental decision-makers (Brouwer *et al.*, 1999).

There are obvious limits to the economic valuation of nature and the environment. Economics can certainly not cope with what philosophers term *intrinsic values* of ecosystems, non-human species or the inanimate nature. Whether intrinsic values are justified and necessary for an environmental ethic is still a matter of dispute. The top value in a value hierarchy may be assigned to human survival or human quality of life on the one side, or to landscapes and the natural world on the other. These values will eventually be incorporated into decision processes and depend on (often conflicting) positions held and adopted by stakeholders (Lockwood, 1999). Values and norms must be activated by cognitions specific to the environmental context, for instance, by adverse consequences anticipated for humans (anthropocentric value orientation) or for natural ecosystems (biocentric value orientation). Socio-psychological models are used to measure environmental values and attitudes, and to research whether these have been processed and transformed into corresponding behavior (Dunlap and Van Liere, 1978; Stern *et al.*, 1993, 1995, among others). Held values reflect

social settings and norms and interact with policy issues. To incorporate environmental values and behavior into political decision-making would certainly enhance social sustainability.

It appears that there has been a shift in the logical hierarchy of sustainability whereby the need for social sustainability is a motivating factor to pursue environmental sustainability, which, in turn, depends upon economic sustainability. In this sense, the approach followed appears to be anthropocentric, notwithstanding the fact that the notion of sustainability is inspired by the care for nature and the preservation of the environment, which may be termed enlightened anthropocentrism (Summerer, 1989). Environmental care can be integrated into authentic human development. Authors who agree with this somewhat normative statement will still disagree as to what is included in human development. If it is a rather qualitative concept in the sense of human well-being, measured in terms of health, knowledge, social order or community, it may not correlate closely with the quantitative concept of economic growth and material affluence (Dower, 2000). The question of values shows up again in the problem of alignment or non-alignment of social and natural change, in the Western world-view and enlightenment imperative to control and use nature, and in the dilemma between development and environment.

It is fairly obvious that social sustainability and negative social sustainability to a large extent depend on the theory (or theories) involved. Sustainability and its converse are theoretically constructed but this does not mean that they are untrue or unreal: The notion of social construction simply implies that social action relies on social concepts, and that social concepts depend on perspectives, some of which are scientific. Social constructs determine not only the notion of social sustainability, they also determine the notion of environmental sustainability and, as a consequence, the relationship between humans and their social and natural environment – between societies and nature. These relationships change as the underlying concepts change. The most recent of such transformations occurred in the context of what is most commonly termed, accepted, and constructed as GEC. The natural and the social sciences frame their variegated perspectives to deal with methodologically proper aspects of the HNR. Again, these perspectives are constructed in terms of scientific convention, and from the historical and methodological standpoint represented by a given discipline. Dissidents in different disciplines agreed on a dissenting perspective: that is, a unifying approach. Their scope has been integrative as opposed to analytical – compartmentalized. The holistic approach to dealing with HNRs of various kinds and in a multitude of facets has been called human ecology . *Human ecology*, enriching the synthetic and systems oriented ecological outlook with the social and cultural human actor approach, eventually became a new academic eld and subject of its own.

CONCLUSION: GLOBALONEY OR WHAT?

What conclusions can we draw with respect to HNR and their changes within the GEC context and at the historic opening of the third millennium? We may sort and distinguish between aspects related to history, theory, ethics and behavior, and policy.

History

The public in most countries seems to be poorly informed about global risk issues. This is the outcome of an international survey of public awareness and concern about environmental problems conducted in 1992 by the Gallup International Institute in 24 nations, diverse in terms of their geography, economics and social settings. Yet, even if laypersons have a limited understanding of global warming in a more technical sense, the issue s appearance as a visible social problem has surely heightened the public s general sense that humans are having a detrimental impact on the environment (Dunlap, 1998). These concerns extend from the local to the global environment and include the various aspects of the environmental problematique. Ecological awareness has evolved over decades, beginning in the 1960s, and has developed into an ecological worldview. Public attention may oscillate in accord with uctuating media attention, but it is unlikely to disappear altogether. Environmentally oriented social movements and organizations have mushroomed in the North as well as in the South. To what extent public awareness translates into behavioral changes is a matter of dispute and ongoing research.

The ndings on varying degrees of public awareness, on a basically high level, are supported by a media survey covering the American mass media in the ten-year period from 1987 to 1996 (Mazur, 1998). Until the late 1980s, environmental attention had focused either on biospheric issues exclusively, such as the destruction of rainforest or species extinction, or atmospheric hazards exclusively, mainly global warming, acid rain, and ozone depletion. Theses issues began to cluster during the 1987 1990 period, showing up as global problems. This was also a period of rising media coverage resulting in widespread public attention. Some of these hazards were connected; for instance, the greenhouse effect, the ozone hole, and the extinction of dinosaurs were interrelated in the public consciousness. A drop in the coverage of GEC can be observed for the period from 1992 to 1996, following the Rio summit. There are several explanations for this decline, none of which seems to be wholly satisfactory (Mazur, 1998). One plausible explanation, however, is that new

story lines such as the downfall of the Soviet Union and the breakup of satellite countries in the early 1990s, or the Gulf War in 1991 had greater appeal for journalists and news agencies in an evolving age of news as entertainment: infotainment .

Theory

GC issues and the HNR are polarized between epistemological idealism and epistemological realism. The distinction between the two positions appears clearer than before despite the fact that there has been a certain tendency to tackle conventional environmental problems subjectively in the social sciences and objectively in the natural sciences: environmental awareness and reflexivity versus hard facts and measured observation in environmental reality . Philosophers today may recall a comparable situation in the late 18th and the early 19th century when the German philosopher, Immanuel Kant, resolved a similar academic conflict.

Contemporary social science investigations have either evolved along the path of social constructionism (or constructivism), representing neo-idealism, or they have followed an orientation that pre-supposes a material world independent of percipient human actors (Rosa and Dietz, 1998) – neo-realism.

The neo-realism guides the social and scientific analysis of environmental changes as well as the political economy interactions between environment and society. A famous example is the still influential IPAT model which was proposed in the early 1970s and assumed that environmental impact I is a function of population size P, affluence *per capita* A, and technological development T (*see* **DPSIR (Driving Forces Pressures State Impacts Responses)**, Volume 4). The systems approach in world modeling simulates similar relationships on the basis that there are crucial driving forces that regulate the system and that are probably influenced by policy and politics. Social scientists have often criticized such concepts for being too simplistic. The approach, they argue, is too mechanistic and does not reflect human agency to the extent that it is actually present, that is, the complexity and reflexivity (reflexiveness) of social action and political response (Glaeser, 1995; Rosa and Dietz, 1998).

The neo-idealist orientation towards problems and research on environmental change issues highlights two aspects:

1. the uncertainties in the body of knowledge and the scientific knowledge claims, and
2. the attempt to provide explanations for scientific and public recognition of the environmental change problem as influenced and shaped by historical, social and political forces (Rosa and Dietz, 1998).

In this approach, the emergence of scientific concern and the rise of public awareness are scrutinized; these issues eventually become more important than the environmental problem under dispute. Environmental threats to the global ecosystem or human health are perceived only to the extent that they attract media attention and are publicized accordingly. To a great extent, the social constructivist approach is reflexive, and it is applied as a science of science – meta-theory. Constructivist methodology is useful in detecting critical shortcomings in realist models, which may be based on or entail false (or at least uncertain) assumptions. Social constructionism, on the other hand, has been criticized for neglecting real world problems and concerns in that human–nature relations and environmental change issues are constructed or conceptualized, that is, produced or created rather than extracted or mapped .

It seems wise, then, to re-adopt the Kantian position in the sense that the strongholds of epistemological idealism and realism are to be combined. The critical potential of social constructionism should be retained without forgetting that the survival or livelihood problems facing humankind do not disappear when we turn our attention away from them. We may cautiously suggest that the issue of GEC has largely been adopted by natural scientists, who view themselves as realists. The underlying models and assumptions ought to be scrutinized by reflecting which construction represents which stakeholders' interests. The issue of HNR, on the other hand, has been taken up through idealist social science and theory of science. What is at stake here are HNR changes over time, space, and culture; the social construction of GEC themes is among the relationships under consideration. Recent examples of this include the identification of driving socio-political forces behind GEC, closely related to factors of modernity (Spaargaren and Mol, 1992; Mol and Spaargaren, 1993; Wilenius, 1999); an heuristic reading of classical sociology texts to provide theoretical insights into GEC studies (Prades, 1999), or the sacralization of nature and cosmocentric mythology (Giner and Tabara, 1999).

Ethics and Behavior

We take a closer look at the mythology issue since it takes up behavioral aspects and the ethical complex with respect to ecological rationality. Religious responses to GEC may inspire modifications in how we treat the world environment, this in turn having repercussions for how we conceive human actions and what we deem to be a rational social order. These conceptions have shaped – for certain ecology-minded groups in society, at least – the present cultural situation which interprets GEC as risky.

It is argued that eco-religion is a necessary condition to implant ecologically rational behavior. Environmental anxiety coincides with the chiliastic movement (see the section on the millennial shift: gnosticism and the environment) which views (eco)religious disobedience as cause for apocalypse. GC and growing scarcity are seen as a consequence of our environmental misconduct. Religious responses shift from monotheism to pantheism, whereby nature as God (*deus sive natura*) becomes the object of worship. Examples like Lovelock's Gaia hypothesis or the deep ecology movement illustrate well how this potential can grow into a firm religious belief. Global ecological rationality will emerge as a new form of rationality and induce new cultural contexts of action affecting personal individual behavior and action to mitigate environmental destruction. Whereas eco-religion will eventually die, its behavioral aspects may still remain ••• with future generations. The ecological ethic will thus survive the spirit of the corresponding religious beliefs that inspired it ••• (Giner and Tabara, 1999).

While the notion of ecological rationality considers the intricate relationship between religion and science, the mechanisms and processes for social change as a means to achieve global ecological rationality are not revealed. Still, it should be noted in our context of HNR that the metaphysical and ethical components of transformation are linked to social behavior and policy formation as they relate to GEC (Giner and Tabara, 1999), and as they are finally incorporated into everyday culture, manners and lifestyles of the world population, forgetting their eco-religious roots.

Policy

Environmental policy and management represent the human action approach to GEC in the HNR. Globalization includes global environmental policy and management. Global environmental problems cannot be solved at the national level but the national level will still retain its importance and role in the development of environmental policy. The *subsidiarity principle* is pursued by the European Union. It means that a higher policy level replaces a lower policy level only if the lower level cannot appropriately take care of the problems under consideration. The *subsidiarity principle* is expected to be adopted on a global scale: Local environmental problems should be tackled locally; global problems should be dealt with globally. The pre-requisite that there be competent global scale actors to manage this, has thus far not been fulfilled. There is no World Environment Organization that has the power and the standing of the World Health Organization or the World Trade Organization. The global environment is regulated by Multilateral Environmental Agreements, such as the 1997 Kyoto Protocol, which regulates the reduction of greenhouse gases. The agreement acknowledges global commons to which open access is denied. To date there are more than 170 multilateral agreements to regulate environmental protection on a global scale. National participation is voluntary; not all countries sign or participate in such agreements. Whether an agreement is supported or opposed depends very much on the international epistemic communities that represent expert networks and act across national boundaries (Petschow and Droge, 1999; Swanson and Johnston, 1999).

The international research community on the human dimensions of GC includes natural and social science scholars with common interests, working in universities, research institutions and government laboratories. They communicate with each other at conferences or workshops, through scientific journals, and via the Internet. Major changes in academic development, as induced by global environmental research, include the growing volume of inter- and transdisciplinary research to address human and environmental problems, the commitment to public policy and management, and the rapid diffusion of information, via the electronic media, among the research community and other stakeholders. This new structuring and production of knowledge is sometimes addressed and discussed as the electronic invisible college (Brunn and O'Lear, 1999). The members of the GC community have research interests in various overlapping areas within the human–environment interface: human ecology. They include cross-disciplinary clusters, working on specific topics such as environmental and climate change, land use and resource management, integrative coastal zone management and eco-tourism, sustainable agriculture, environmental protection and food security. The electronic invisible college promotes virtual conferences on specialized topics of GC among leaders, students, and practitioners.

Scientific expertise provides important inputs into environmental policy, planning, and the decision-making process, from global level to local level. A major difficulty, apart from the implementation deficits, which have been widely discussed by political scientists, may be termed here (adopting macro economics terminology) the magic triangle of sustainability . Social (societal), environmental and economic sustainability represent conflicting goals that must be optimized. Optimization means not only a participatory bargaining process between the stakeholders involved; it also requires scientific information, hard or at least fuzzy data with respect to changes in ecological carrying or absorbing capacity for a given region, and resulting social and economic impacts. Sustainability is very often not accountable when it comes to concrete cases. We live in a state of uncertainty regarding scientific data. The ethical and political consequence will then be to act cautiously, in a value-conservative mode: If the precise limits to sustainability are unknown, it is imperative that we not bar the path to increasing or at least maintaining sustainability. Just such a precautionary principle has, to some extent,

been adopted in environmental legislation (*see* Precautionary Principle, Volume 4). Its implementation depends on the HNR that we as the 21st century GEC society wish to realize. Reviewing the politico-environmental agendas since Stockholm 1972, we may state cautiously that ecological modernization , which applies high-tech efficiency and ecological taxes within a growing market, has won acceptance in many countries; whereas ecological structural change , which builds on the social reorganization of society to achieve consumerist modesty and lifestyle self-limitation, is far from becoming a political option.

In summarizing and concluding let me raise a final question: Is all talk of globalization just a lot of globaloney as a number of journalists and critics seem to believe or are there substantive issues that must and can only be dealt with on a worldwide scale – globally; and, if so, what does dealing with them globally really mean (for Occident and Orient, North and South, women and men, rich and poor)? The HNR has been a major theme in natural philosophy for centuries, if not millennia. The aspect of change was added more recently with respect to concepts of nature. The global environment was hardly a human concern before the 1970s – a decade that has witnessed the limits-to-growth discourse, the first UN Conference on the Human Environment, and two oil crises reminding the global society of the simple fact that global natural resources are finite. The *avant-garde* of the social sciences dealt with all of the above issues; by interpreting them as social constructs, to reveal some different perceptions. The scientific community realized that the search for GEC solutions needs inter- and transdisciplinary (including non-scientific stakeholder) synthesis and policy related cooperation (among others: Brewer, 1986; Ravetz, 1986; Committee On Research Opportunities and Priorities For EPA, 1997).

GC is reflected in regional and local development. Development and change in different parts of the world or in different segments of society create winners and losers . Perceptions are usually considered to be a function of culture and development. The inverse tendency is also true: Perceptions such as humans are the masters of the universe (*dominium terrae*) or exploitation of nature enables us to upheave the social order (*dominium hominis*) induce or determine new developments. Globaloney ? This is pretty serious business. Let us work together to turn globaloney into meaningful efforts to provide every citizen of the globe with prosperity, security, and a healthy environment in which to thrive. This is what is intended by globally sustainable politics, policies, and livelihoods.

ACKNOWLEDGMENTS

I wish to thank Wolfgang van den Daele, Rainer Dobert, Ted Munn, and Peter Timmerman for their helpful comments and constructive criticisms of the manuscript in its earlier stages.

I am also grateful to Mary Kelley-Bibra and Emma Aulanko for technical assistance and other invaluable help in the final preparation of this article.

Economics and Global Environmental Change

EBAN GOODSTEIN

Lewis and Clark College, Portland, OR, USA

Confronted with any environmental problem (whether toxic emissions from a local incinerator, or the vast conundrum presented by global warming) the question " how much is too much?" necessarily forms the starting point for an economic analysis. Since pollution and resource degradation are a by-product of material production, and human welfare depends upon both material production and a livable environment, what is the right trade-off? Of course, such a question is a normative one; as such it has no objectively right or wrong answer. Although economists generally agree both on a common ethical framework, and a particular de nition of sustainability as a desirable social goal, there is signi cant disagreement about how much pollution and resource degradation society should tolerate if we are to achieve a sustainable economy. Some support the use of bene t- cost (BC) analysis to guide resource development and pollution decisions; others prefer a stricter precautionary principle.

As economists move to more positive analytical ground, however, broader agreement emerges, though on some points signi cant debate remains. First, why do laissez faire market economies generate unsustainable outcomes? Certainly because of negative externalities. These are dif cult to internalize through private negotiation owing both to the predominance in the economy of open access common property resources, and the diffuse nature of environmental harm. An additional argument is that markets encourage investments with rapid paybacks, at the expense of longer-term investments.

Second, are there ways to reduce the costs of environmental regulation? Certainly by shifting away from the current prescriptive forms of regulation, to more exible, incentive-based (IB) approaches. A second approach supported by many environmental economists is to promote direct investment in clean technology.

Finally, how can we promote environmental quality in poor countries? First, raising incomes for the poor majority is a critical step; in the face of desperate poverty, the environment will become rapidly degraded. Second, progress can be made in reducing population growth by recognizing the economic motives underlying fertility decisions. Third, the complex links between rich country consumption, the movement towards free trade and investment, and global environmental quality are important factors, if still poorly understood. Fourth, effective global environmental agreements are hard (but not impossible) to achieve because they are public goods, subject to free riding.

How much pollution is too much? How can we do better? And how can we resolve pressing global environmental issues? Economic approaches to answering these questions share the goal of shedding light on the trade-offs implicit in different environmental policy choices.

THE ETHICAL FRAMEWORK OF ECONOMICS: UTILITARIANISM

Economists are in the contentious business of recommending what they perceive to be the mix of government policies and private market institutions needed to maximize, in Adam Smith's words, The Wealth of Nations . Wealth in the economist's context should be interpreted broadly to mean all those things that bring people a high quality of life. Societies are poor, not wealthy, if they have polluted air and water; if they lack wilderness areas for recreation and solitude; and if they are unable to satisfy a moral desire to protect other species from extinction.

It is important to emphasize that economic analysts are concerned with human welfare or happiness. To an economist, saving the blue whale from extinction is valuable only insofar as doing so yields happiness (or prevents tragedy) for present or future generations of people. The existence of the whale independent of people is of no importance. This human-centered (or anthropocentric) moral foundation underlying economic analysis, which has

as its goal broad human happiness or utility, is rooted in the 19th century ethical system known as *Utilitarianism*.

Some environmentalists are hostile to utilitarian arguments for protecting the environment. Indeed, an economic perspective on nature is often viewed as the primary problem, rather than part of the solution. The philosopher Mark Sagoff (1995, 618) puts it this way:

> ••• the destruction of biodiversity is the crime for which future generations are the least likely to forgive us. The crime would be as great or even greater if a computer could design or store all the genetic data we might ever use or need from the destroyed species. The reasons to protect nature are moral, religious and cultural far more often than they are economic.

The focus on anthropocentric, utilitarian arguments by economists is not meant to discount the importance of other ethical views. Indeed, over the long run, non-utilitarian moral considerations will largely determine the condition of the planet which we pass on to our children and theirs. But economic analysis is firmly wedded to this utilitarian ethical framework; moreover, arguments about human welfare invariably crop up in debates over environmental protection, often playing dominant roles.

Within this utilitarian worldview, sustainability takes on a particular meaning. Sustainable outcomes require that we reduce pollution (or stop depleting resources) if doing so, on balance, prevents the decline of living standards below their current level for the typical (median) member of any future generation (Pezzey, 1992).

MARKET SYSTEMS AND SUSTAINABILITY: EXTERNALITIES

Economists largely agree that pure free market systems are unlikely to generate sustainable outcomes (Goodstein, 1999a, Chapter 3). *Laissez faire* systems fail because of the existence of negative externalities: costs generated in the production or consumption of a good which are not borne by the producer or consumer of the good. For example, when I buy a liter of gasoline and burn it in my jet ski, I impose a variety of costs on society as a whole, ranging from the emission of local air and water pollutants, to global warming. Many of these costs are not reflected in the price of gasoline. They are thus external to the buyer and seller.

If all resources in an economy were privately owned, and environmental damages could be proved easily, then externalities would be internalized through private negotiation or litigation. For example, if Bill Gates owned the Mississippi River, and my jet ski was polluting it via emissions of soluble hydrocarbons, then Bill could sue me and force me to internalize the external costs imposed on his river. However, many important resources are not privately owned: the air, rivers and streams, oceans, most forests, deserts and other natural habitats. Moreover, environmental damages are often spread among many parties, and difficult to prove in specific cases, creating high transactions costs for private resolution of the externality problem. Given these two features (the widespread presence of common property resources, and the high transactions costs associated with court claims for damages) economists agree that free market systems will generate excessively high levels of pollution and resource degradation.

The conventional solution to this problem is to force companies and consumers to internalize externalities through government regulation. Regulation can be either prescriptive (command-and-control, CAC), in which firms are required to install particular types of clean up technologies, or it can be incentive based (IB). The latter approach includes both pollution taxes, and marketable permit systems. These IB methods internalize externalities by forcing firms to pay for pollution, but leave the specific method of pollution reduction up to the companies themselves. (These systems are discussed more fully below).

If government forces firms to pay for pollution through regulation, how much should firms pay? The conventional view is that businesses should pay an amount per unit of pollution equal to the damage done by the last unit of pollution emitted (the *marginal unit of pollution*). Thus, if the last ton of sulfur dioxide coming out of a power plant stack leads to economic damages of $200, than the plant should pay $200 for every ton that it emits. In competitive markets, setting pollution prices equal to marginal economic damage in this way balances the costs of pollution control (higher prices for products like electricity) against the benefits (less damage from pollution like acid rain), leading to maximum total monetary benefits to society.

Economists have developed a variety of techniques to determine monetary values for pollution damages (Goodstein, 1999a, Chapter 8). These range from the mundane (fewer sick days for workers) to the highly controversial (placing a dollar value on stroke deaths prevented, reduction in child IQ avoided, or biodiversity preserved). How can these latter types of valuations be done?

As one example, the value of a life saved in benefit–cost (BC) studies typically ranges from $2–10 million. These numbers comes from studies that examine the wage premium for risky employment. Put overly simply, economists have found that workers like police officers receive a wage premium of around $500 for accepting a 1 in 10 000 increase in the risk of premature death on the job. 10 000 police officers thus exchange one of their lives for about $5 million.

One can quarrel with this line of reasoning on many grounds. And clearly, if considerations of this type dominate, then uncertainty in dollar valuations of the benefits of environmental protection can loom large. Nevertheless, economists have developed a number of tools for monetizing important components of quality of life traditionally left out of measures like gross domestic product (GDP).

This allows society to put a monetary value on pollution prevention: for example, global warming damage estimates from carbon dioxide emissions from coal fired power plants range from around half a penny per kWh to three cents per kWh (Krupnick and Burtraw, 1996). And while numbers in this range may ultimately turn out to be wrong, defenders of this kind of estimation of the dollar benefits of environmental protection respond that even the wrong dollar value is better than the default price of zero.

MARKET SYSTEMS AND SUSTAINABILITY: SHORT TIME HORIZONS

While the problem of externalities can, in theory, be dealt with via regulation, free market economies have another feature which may lead to unsustainable outcomes. In modern market systems, firms expect profit rates of return on the order of 15 to 20% in order to induce them to either conserve resources or to invest in new technology. With such high discount rates, projects with payoffs occurring much more than five years in the future seldom look profitable. Thus, from a business perspective, it seldom makes sense to preserve rainforests on the grounds that in 50 years the biodiversity it contains will be highly valued; neither are energy companies much interested in solar power as long as cheap oil and coal have at least five year lifetimes.

It is easy to show that these short time horizons create a situation in which future generations are not as well off as we could possibly make them. If we invested more today in conservation of certain resources or in basic research and development (R&D), then we could with a high probability raise the welfare of our descendants. This is the general rationale for government support of science and technology. However, it is not clear whether our short-term bias is unsustainable, that is, whether it actually reduces the welfare of future generations below the level that we enjoy today. Even with their short-term biases, market systems are incredibly dynamic in terms of the development of new technologies. It may be that the five-year time horizon (coupled with government support for longer-term research) can still insure that the well-being of future generations will not decline. This depends in turn on the degree to which new technologies can substitute for depleted or degraded natural resources and ecosystem services (Goodstein, 1999a, Chapters 6 and 7).

SUSTAINABILITY: THE NEOCLASSICAL VIEW

The sustainability debate hinges on this issue of human-created substitutes for natural capital: inputs (raw materials) and waste sinks serving the economic system. On this point, two camps have developed: *neoclassical* and *ecological*. The neoclassical tradition in economics is based on a vision of broad substitutability of inputs and outputs: labor can substitute for capital in production; oranges can substitute for apples in consumption. Neoclassical economists acknowledge that the natural world supplies important inputs and waste sinks for the economic system. However, incremental degradation of this natural capital, it is argued, seldom leads to the loss of unique services; all have reasonable substitutes.

Recall that sustainability was defined earlier as non-declining welfare for the typical member of a future generation. The neoclassical argument is that investment in created, human-made capital can (and tends to) generate a flow of services improving quality of life which at least offsets the loss of services provided by degraded natural capital. This concept has been dubbed *weak sustainability*.

Neoclassical economists often use the example of whale oil or copper telephone wires. As these resources became relatively scarce and their prices rose, petroleum and fiber optics emerged as substitutes. What about a harder case like the loss of climate stability due to global warming? Neoclassical economists respond, first that as greenhouse gas emissions are regulated, the externality is internalized, and the price of carbon dioxide (CO_2)-based services (like gasoline-powered automobiles) rise, then new low-CO_2 technologies will emerge. Moreover, advances in agricultural techniques will insure adaptation to a changing climate, and dikes can be built to hold back sea level rise. Clearly there will be losers from climate change, but on balance, the argument goes, living standards for the typical person on the planet will continue to rise even in the face of moderate climate change.

Neoclassical economists in this context are technological optimists. This means that they believe that in well behaved market economies (those in which negative externalities have been internalized via IB regulations like pollution taxes or marketable permit systems), substitutes will emerge for scarce (and increasingly expensive) natural resources and environmental waste sinks. System sustainability is thus assured by assumption.

Technically, this means that the economy will display a positive rate of growth of *per capita* net national welfare, the familiar GDP measure of economic output adjusted downwards to reflect the costs of economic growth. If net national welfare, which balances the benefits of increased material consumption against the attendant environmental and social costs, is growing on a *per capita* basis, than by definition, the well-being of future generations is also rising (Goodstein, 1999a, Chapter 6).

While (weak) system sustainability is generally assumed in the technologically optimistic neoclassical framework, sustainable decisions at the micro level should be made using BC analysis. For example, when considering whether

or not to build a coal plant, one should compare the discounted stream of measurable monetary costs (material and environmental) over the expected life of the plant, against the discounted stream of measurable monetary benefits (cheaper power). If the benefits exceed the costs, than building the plant would be sustainable in the weak sense, because doing so would, on net, raise the welfare of the typical member of future generations.

Future costs and benefits are discounted in BC analysis to reflect the opportunity cost of productive foregone investment. For example, the value of $100 received in 10 years (ignoring inflation) is a lot less than the value of $100 received today. If the interest rate were 10%, I could invest that $100 today and have $260 in 10 years. Conversely, to have $100 on hand in 10 years I would need to bank only $39 today. This figure of $39 is called the *Present Discounted Value* of $100 received in 10 years, if a 10% interest or discount rate is available. While discounting makes sense for individual financial decisions, at the social level it can generate perverse outcomes (*see* Discounting, Volume 5).

To illustrate, suppose we are considering installing a filter on our coal plant that will generate a one-time-only benefit of $100 million 100 years from now. At a discount rate of 10%, a $100 million benefit gained 100 years from now is worth only $7200 today. The logic of BC analysis thus suggests that we should not spend a measly seven thousand dollars and change today to yield a benefit of $100 million to our great grandchildren. Why? Because if we put the money in the bank, future generations would have more than $100 million on hand.

The problem is that, for real world projects subject to BC analysis, we do not intend to put net savings in a trust fund; the alternative is instead to spend it elsewhere in the economy (say, to reduce energy prices from the coal plant) where it may or may not yield a 10% rate of return to society as a whole. While discounting makes obvious sense on a personal level for short time horizons, it breaks down for actions yielding a stream of social benefits far into the future.

On the flip side, not discounting at all also generates perverse outcomes. Consider a project that yields $1 worth of benefits every year, forever. Such a project has infinite value, and would thus seem to be worth sacrificing the entire planet's output to finance. Given these two extremes, there is a lot of debate over the proper approach to discounting future benefits and costs (Portney and Weyant, 1999).

If indeed the analysis is sensitive to the choice of a discount rate, or else tries to weigh controversial benefits such as lives saved or biodiversity preserved, then uncertainties can easily grow large enough to render determination of a (weakly) sustainable outcome at the project level difficult, if not impossible.

SUSTAINABILITY: THE ECOLOGICAL VIEW

In contrast to neoclassical economists, ecological economists are technological pessimists (*see* Ecological Economics, Volume 5). Tracing their intellectual lineage explicitly to Malthus, ecological economists have no faith that technological substitutes for important natural resources, such as climate stability, will be forthcoming from real-world market systems. Thus, ecological economists would reject a coal plant following the logic that CO_2 emissions are already destabilizing the global climate. Essentially, ecological economists argue that for important resources such as fresh water, ultraviolet protection, biodiversity and climate stability, the future consequences of current resource degradation are too uncertain to countenance the use of BC analysis.

Instead ecological economists argue for what they call the Precautionary Principle (*see* Precautionary Principle, Volume 4). To preserve the welfare of future generations, therefore, unique forms of natural capital should be protected *unless the costs of doing so are prohibitively high* (Ciriacy-Wantrup, 1968; Daly, 1996). This strategy of protecting natural capital has the advantage of not relying on the development of uncertain substitutes to insure (weakly) sustainable outcomes. Thus following the Precautionary Principle promotes strong sustainability from an ecological perspective, by insuring that future generations will not be impoverished by the loss of natural capital. Moreover, the argument is often simultaneously advanced that the cost of protection will not be so high as is frequently claimed (Laitner *et al.*, 1998).

Along this line, ecological economists point to survey evidence suggesting that, in developed countries, broad growth in material consumption in fact buys very little increases in societal happiness. This occurs, it is argued, because beyond a basic level, utility from consumption depends on relative rather than absolute levels of consumption. To the extent that this is true, environmental quality is being sacrificed only to feed a rat race in which human welfare does not rise with increased material consumption, clearly an unsustainable state of affairs (Mishan, 1968; Howarth, 1996).

Which view is correct? Neoclassical economists argue that the ecological position is too extreme. They insist there are trade-offs, and that we can pay too much for a pristine environment. Resources and person-power invested in reducing small cancer risks or preserving salmon streams, for example, are resources and people that cannot be invested in schools or health care, also of value to future generations. BC analysis is needed to obtain the right balance of investment between environmental protection and other goods and services. Moreover, in the sustainability debate, neoclassical economists argue that history is on their side: Malthusian predictions have been discredited time and time again.

Indeed, in recent years, some scientists have made stunningly bad forecasts regarding looming resource shortages. The problem with these predictions, as with Malthus's original one, was that they dramatically underestimated the impacts of changing technologies. Neoclassical economists point to these failed predictions to support their basic assumption that natural and created capital are indeed good substitutes: we are not running out of natural resources or waste sinks.

Ecological economists respond that history is not a good guide for the future. One hundred and fifty years after the beginning of the industrial revolution, the argument is that accumulating stresses have begun to fundamentally erode the resilience of local and global ecosystems upon which the economy ultimately depends. Indeed, ecological economists have largely shifted their 1970s concerns about running out of nonrenewable minerals and oil to concerns such as: biodiversity, fresh water, environmental waste sinks, and productive agricultural land. While ecological economists stretching back to Malthus have indeed done their share of crying wolf, this does not, of course, mean the wolf is not now at our door.

The neoclassical and ecological perspectives differ dramatically in their assessment of the likelihood of sustainable outcomes from real world market economies. Nevertheless, both perspectives are economic: both accept the common definition of sustainability offered above; both are grounded in broadly utilitarian philosophy, and both deal in the currency of trade-offs. In addition, this is a debate about ends, not means. Ecological economists prefer that resource development or environmental degradation be regulated according to a precautionary principal; neoclassical economists prefer a BC test. When it comes to means, however, economists from both schools would prefer to see greater reliance on incentive systems than is provided by existing environmental and resource regulations (see below).

THE CURRENT REGULATORY SYSTEM

Perhaps the most striking aspect of environmental regulation at the national level is its brief history. As recently as 1970, for example, the US had no major federal legislation controlling the discharge of pollutants into the air and water, no national regulations covering the disposal of hazardous waste onto land, no process for reviewing new chemicals, only a limited procedure for registering new pesticides, and no protection for endangered species.

Beginning in the early 1970s, countries around the world began adopting national environmental protection legislation. Most of these laws required government agencies to develop detailed prescriptive regulation for several different types of industrial polluters. Economists have since dubbed this approach CAC regulation. CAC involves two parts. The first is uniform emission standards. All similar sources are commanded to meet identical emission levels. The control part of the name refers to the technology-based regulatory approach employed by much current regulation. Regulators specify, at a high level of detail, precisely which technologies firms must employ to reduce emissions.

While this initial effort to internalize externalities was effective in many regards, CAC regulation is generally not cost-effective, either in the short run or the long run. (By cost-effective is meant achieving a given pollution reduction goal at the lowest possible cost.) Uniform emission standards raise costs in the short run, since all plants must meet the same reduction targets, regardless of differences in the cost of doing so. Technology-based regulation raises costs in the long run by stifling incentives for innovation in new pollution control technology. These factors have led most economists to advocate a greater use of IB regulation like emission charges or marketable permit systems.

More broadly, regulation has been criticized as ineffective on a variety of grounds:

- regulatory design and enforcement is subject to significant political influence;
- regulation addresses symptoms in a piecemeal way, rather than underlying causes in a comprehensive way;
- regulations must be continually tightened or else they will be overwhelmed by economic and population growth;
- regulation has already picked off the easy targets: large, stationary pollution sources. Increasingly, pollution is arising from mobile sources like cars, and non-point sources like run-off from streets and farms.

These factors have led some economists to call for greater government support for the development of technologies which are much cleaner in the first place.

Before discussing calls for reform, however, it is important to note that CAC systems have significant achievements to their credit (Goodstein, 1999a, Chapter 14). In the United States for example, in spite of the fact that economic activity more than doubled from 1970 to 2000, the general urban air pollution picture has actually improved, dramatically for lead. In addition, large reductions in air toxins have been recorded over the last decade. Industrial emissions of some water borne pollutants have dropped dramatically and, overall, water quality has improved a bit beyond 1970 levels. Regulation of hazardous waste is likely to prevent the development of future *Love Canals*. And the rising cost of disposal, along with the right-to-know regulations, and the potential for Superfund liability is beginning to focus corporate attention on reducing waste through pollution prevention. Particularly nasty new pesticides are not likely to make it through the EPA's initial screen, and under prodding from Congress, the agency will restrict the use of the

worst of the existing pesticides in the first few years of this century. Finally, only a few listed species have slipped into extinction. The fact that regulation has managed to hold the line against economic growth is in itself an impressive accomplishment.

DOING BETTER: INCENTIVE-BASED REGULATION

It is straightforward to see how uniform standards and government mandated technology requirements under CAC raise the costs of regulation. In the case of uniform standards, consider two neighboring oil refineries. Refinery A, which has the ability to reduce emissions of say, nitrogen oxides, at very low-cost, is nevertheless expected to meet the same standard as next door refinery B, a firm with very high costs of reduction. The reason this is not cost-effective is simple: the same overall emission reduction (and local air quality) could be achieved at lower cost by having the low-cost firm meet a tighter emission standard, while relaxing the standard for the neighboring high-cost firm. Similarly, in the short run, a single technological mandate is unlikely to provide the cheapest pollution control solution for different firms all over the country. This lack of flexibility inherent in centralized, technology-based regulation raises costs (Goodstein, 1999a, Chapter 16).

However, long-run cost effects are more important. Technology-based regulation works against technological improvement in several ways. First, once a firm has installed the government-mandated technology it has no incentive to do better. Second, the firm actually has a positive incentive not to do better. If, for example, it discovered a better technique for pollution reduction, and the EPA then decided to deem this new technology to be the standard, the firm might legally be required to upgrade its pollution control technology at other new facilities. Firms have a distinct incentive to keep the agency from upgrading the state-of-the-art technological standard. Finally, if in spite of these obstacles, firms do seek an innovative, non-approved approach, they must first obtain regulatory clearance to do so.

IB regulation provides an alternative to CAC. There are two kinds, closely related. The first is a pollution tax (also known as an effluent or emission charge or fee). For example, to reduce power plant emissions of carbon dioxide, which fuel the greenhouse effect, society could institute a tax on emissions of, say, $25 per ton of CO_2. Alternatively, one might achieve a roll-back through a marketable permit system (also known as a tradable permit or cap-and-trade system). Here CO_2 permits would be issued or auctioned to polluters only up to a certain target level of overall emissions. These permits could then be bought and sold by others, again putting a market price tag on pollution (*see* **Tradable Permits for Greenhouse Gases**, Volume 4).

The first effect of IB systems is to eliminate uniform emission levels at different sites. Plants facing high costs of reducing pollution will cut back a little and either pay the emission charge or buy additional permits. Plants with low costs will cut back a lot, and either save on pollution taxes, or make money by selling some permits. Overall pollution levels can be set the same as under CAC regulation, but the compliance costs will be less as firms are given greater flexibility, as well as incentives to make emission cuts at the lowest cost sites.

The second beneficial aspect of IB regulation is that it provides a flexible framework for innovation. Firms can install any pollution control technology they desire. Moreover, IB regulation also establishes continuous incentives for technological progress. CAC regulation does not penalize firms for any pollutants they emit once they have installed the technology mandated by the government; by contrast under IB regulation firms pay for every pound of pollution coming out of the stacks. They do this directly under an emission charge system, but pollution bears a similar price under a cap-and-trade system. By reducing pollution towards zero, firms can make money by selling their excess permits.

Textbook emission charge systems are not often found in the real world, perhaps because, as new taxes they are politically difficult to institute. By contrast, cap-and-trade systems are increasingly popular. The biggest success to date has been the acid rain program in the US. Initiated in 1995 to control the emission of sulfur dioxide from power plants, the program has functioned largely according to plan. SO_2 emissions have been reduced by about half, and the program has generated significant cost savings (Schmalensee *et al.*, 1998).

A couple of caveats are in order regarding IB systems. First, they only work well for pollutants that do their damage regionally or globally. If pollutant damage is local, than a simple IB system will generate hot spots: high pollutant damages around high cost-of-reduction plants. Second, the government must have good monitoring and enforcement capabilities. Firms must either pay the effluent charges due, or face stiff fines for any pollutants emitted above their permitted levels. In some cases, CAC regulation may be easier to monitor and enforce than an IB approach (Goodstein, 1999a).

DOING BETTER: PROMOTING CLEAN TECHNOLOGY

Regulation, whether CAC or IB, is designed to internalize externalities, and force firms and consumers to bear the social costs of pollution. Most economists agree that a shift towards greater use of IB regulation would help reduce

the costs of environmental protection, and thus make it politically easier to achieve. But is getting the prices right through regulation (whether IB or CAC) enough to insure a sustainable economy?

A second strategy is to directly promote the development and diffusion of clean technology: fuel-cell vehicles, solar and wind powered electricity, energy and water efficiency technologies, alternative agriculture, recycling (Goodstein, 1999a, Chapter 18). Rather than rely solely on controlling pollutants at the end-of-the-pipe, advocates of this approach argue that government should promote the use of technologies which reduce polluting inputs and processes in the first place. Technologies can be advanced through policies like R&D, consumer subsidies, and public procurement contracts. So called technology-forcing regulations can also promote new options; examples in the US include the Corporate Average Fuel Efficiency (CAFE) standards, energy efficiency standards for appliances, and the California zero emission vehicle requirements.

From a theoretical point of view, government efforts to influence the direction of technological progress can be justified by what economists call *path dependence* (Arthur, 1991). This theory maintains that current production technologies (for example, US reliance on private automobiles for urban transportation) represent only one possible path of development. A potentially cost competitive alternative in this case might be mass transit, dominant in many European and Japanese cities.

The path a society chooses depends on a variety of factors, including the relative political strength of the conflicting interests, chance historical circumstance, and, of course, consumer preferences and relative production costs. In the auto example, the US government's decision to construct the interstate highway system beginning after World War II, which in turn promoted suburban development, provided the decisive advantage to private transport.

However, once a path has been chosen, other paths are closed off. This happens for three reasons. First, infrastructure and R&D investments are increasingly directed towards supporting the chosen technology, and diverted from the competing path. Second, the chosen technology is able to exploit economies of scale to consolidate its cost advantage. Third, complementary technologies develop which are tailored to the chosen path, further disadvantaging the competing path. In the transportation example, this would include the sprawling retail and housing patterns of US cities, which now virtually require a private vehicle for access.

Path-dependence theory suggests that once a path is chosen, there is no easy way to switch tracks. However, in retrospect, we can see that technological choices have social consequences: the adoption of private transport, for example, has borne a substantial environmental cost. Thus, the role of government is to try and influence the current market driven process of technological development towards a path consistent with a sustainable future. Note that this theory assumes that governments in modern capitalist societies already necessarily play a major role in shaping technological change through infrastructure decisions and subsidy policies; the key here is to insure that the role is a positive one.

Under a clean technology strategy, promotional efforts should be limited to technologies which are close to commercial development, generate a quality of service and have long-run production costs comparable to existing technologies, and are environmentally superior. Each of these requirements must be met, otherwise, the technology will not spread rapidly, and little environmental benefit will result. But given these conditions, why aren't private entrepreneurs developing them in the first place?

The answer lies in the short-term bias of market actors discussed above. Simply because clean technologies are potentially cost competitive does not mean that they are more profitable than existing technologies. Entrepreneurs tend to introduce products which fill a market niche and provide at least temporary monopoly profits (computers, VCRs, cell phones). Clean technologies, by contrast, generally are not offering a new product; rather they go head-to-head to with an existing, well-established technology in a mature industry: electricity or transportation, for example. Thus they must enter an already competitive field, where only normal profits can be expected. The only clear-cut advantage that clean technologies have is in their environmental impact. While this may provide some marketing leverage, it generally will not guarantee high profitability.

Under normal market circumstances, new technologies often take a substantial time to develop a widespread following. This is due to consumers' lack of knowledge about the advantages of the new technology, as well as differences in consumer needs. The transition to any new technology requires a marketing commitment to overcome this lack of information. Marketing expenses are sunk costs, that is, costs that cannot be recovered if an investment fails. The higher the sunk costs associated with an investment, the riskier it becomes.

Clean technologies face particularly high sunk costs (and thus high risk) because they do not market themselves by offering a service that consumers do not already have. Instead, clean technologies need to woo consumers from the use of the existing technology. While clean technologies offer comparable services, they also tend to require users to learn new consumption habits. This requires a big investment in marketing, which cannot be recovered if the business fails.

In summary, many clean technologies are unlikely to be highly profitable in the short to medium term; as a consequence, private sector investors show little interest. Government policy can change this equation by absorbing

some of the risk associated with the introduction of these new technologies, nurturing infant industries.

There is disagreement among economists as to how far government should move in this direction. Basic scientific R&D generates positive externalities; not all of the benefit of innovation is captured by the inventor. For that reason, most economists agree that support of basic science is an important governmental role. Beyond that, however, while some argue that government should support significant investment in clean technologies, others maintain that government should do nothing. In part this has to do with disagreement over the extent to which the short-term bias of market economies, discussed above, has on sustainable outcomes. Those opposed to government support for technology feel that, if the prices are right (that is, if externalities have been internalized), then the private market place will bring new technologies on line soon enough to avoid unsustainable levels of environmental damage.

The disagreement also has to do with political economic views on the efficacy of government intervention into the economy. Opponents of clean technology promotion argue that the government is likely to promote the wrong technologies, and that these decisions are better left to a decentralized market process.

THE ECONOMICS OF THE GLOBAL ENVIRONMENT

This essay has so far outlined the theoretical relationship between *laissez faire* markets and sustainability, and discussed policy options at the national level for promoting sustainability. We now turn our attention to global environmental challenges: the complex links between widespread poverty in poor countries (working in part through high population growth rates), high levels of consumption in rich countries, and environmental degradation at both the global level and in the less developed world. Finally, we end with a look at the economics of global environmental agreements.

In rich countries, it is commonly assumed that environmental quality can only be improved by sacrificing material consumption. In poor countries, by contrast, a broad-based growth in income will, in many respects, tend to improve the quality of the environment. There are four close connections between poverty and the environment (World Bank, 1992).

1. For poor people, many environmental problems are problems of poverty. The biggest environmental health threats facing most people in poor countries are unsafe drinking water, compounded by inadequate sewage facilities, and urban air pollution. Exposure to indoor air pollution (smoke) from cooking and heating sources ranks close to industrial and auto air pollution as a concern.
2. Poor people cannot afford to conserve resources. Out of economic necessity, poor people often put an unsustainable burden on the natural capital in their immediate environment. Urban residents scour the immediate countryside for fuel (firewood or animal dung) leading to deforestation or the elimination of fertilizer sources. Landless farmers are pushed into over farming small plots, farming on steep mountain slopes that soon wash out, or farming in clear-cut rain forests incapable of sustaining agriculture.
3. Richer people demand more pollution control. As *per capita* income rises in a country, people begin to express a more effective demand for pollution control. Partly this has to do with education. As income rises, so do levels of awareness regarding environmental threats. Partly, it has to do with expanding democracy. As income rises, political participation tends to increase. As a result, people are provided with the opportunity to express a political demand for pollution control. Partly, it has to do with a shift in industrial composition: wealthier countries rely more on services and other relatively clean industries, while less developed countries have more basic manufacturing and mining. Finally, the relationship can be explained by relative risk considerations: when life spans are short due to inadequate nutrition or access to basic health care, concerns about respiratory, neurological and reproductive diseases, or cancer from pollution, are dampened.
4. Population growth slows with increased income. The final link between poverty and the environment lies in income growth as a means of population control, discussed later.

These four interconnections between poverty and the environment reveal that, in poor countries, one need not trade-off rising material living standards for improved environmental quality. In fact, the only effective way to improve environmental conditions is to alleviate the tremendous poverty faced by many of the people in these nations.

POPULATION AND DEVELOPMENT

Higher incomes tend to be associated with lower population growth rates. While the relationship is not hard and fast, for example, welfare families in America are not significantly larger than the average, it holds as a general rule, both across countries, and within countries. Many factors go into determining family size; religious and cultural norms obviously play a prominent role. Yet the strength of the poverty–fertility relationship suggests that economic factors are quite important as well (Dasgupta, 1995).

In poor countries, children provide two important economic functions: health and old age insurance, and after early childhood, a potential supplement to family income.

Given limited resources, a family could potentially obtain comparable economic benefits following one of two approaches: a high investment strategy with one or two children, or a low investment strategy with many children.

The high investment strategy would involve focusing all available resources on one or two children: insuring that they survive infancy, are provided with a healthy diet, and go on to attend school. Such a child might well land a good job, and increase family income substantially. For poor people with limited resources and restricted access to public services, the high investment strategy is very difficult to pursue. Moreover, it is tremendously risky. Suppose that after five years of intensive investment, a single child dies. Yet, as income rises, the high investment strategy begins to be more attractive. Resources for the long-term (15–18 year) investment are more readily available, and access to better health care means that the chances of premature death decline.

This BC model of family size is a very crude one, omitting as it does very important issues of culture, kinship, religion, love and affection. Yet it does a good job explaining the strong relationship between poverty and fertility observed in many places around the world. In particular, because there are *good economic reasons* for poor people to have large families, simple provision of low-cost birth control is unlikely to solve the population problem (though it would certainly help). Can we use this BC model to suggest other effective policies for controlling population growth?

Balanced Growth and Provision of Social Services

The poverty–fertility relationship seems to provide a straightforward way to control population: eliminate poverty! Unfortunately, if nations were able to do this easily, they would have done so already. It does remains true, however, that balanced and rapid economic development which raises the material welfare of the poor majority is one of the most effective population control measures available. In addition to balanced growth, another way to reduce poverty and thus population growth rates is through the form of publicly provided social services: education, health care, and public pension plans.

Reduced Infant and Childhood Mortality

Improved public health is an important factor in reducing long-run population growth rates. The BC approach to family size suggest that improved health care would help slow population growth for one principal reason: the risk associated with investing in a child's health and education would be reduced, encouraging families to substitute quality for quantity.

Education

The economic model of family size tells us that population growth will slow when parents follow a strategy of high investment in their children. A key element making such a strategy possible is access to education. This is true for three reasons. First, the availability of education directly lowers the cost of pursuing a high investment strategy to all parents, educated and uneducated alike. Second, as parents become educated themselves, a strategy of substituting quality for quantity also becomes easier, since the parents can provide guidance to the children.

Finally, as parents become educated, their wages tend to rise. This increases the opportunity cost of parents' time, making a low-investment strategy less attractive. This is true because a low investment, quantity strategy requires a bigger commitment of time devoted to child-rearing than does a high investment, quality strategy. Another way to look at this is that, as the parents' wages rise, family income and economic insurance are better served by parents working than by raising more children.

For this reason, education is particularly important for women, since they do most of the child rearing. One of the best ways to control fertility is to have women participating in the *modern sector* of the economy. All poor women work. However, employment in agricultural or household labor does not appear to reduce fertility. As the opportunity cost of the woman's time rises, a quantity strategy becomes less and less attractive for the family as a unit.

Education for women appears to have a strong impact on fertility control for other reasons as well. To this point, we have treated the family as a homogeneous unit, yet men and women play different roles in the family, and may have different ideas about the desirability of limiting family size. In the developing world, as in rich countries, the responsibility for taking birth control measures (whether abstinence, prolonged breast feeding, or a technological approach) generally falls on the woman. Thus the direct consumers of birth control devices and fertility control information are generally women, providing another argument for improved female education (*see* Ecofeminism, Volume 5).

More importantly, however, most of the world's societies are male dominated, patriarchal cultures. In such societies, women often must obtain approval from their husbands in order to control their fertility. This distinction is important, because holding all things equal, it is probably true that women prefer to have fewer children than do men. This is likely for a number of reasons: women do the vast majority of the hard work involved in child rearing; child rearing interferes with women's other economic activities; and child birth represents a significant health risk for many women. Thus, policies which strengthen women's status and bargaining position within the family itself, for example, better education or access to paid employment, are likely to have important effects on fertility decisions, independent of their impact on overall family income and economic insurance.

Family Planning

Having argued above that poor people may have good reasons for having large families, it is also true that a big obstacle to pursuing a high investment strategy is lack of access to family planning services. There remains a large unsatisfied demand for birth control worldwide (World Bank, 1992).

GLOBAL CONSUMPTION AND TRADE

In discussions of population pressures on the environment, it is important to recognize that the environmental damage people do depends not only on absolute numbers, but also on the natural capital depleted and waste products generated by each person. As an upper middle class citizen of the US, I consume more than *100 times the resources* used by the average individual from a poor country. The point here is not to induce guilt about af uent lifestyles, but rather to recognize that one needs to focus as much attention on reducing the environmental impact of high consumption in rich countries, as is paid to reducing population growth in poor countries.

Moreover, although the population problem is concentrated in poor countries, through legal and illegal immigration, poor-country population pressure spills over into af uent countries. And while today the consumption problem is centered in rich countries, this too will begin to change as a growing number of poor country residents aspire to the consumption levels found in rich countries.

Because inhabitants of rich countries are responsible for over two-thirds of global economic activity, at least two-thirds of global pollution can be laid at our doorstep. The western European countries, the US and Japan comprise about 15% of the world s population, but they consume 71% of the world s output (World Bank, 1992, Table A.2). As a result, rich-country consumption has to date been responsible for most of the global atmospheric pollution: global warming, ozone depletion, acid rain, and radioactive contamination. Rich countries have had by far the biggest impact on polluting and over- shing the oceans.

In addition to generating global pollution problems, there is a second element to the consumption pollution link. High levels of consumption demand in rich countries have been responsible for an unsustainable draw-down in environmental quality and the stock of natural capital in many poor countries. Many poor countries rely on the export of primary resources or agricultural commodities to earn money for imported fuel, food, consumer goods and weapons. In principal, this trade is environmentally sustainable. However, weak sustainability requires that any draw down in the stock of natural capital (whether oil or mineral reserves, rainforest resources, top soil, or air and water quality) be compensated for by investment in created capital.

The overwhelming demand for resources in rich countries (ranging from gasoline, to steel, to bananas, to beef) has in many cases depleted the natural capital stock in poor countries, without commensurate investment in created capital. Why has this occurred? Historically, colonial governments tended to drain resource-generated wealth from their colonies, investing little in human capital or infrastructure. In the post-colonial period, falling relative prices for primary resources, low taxes on politically powerful resource-based industries, and high levels of spending on military and imported consumption goods by the ruling elite have constrained investment in created capital. Finally, the burden of debt repayment has led to a ow of created wealth from poor to rich countries over much of the last 20 years.

This is not to say that trade in agricultural commodities, or any other goods, is on balance, bad for the environment. Rather, to insure sustainability, the gains from trade must be invested in created capital suf cient to offset the draw-down in natural capital. If they are not, than rich-country consumption leads to unsustainable development in poor countries as surely as does rapid population growth.

What is the relationship between trade and the environment? The pro free trade argument is that trade leads to economic growth, economic growth reduces poverty, and as we saw above, a reduction in poverty is a critical precondition for environmental protection in poor countries (Bhagwati, 1993). Poor countries often support trade liberalization through multilateral agencies like the World Trade Organization (WTO) in order to keep the rich countries from unilaterally imposing tariffs or other trade restrictions. International trade and investment can also facilitate the transfer of cleaner technologies from rich to poor countries.

These positions clearly have merit. Yet critics respond, rst, that trade does not always lead to growth because, as argued above, suf cient pro ts from trade are not reinvested in poor countries to compensate them for their loss of natural resources. Second, even if economic growth occurs, the environmental bene ts which accompany growth can be overwhelmed by the increase in pollution from export production, leading to a decline in environmental quality in poor countries.

Finally, critics charge that environmental regulations in rich countries will be weakened by liberalized trade and investment, as business mobility increases, and legal challenges are lodged by international competitors (Daly, 1993). On the former point, economists have found that in fact, very few businesses have ed from developed to underdeveloped countries to escape stringent environmental regulations (Goodstein, 1999b). This appears true in part because even for heavily regulated rms, environmental costs seldom rise above 2% of total business costs. Moreover, much pollution control technology is imbedded in modern plant design. A new chemical plant built by a multinational in Chile will in fact look a lot like one built in Texas. When

firms do head to the South, the reason is, overwhelmingly, low wages.

On the second point, free trade agreements can indeed bind the hands of environmental regulators, since they give foreign governments the ability to challenge certain regulations as trade barriers. In 1999, the US acting on behalf of Ford and Daimler-Chrysler, challenged a Japanese government initiative designed to reduce CO_2 emissions from automobiles. The law required that new mid-sized cars sold in Japan have engines as efficient as the most efficient on the market, which were then produced by Mitsubishi. Under the rules of the WTO, the US sought to have the law overturned as a barrier to trade. If the WTO rules in favor of the US, Japan will have to rescind the law or face trade sanctions (Wallach and Sforza, 1999).

Is free trade good or bad for the environment? More liberal trade is generally championed by economists because it is believed to increase efficiency, and in the long run, raise material living standards across the board. However, the process of globalization is crafting a new set of rules that will benefit some more than others, and it is also certain to generate many losers. The environmental challenge is to harness the efficiency gains generated by trade into domestic investments in poor countries, thereby helping create a sustainable future. From this perspective, agreements promoting more trade should be viewed as a means to an end (stabilizing population growth, enhancing food security, transferring sustainable technology, and conserving resources) not as an end in itself. Yet at this point, trade agreements have only just begun to acknowledge environmental and sustainability concerns.

THE ECONOMICS OF GLOBAL AGREEMENTS

Beyond poverty, overpopulation, and the growth of environmental impacts from global over-consumption, transboundary pollution problems present serious threats to sustainability. Global warming, ozone depletion, acid rain, and exploitation of the oceans, Antarctica, and even outer space, are all processes occurring outside the jurisdiction of a single nation. There is no international environmental protection agency with the authority to regulate exploitation of the global commons.

To address these problems, nations have begun to negotiate international agreements. However, economic theory suggests that effective international agreements are hard to develop. From an economic point of view, an international pollution control agreement is a public good, which must be provided voluntarily by the private nations of the world. Public goods are goods which are enjoyed in common; a classic example, if dated, is the warning service provided by a lighthouse. Technically, economists describe public goods as non-excludable. Once in operation, it is impossible to exclude any passing boat from utilizing the warning beacon provided by the lighthouse. Public goods tend to be under-supplied in a free market economy precisely because many of those who benefit can free ride if the good is provided at all. This than justifies government in taxing the beneficiaries, and then subsidizing the provision of public goods: for example, basic scientific research.

Reducing global warming is a public good, because there is no way to exclude free riders from enjoying the climate stabilization benefits provided by a treaty. However, in this case, there is no international government to insure that the sustainable level of protection is provided.

The public-good nature of environmental treaties has two implications. First, treaties will tend to be too weak from a BC point of view, since signatory nations are reluctant to reveal and commit their true willingness-to-pay in the bargaining process. Second, once signed, nations will have a strong incentive to cheat on the agreement. Unilateral cheating is another way to free ride on the pollution control efforts of others. Of course, if everyone cheats, the agreement will collapse.

Beyond free riding, agreement on burden sharing is difficult to achieve. In principle, each country might contribute their true willingness-to-pay for a treaty. This willingness-to-pay in turn would depend on both the benefits received, and ability to pay. Both of these might vary widely between nations. For example, low-lying Bangladesh, has a tremendous stake in slowing global warming, and preventing a devastating sea-level rise. Yet the country is poor, and would have a difficult time financing strong measures to reduce CO_2 emissions. On the other hand, a land-locked, wealthy country like Switzerland has a high ability to pay, but may have fewer immediate interests at stake.

A poor country's willingness-to-pay to join an agreement will typically be much smaller than that of a rich country, simply because it has a much lower national income. Yet poor-country participation will often be vital. For example, if China were to further industrialize using its vast coal reserves, global warming would accelerate considerably. Given China's low willingness to pay for a reduction in global warming (as a result of its low income), a compensation fund would have to be established for China to sign a greenhouse treaty. Those with a high willingness-to-pay (typically rich countries) would have to pay for China to adopt less polluting and expensive energy sources. Otherwise, it would not be in China's interests to sign the treaty.

If each nation did contribute its true willingness-to-pay, then the agreement process would generate an efficient level of global pollution control. However, a country's underlying willingness-to-pay for an agreement is not a well-defined thing in the first place, and is certainly not transparent to negotiators from other nations. Therefore, each nation's bargainers will have an incentive to understate

its true interest in a treaty in the hopes that others will shoulder more of the burden. In the extreme, a country might not sign a global warming or other environmental treaty at all, but still benefit from the efforts of other nations, acting as a pure free rider.

While the theory of public goods predicts that international environmental treaties will be both weak and susceptible to enforcement problems, agreements nevertheless do get signed and efforts are made to insure compliance. The 1986 Montreal Protocol to protect the ozone layer, in spite of the theory sketched out above, has been a remarkable success story. This was due to the perception on the part of many countries of a clear and present danger; relatively few pollutant sources; and the realization (after the treaty was signed) of relatively low compliance costs (Goodstein, 1999a, Chapter 22).

By contrast, the struggle to implement the 1997 Kyoto global warming accord reflects much more of the difficulty in assigning burden sharing, and the free rider phenomenon. This agreement was signed by all of the developed countries, including the US, and calls for a reduction in greenhouse gas emissions to below 1990 levels. Following the model of the Montreal Protocol, poor countries were not required to participate at the outset. The rationale for this was two-fold: developed countries had caused the problem, and they had the resources to develop the alternative energy technologies needed for large-scale reduction in carbon emissions. However, there has been strong opposition in the US Senate and from President Bush to treaty ratification: not surprising, since the US is the biggest greenhouse gas polluter. The US Senate argues that poor countries should also be included in the treaty and required to reduce emissions at the outset. This position, if it is maintained, threatens to scuttle the entire agreement (Goodstein, 1999b).

CONCLUSION

This essay has provided a brief introduction to the economic analysis of global environmental change. For economists, the goal of sustainability (an improved quality of life for most people) is well defined, if hard to operationalize. Within this utilitarian framework, an economist will ask three questions. First, given that pollution and resource degradation are a by-product of economic output, how much pollution and resource degradation are consistent with a sustainable future? Second, once the pollution reduction or resource preservation target is set, how can we achieve our goal at the lowest possible cost? And finally, how can we address global environmental problems, including the pressures placed on the environment by widespread poverty; high population growth rates; unsustainable trade patterns; and the need for more effective global agreements? As indicated, there is often lively debate among economists regarding the right answers. But what we do agree on is the centrality of these three questions.

Ecological Economics

RICHARD B NORGAARD

University of California at Berkley, CA, USA

Economists, ecologists, and scholars from a variety of other disciplines have organized an intellectual community known as ecological economics. The International Society for Ecological Economics (ISEE) was established in 1989, in response to a concern that the dominant ways of economic thinking have fostered particular forms of global change with detrimental social and environmental impacts. The constitution of the Society states:

The purpose of the Society is the advancement of our understanding of the relationships among ecological, social, and economic systems and the application of this understanding to the mutual well-being of nature and people, especially that of the most vulnerable, including future generations.

Note that ecological economists broadly stress the interaction of multiple systems and the "mutual well-being of nature and people", putting the emphasis on the interaction, rather than people or nature alone. The concern, however, is also focused on the "most vulnerable", again whether people or other species.

Expanding on this general statement, ecological economists share three general concerns that are neither adequately recognized in dominant academic and professional economic circles, nor appropriately considered in political economic discourse. These are: (1) that economies must be understood as operating within the larger biogeochemical Earth System receiving energy from the sun; (2) that environmental sustainability depends on viable social systems; and (3) that progress toward the mutual well-being of nature and people is being thwarted by excessive material consumption on the one hand, and excessive material inequality on the other. Ecological economists are methodologically eclectic, using ecological reasoning and both dominant and alternative economics in their search for better understanding of the interrelations between people and their environment, for indicators of sustainability, and for ways of bringing individual human behavior into conformity with collective human goals. While the concern with excessive consumption and equity clearly makes ecological economics an alternative community for economists and ecologists in rich countries, these same concerns make ecological economics a very comfortable community for scholars addressing sustainable development in poor countries.

THE NATURE OF ECOLOGICAL ECONOMICS

Many have tried to define ecological economics, few have reached the same explication (see, for example, Martinez-Alier, 1987; Costanza, 1989; Costanza *et al.*, 1997; Soderbaum, 2000). This difficulty, of some concern both within and beyond the field, arises for a variety of reasons. First, many researchers who self-identify as ecological economists use the models and methods of more conventional environmental economists. This has led some environmental economists to argue that there is nothing new in ecological economics. Yet the difference is clear. Ecological economists, as a whole, also use other models and methods, and actively discuss the strengths and weaknesses of environmental economic models in the contexts of the others. Second, since its modern beginnings, ecological economists have been searching for effective ways to understand and convey the importance of justice in the context of environmental sustainability and human dignity. Third, ecological economists have been grappling with how environmental problems require both new ways of understanding science and new ways of joining knowledge distributed among scientists, practitioners, and lay people to effect collective action. These latter two broad facets of ecological economics perplex both new entrants to the field and external observers who try to logically fashion ecological economics out of ecology and economics as narrowly defined. Fourth, and stemming from the first three, there is mild disagreement over whether (a) ecological economics should be striving for a new paradigm, a new set of integrative models, systems assumptions, and empirical methods, or (b) it should, or must, remain a large umbrella under

Box 1 Working Assumptions of Ecological Economics

- economies and the global economy overall require energy, materials and diverse genetic/species/ecosystem patterns and reproductive capacities provided by healthy natural systems;
    - current levels of energy use, material flows, and genetic/species/ecosystem loss are both unnecessary to a good life and a threat to the health of natural systems;
- economies and the global economy overall require healthy social systems;
    - current levels of material inequity are immoral, do not support human dignity, and are a threat to healthy social systems;
    - current rates of economic change, especially the drive for globalization, are outpacing our abilities to adapt and maintain the health of social systems.

which economists, ecologists, and others scholars compare and contrast different models and learn together. These issues are central to this description of the field.

While the scope and direction of ecological economics are actively discussed, there is considerable agreement among ecological economists with respect to their working assumptions. Ecological economic reasoning is not unique in its dependence on working assumptions, general beliefs about society and nature. Each research community focuses on a portion of reality and makes assumptions about larger systems, or takes a very broad view and makes assumptions about the details. No discipline understands the whole of reality, so assumptions about the relations between the parts studied and the whole are a necessity. Economist Karl Schumpeter referred to the combination of assumptions and choice of model as a scholar's preanalytic vision (Daly, 1996).

The following working assumptions (see Box 1) are broad and highly generalized in nature. Relatively few ecological economists work from all of them, yet most ecological economists acknowledge the importance of each of them and how they work together. This recognition and respect demonstrate that ecological economists see the field as a collective effort.

Threats to natural and social systems are a threat to people overall, but they are especially a threat to today's poor and to future generations. Ecological economists put social and natural systems at the center of their thinking, rather than individuals. The term social systems' encompasses all forms of economic and social organization, the legal and informal institutions that set the rules, and the knowledge and shared beliefs that allow people to understand each other. The metaphor of health helps elaborate the meaning of the mutual well-being of nature and people . Yet desirable properties of these systems remain vague. When empirical research is conducted, specific favorable qualities of social and environmental systems are adopted. Some ecological economists argue that energy use or material flows or biodiversity are sufficient indicators of biogeochemical system health. These effectively serve as their working assumptions when conducting specific analyses. With respect to social systems, justice, participation, shared-learning, human dignity, and other terms are often invoked.

Ecologists and natural scientists largely hold the assumption that the economy works within the larger biogeochemical system generally, hence the appropriateness of ecological as a modifier to economics. The concern with human communities, and how these are threatened by inequity and the speed and character of current economic change, however, are nurtured by ecological economists' broader roots in the social sciences and applied work in developing countries. By identifying environmental and social systems as central to their thinking, ecological economists are explicitly arguing that they are important, i.e., that they have value in themselves. The intertwining of *natural system* and *social system* concerns into one preanalytic vision owes much to the rich mix of scholars, from developed and developing countries, interacting through the ISEE during its first decade.

The sub-points in the working assumptions with respect to materialism, growth, and inequity are even more clearly value judgments. There are corresponding values integral to the working assumptions of mainstream economists. However, the values remain implicit, rather than explicit. By assuming, for example, that science allows us to rise above nature, and that material progress helps us all to live a better life, conventional economists are implicitly valuing these approaches. Whether one *a priori* presents people, as in nature or rising above nature, is not simply an issue of fact but a statement of a preference or goal as well. Similarly, ecological economists' moral concern with the distribution of happiness, and their strategic concern that inequity threatens the health of social systems, are difficult to separate. Such value judgments help ecological economists select and frame their research and what subsequently appears in the ecological economics literature, just as surely as historic beliefs about progress and how it helps all affect the research and literature of mainstream economists.

HISTORICAL BACKGROUND

An appreciation for the historical path of economics is essential to understanding the ways in which ecological economists have parted from that path and what they seek through exploring alternatives (Christensen, 1989; Costanza *et al.*, 1997, Chapter 2). The conclusions economists reach

are determined by the structure of their formal models, the quality of their data on the state of the economy, and very general assumptions about the relationships between economies, society, and biogeochemical reality. The particular assumptions that economists have come to share over their history differ from those acquired by ecologists, for example, and set them apart as a separate academic tribe and professional culture. Some assumptions are embedded in the ways in which economic models simplify complexity to a manageable form. Some are rooted in the social issues and liberal political philosophy of the formative years of economics in the 19th century. Additional premises were embraced as economists assumed roles as technical experts in national governments and international agencies during the 20th century to evaluate public investments, assure full employment, promote development, and, most recently, facilitate trade and international capital mobility. While there has always been diversity in formal models and assumptions among economists, particular combinations of models and assumptions have clearly dominated at different points in time, complementing the problems at hand and the political economy of power affecting economic change within nations and internationally.

Classical Economic Origins of Ecological Economics

Ecological economists have an af nity with the way many classical economists, from the late 18th through most of the 19th century, combined moral reasoning and systems thinking to describe problems and point toward solutions. Many of the most important economists in this period also knew that environmental systems and resources were central to human well-being. The following vignettes of early economists provide critical background.

Francois Quesnay (1694 1774) and the Physiocrats argued that economic activity should be governed in keeping with the laws implanted in Nature by Providence . Quesnay, an admirer of physics, named the school of economic thought he established to re ect the scienti c principles on which economic wealth was hypothesized to depend. Quesnay and his disciples developed a simple input output table of the economy, categorized by economic class, with all wealth owing from agricultural labor. A disciple of Quesnay, Anne Robert Jacques Turgot, rose to the position of comptroller general in France in 1776, began to impose physiocratic reasoning to tax policy, and was soon relieved of of ce after offending too many political interests. While the arguments of Adam Smith soon surpassed those of the physiocrats, they in uenced many 19th century economists including Karl Marx. The input output table was a precursor to modern material ow models of economies. The physiocrats were early ecological economists in the sense that the laws of natural science, to the extent they understood them, were integral to their understanding of economics.

Adam Smith (1723 1790), widely recognized as the founder of modern economics, was a moral philosopher who argued that shared moral standards develop because individuals empathize with each other. Concerned with whether individual economic decisions summed to the common good, he reasoned that if two people choose to enter into an exchange, it is because the exchange makes each of them better off. So long as the individual decisions made by parties to an exchange did not adversely affect other people, society as a whole was better off through the exchange. Appealing to Judeo-Christian images of God, Smith invoked the metaphor of the market being guided as if by an invisible hand. Smith was not simply arguing for free markets in the abstract. *Mercantilism*, a system wherein the state granted sole trading rights to particular companies, favored a few over the many. Smith argued that freer markets would be better for people overall. Thus the rst modern economist fought the socioeconomic power system of the time with ethical and economic reasoning. His plea for the market and against government intervention was in opposition to the tight relations that had developed between companies and the state, not against government *per se*. The relations between corporations and government have changed many times since mercantilism, and they are again of some concern.

Thomas Malthus (1766 1834), a clergyman turned economic philosopher, explained the prevalence of war and disease as material phenomena rather than as acts of God. He argued that human populations were capable of increasing exponentially and would do so as long as suf cient food and other essentials of life were available. He further hypothesized that people could expand their food supply only arithmetically through new technologies and expansion into new habitats. Given the geometric potential of population growth, and the arithmetic food constraint, population would periodically surpass food supply. At these times, people would ravage the land, go to war over food, and succumb to disease and starvation. Human numbers would consequently drop to sustainable levels, but the process would repeat itself again. Both Charles Darwin and Alfred Wallace acknowledged that Malthus model of population pressing against an environmental constraint was key to their formulation of the theory of natural selection. Limits to growth are also central to many ecological economic models.

David Ricardo (1772 1823) introduced a second model of how economic activity relates to the environment, not because he was concerned with environmental degradation or human survival, but rather to justify why landlords received a rent from their ownership of land. Ricardo argued that people would initially farm the land that

produced the most food for the least work. As population increased, farming would extend to less-fertile soils requiring more labor. His model shows how increasing population drives people to farm in previously undisturbed areas and how higher food prices lead to intensified effort on land already in production. His model of how humans extend and intensify land use underlies many debates over development and conservation.

John Stuart Mill (1806–1873), the son of social philosopher James Mill (1773–1836), argued that competitive markets complement individual liberty. Mill also wrote on both the immorality and the waste of subjugating women to men. He neither saw material prosperity as an end in itself nor thought continuous growth in material well-being was possible. Mill envisioned economies becoming mature and reaching a steady state, in which people would be able to enjoy the fruits of their earlier savings. The idea that economies would reach a steady state was logical. Change was common, unceasing growth was not, and relatively steady states rather than random change were perceived as natural. A century after Mill, Herman Daly, one of the founders of modern ecological economics, elaborated on the necessity and advantages of a steady-state economy (Daly, 1973).

Karl Marx (1818–1883) criticized capitalism on the grounds that it left workers at a subsistence wage while capitalists thrived. Marx, an admirer of Darwin and biological thinking, was concerned with how the introduction of fertilizer inputs produced an agricultural revolution during the 19th century that not only detrimentally transformed social relations but irreversibly disturbed ecological relations as well (Foster, 1999). He had strong progressive beliefs, arguing that capitalism was but a phase in a larger inevitable history of progress toward socialism and eventually communism. While his long-run predictions still inspire resistance movements, the logic of his critiques, his moral stance, and historical approach are an integral part of many schools of social thought to this day. The capitalist economic system was tamed during much of the 20th century, partly in response to how Marx had framed its problems. Capitalism keeps changing and has become especially virulent again at the opening of the 21st century while inequity within and between nations has increased.

Alfred Marshall (1842–1924) synthesized the work of the classical economists, retained their philosophical voice, and incorporated the findings of the mathematicians who formalized economics. Among Marshall's many theoretical contributions to economic analysis can be found frequent references to the beauty of nature, and the importance of clean air and water to a decent city life. He argued that markets, driven by the possibilities for individual gain, would not provide sufficient public goods. Lastly, he argued that while economists had drawn very successfully on the mechanical models of physics, the future of economics was in joining with biology.

Natural Science Origins of Ecological Economics

The classical economists were broadly read, aware of developments in the natural sciences, and thereby prone to address questions of natural limits. They were not, however, scientists themselves. Scientists, well aware of the rapidity of economic change during the 19th century, periodically asked how the laws being discovered in the natural sciences might affect the possibilities for economic progress (Martinez-Alier with Schlupmann, 1987). Serhii Podolinsky (1850–1891), writing on energy and economics during the 1880s, explored the implications of the efficiencies of energy use as it flows from the sun, through agriculture, on through human consumption and labor output, and hence into the broader economy. Today, agricultural energetics and the possibilities for greater dependence on renewable energy are central to ameliorating climate change. Patrick Geddes (1854–1932) argued in the 1880s that economists inappropriately blended the physical processes of economies with monetary exchanges. Much like modern ecological economists, he argued that more could be revealed if we modeled the physical and the monetary processes separately. Leopold Pfaundler (1839–1920) argued in 1902 that physical principles needed to be applied to calculate the carrying capacity of the earth to derive realistic expectations for the future. Frederick Soddy (1877–1956), a Nobel laureate in chemistry, argued in the 1920s that economists did not understand how our economies are driven by current and stored energy from the sun, that stored energy was the only real wealth, and that the conception of monetary wealth implied that economists believed people could eat their cake and have it too . A J Lotka (1880–1949) borrowed from the mathematical developments in economics to outline a theory of value based on ecological fitness (Kingsland, 1985). For reasons partly elaborated in the next section, economists did not respond to the early concerns expressed or alternatives provided by natural scientists. Today, many of these same concerns and alternatives drive the biophysical approaches of ecological economists.

The Rise of Modern Economic Culture

During the later decades of the 19th century, the market model became formalized mathematically and key concepts became much better understood. During roughly the same period, economics and the other modes of social analysis began to assert themselves as separate sciences, assuming an objective stance while actively trying to shed their ethical baggage. Economists turned increasingly inward, staying less and less in touch with advances in the natural sciences

as well as with the other social sciences, while they pretty much dropped out of philosophical discourse all together. The less economists read beyond economics, the more natural their own assumptions appeared to them. Later, during the Great Depression, economists were brought into national governments to help stabilize economies and to undertake cost-benefit analyses of alternative investments, of water projects first, and eventually almost everything. Earlier arguments about achieving the greater good were modified to justify ignoring equity issues as economists concentrated on efficiency in public policy analysis. Soon after, economists became significant players in the new mission of international development, advocating that the best way to reduce poverty was through growth. As economics turned inward academically, the shared assumptions of economists narrowed and hardened even while economists' new professional roles required that assumptions change with the problems and politics of the times.

It is important to understand that while the models of economics have become better understood through their formal development, the assumptions inherent to the models have not changed. What changed during the 20th century was how economists used their models. Early economists compared the results of their economic reasoning with that of other forms of reasoning, playing them off each other to maximize understanding. As economists assumed greater roles in public decision-making, they needed to justify that the economic way of thinking was the best way of thinking. During the last decades of the 20th century, academic economists began exploring new approaches and broadening their thinking. Professional economists, however, still have had to defend established ways and particular answers.

Environmental Economics

Environmental economics is a sub-discipline of economics. Its strongest roots are in the US where Richard T Ely, the founder of the American Economic Association at the end of the 19th century, also founded a school of land economics and utility regulation economics at the University of Wisconsin. Early environmental economists – Ely, George Wehrwein, Marion Clawson, Maurice Kelso, and Siegfried Ciriacy von Wantrup – raised fundamental questions from the 1920s into the 1960s about property, organization, environmental degradation, and resource conservation when much of the profession was engaged in mathematical refinement of perfectly functioning markets. Environmental economists in the 1950s and 1960s – Karl William Kapp, E J Mishan, John Krutilla, Allen Kneese, and Jack Knetsch – questioned growth and its effects on the environment, when their colleagues were advocating greater resource use in developed and developing countries in an economic race with the former Soviet Union. With the rise in popular environmental concern in the early 1970s followed by the energy crisis, environmental economics flourished, and the concept of market failure became central to economic understanding. The Association of Environmental and Resource Economists was founded in 1979.

Though their roots include fairly radical thinkers, environmental economists have generally extended existing economic patterns of thinking to environmental issues rather than question whether economic thinking is a part of the problem. The professional role of economists in environmental agencies has reinforced the tendency to rally behind dominant approaches rather than raise fundamental questions. The assumptions embedded in the culture of economists, and largely assumed by environmental economists, were well established before the rise of ecology as a full-fledged science in the second half of the 20th century. Economists' assumptions about nature and possibilities for the future are rooted in an earlier time when technological change seemed to only solve problems, not create new ones as fast as it solved the old. In rich countries where the sub-discipline started, environmental economists tend to advocate modest corrections to the existing development paths (*see* Environmental Economics, Volume 5).

The Rise of Modern Ecological Economics

In response to the narrowing of economic thought during the 20th century, a few scholars more open to thinking across natural and social science boundaries provided the foundations for modern ecological economics. Kenneth Boulding (1910–1993) worked with philosophers and natural scientists on a general systems theory in the 1950s, introduced the metaphor of spaceship earth to stress how economies must work within limits (Boulding, 1966) and subsequently wrote on ecodevelopment in a broad evolutionary framework (Boulding, 1978). Kneese *et al.* (1970) building on the first law of thermodynamics, constructed material balance economic models to better understand the limits of markets. Odum (1971), an ecologist, developed an energetic systems view that he applied across ecological and economic systems. Georgescu-Roegen (1906–1994) argued that economic activity needed to be understood as an entropic process (Georgescu-Roegen, 1971). Systems theorists Meadows *et al.* (1972) wrote *Limits to Growth*, convincingly arguing that unlimited growth was impossible. Daly (1973) reintroduced Mill's steady-state economy with arguments for limiting throughput of energy and materials. Entomologist turned energeticist David Pimentel documented the energy costs of alternative forms of agriculture (Pimentel, 1974).

Karl-Goran Maler of Sweden explored some of the implications of materials balance to a general equilibrium economic approach (Maler, 1974). Passet (1979) in France began to combine economic and thermodynamic thinking, while Pillet teamed up with Odum (1987) to write on energy

and economics. Many had already suggested corrections to the system of national accounts (SNA) so that, for example, expenditures correcting new environmental problems were not treated as benefits, Roefie Hueting of the Netherlands pushed the corrective process the furthest (Hueting, 1980). In 1982, about 40 economists and ecologists met in Stockholm, hosted by ecologist Ann-Mari Jansson, to explore how economics and ecology could be integrated (Jansson, 1984). At that meeting, Robert Costanza used the term ecological economics in a paper suggesting how energy analysis and economic valuation might be merged (Costanza, 1984). The term gained further prominence as the title to a book on how economists had resisted responding to challenges from natural scientists (Martinez-Alier, 1987).

While the Stockholm meeting emphasized natural constraints, ecologist William Murdoch argued that distributional issues were absolutely central to understanding economies and environments in developing countries (Murdoch, 1984). In 1987, Joan Martinez-Alier hosted a second key meeting of ecologists and economists in Barcelona. At this meeting, the nature of our understanding of complex systems and what this meant for the policy process was clearly added to the agenda of ecological economics (Norgaard, 1989; Funtowicz and Ravetz, 1990). Following discussions at Barcelona, the journal *Ecological Economics* was started by Robert Costanza and Herman Daly who also took the initiative to found the International Society for Ecological Economics (ISEE) soon after.

THE METHODS AND ISSUES OF ECOLOGICAL ECONOMICS

Ecological economists are methodologically pluralistic (Norgaard, 1989). The field includes economists using market, macro, institutional, Austrian, and Marxist forms of analysis. There are ecologists who do energetic analyses, population biology, evolutionary ecology, hierarchy theory, food web modeling, landscape ecology, and global biogeochemical modeling. Environmental historians, ecological anthropologists, development sociologists, systems theorists, and epistemologists and social philosophers, among others, also participate in ecological economics. Such a diversity of backgrounds is a strength, for each of the methods of the individual disciplines only spotlights a portion of the problem. Where models in economics and ecology share the same mathematical form, they can be combined into a broader, brighter light. Population models from ecology mesh nicely with production models from market economics. Input–output analysis is used in macro-economics and in food web analysis and some energy accounting models, hence can be readily combined. To the extent that evolutionary thinking has developed in economics, it combines comfortably with the approach of evolutionary ecology. Most of the models of ecology and economics, however, do not fit together. Thus ecological economists contend with different, and often somewhat incongruent, findings from different patterns of thinking. When the understandings gained from separate models can be aligned, confidence is gained. When separate understandings are in juxtaposition, conclusions are withheld and new questions are raised. How methods are used can best be described by looking at several particular issues ecological economists address.

Environmental Valuation

The relationship between market prices and value has long been at the center of controversy. Economists put a very specific meaning to the word *value*, defying the rich heritage of the term and constraining its meaning in discussions of the future. The early critiques of economics by natural scientists were driven by a concern that economists' understanding of value was divorced from natural limits and processes. The idea that values are inherent to nature, an idea that fuels debates among environmental ethicists today, were explored under the concept of natural value, for example, by Lotka. During the latter half of the 20th century, economists colonized this realm of value too by developing a variety of techniques for putting monetary values on environmental goods and services, the values they would have if they were traded in markets. Ecological economists use these new techniques but interpret the results with greater caution than environmental economists for three major reasons.

The first concern of ecological economists with environmental valuation comes from within economic theory itself. How much people are willing to pay (WTP) for clean air, for example, assumes that people do not already have a right to clean air. When asked how much they would be willing to accept (WTA) to give up clean air, which assumes people have the right to clean air, people give answers that are two or three times WTP, and in some studies 10 times or more. Environmental economists have generally adopted the polluter pay principle, implying that people have the rights to a healthy environment (*see* PPP (Polluter Pay Principle), Volume 4). Yet in the case of contingent valuation research, environmental economists have adopted the convention that WTP gives more appropriate answers than WTA. Ecological economists have not adopted the same convention. Rather, they see the difference between WTP and WTA as a crucial example of an underlying problem in environmental valuation.

The second concern is that market prices reflect the existing distribution of rights more generally, not simply between polluters and pollutees, but between the rich and the destitute, wealthy nations and poor, those who choose traditional ways and those who embrace the market, and present and future peoples. Existing techniques for simulating how an environmental market would work, implicitly

assume that the existing distribution of rights to resources and environmental services is the correct one. Howarth and Norgaard (1995) built an overlapping generations model of a hypothetical economy and showed that with all markets working perfectly, whether the economy was running at all for future generations depended on their having rights. With different assignments of rights across generations, resources have different prices over time. And when non-market environmental services were included in the model, environmental services have different values depending on the rights of future generations. Ironically, a motivating factor for doing environmental valuation has been to justify changing the law so that a wilderness area or an endangered species is saved for future generations. Yet neoclassical economics itself indicates that economic reasoning depends on the rights of future generations in the first place. So, there is a major problem of circularity in standard environmental economic reasoning.

The only way out of this circularity is to accept that questions about the distribution of rights must be addressed through some method of moral reasoning beyond the simple individual utility calculus behind economic reasoning. While such complications have long been recognized by utilitarian philosophers and economic theorists, acknowledging that economic reasoning alone does not result in unique answers, with respect to the public good, defeats the efforts of economists to provide simple answers to policy questions. Practicing economists, and many academics today as well, will respond that questions about the distribution of rights need to be addressed separately by others in other arenas, and that economics is just one input to the collective decision-making process. Yet the appropriate response within the economic framework would be to present policy makers with analyses indicating how different assignments of rights would affect people and how economic and non-economic activity would unfold over time. This would entail a deeper approach to economic analysis, more work for economists, and a new style of interaction with policy makers. Ecological economists have begun to take on this challenge.

Third, in the economic model, individuals have predetermined preferences and the problem of valuation is one of aggregating them to a collective preference. Individuals, however, are not born with preferences. They acquire them interacting in society and through advertising and other commercially funded media. Acknowledging that individual preferences are socially constructed opens up values analysis to the processes of their construction, how they have changed over time, which interests have influenced the changes, and whose ends are being served. It is well known that people respond differently as individuals than when as members of a group. This can be due to the social pressure of being within a group. It can also be due to the fact that many things, such as clean air and biological diversity, are very difficult to obtain acting as an individual, and so individuals, when choosing between alternatives, do not think about these things as options.

Ecological economists see individuals and groups as being able to draw on diverse multiple types of values and ethics depending on the context. Individuals have values and ethics rooted in their religion, sometimes more than one. They have values and ethics rooted in their particular cultural histories. And individuals and groups learn from their particular experiences and thereby develop values and ethics. Different values and ethical criteria are called forth depending on the setting, whether one is acting as an individual, a member of a family, within a profession, as a church member, as a citizen, etc. Because these categories are not exclusive and one is accountable in multiple, and not always foreseen, settings, weighing alternatives, individually and collectively, is considerably more difficult than a simple utilitarian calculus. It is also much more interesting (O'Connor, 2000).

In opposition to the western fact – value dichotomy, ecological economists are a little more prone to see facts and values as interlocked. There were no predefined preferences for biodiversity for example, before ecologists began to study the importance of biodiversity, and new technologies allowed us to better understand genetics in the last quarter of the 20th century. To be sure, we now recognize particular species and genetic traits as being important, as we have come to realize how something of prior value, say a medicinal drug, is obtained and must be protected. But such particulars are not biodiversity, though efforts to value biodiversity have certainly been attempted through aggregating particulars. Rather, we now value biodiversity *per se* even though there are multiple definitions of the term and we only know the number of species within an order of magnitude. In effect, biodiversity is a term like health, something that carries with it connotations of value as vague as the term itself, but very important to people nonetheless.

Ecological economists are interested in how social systems produce and reproduce some types of values and not others at different times. They are interested in how new mechanisms for making collective choice can be established that take advantage of expert advice, economic calculations, and group learning. Values juries seem like an interesting possibility. When ecological economists do an analysis that aggregates values in a single numeraire, they explore its strengths and weaknesses from the perspective of values having multiple realms.

Correcting the System of National Accounts

The primary creator of the SNA, Simon Kuznets, warned that gross domestic product (GDP) simply measures market and government activity, not well-being. Karl William

Kapp, an early ecological economist, documented how the accounts failed to consider natural resources appropriately as well as household labor (Kapp, 1950). Various economists, in response to the environmental concerns of the early 1970s, looked into the shortcomings of the SNA. Ecological economists, including Herman Daly, Robert Goodland, Roofie Hueting, Richard Norgaard, and Henry Peskin, participated during the 1980s in efforts hosted by the United Nations Environment Programme and the World Bank to correct the SNA. The goal was to treat the depletion of resource stocks like the depreciation of capital and to treat expenditures to correct expanding environmental problems as intermediate rather than final products. These were seen as simply better accounting practices. Some also hoped, however, that sufficient corrections could be made so that GDP, or some new aggregate measure, not only made a serious effort to measure economic well-being but also to account for whether that well-being could be sustained.

Working with Herman Daly, Clifford Cobb devised and undertook the empirical work to derive an *Index of Sustainable Economic Well-Being* (ISEW) (Daly and Cobb, 1989). The ISEW shows sustainable well-being increasing until around 1970, and then declining since. The ISEW, in different stages of evolution, has been calculated for many countries by non-governmental organizations (NGOs) with similar results. The ISEW has evolved further in the hands of *Rede ning Progress*, a US NGO, into the *Genuine Progress Indicator* (Cobb *et al.*, 1999). Even though rates of growth increased dramatically during the 1990s, the GPI declined because of increasing inequality, increased defensive environmental expenditures, and growth that has been at the expense of future generations (*see* ISEW (Index of Sustainable Economic Welfare) and GPI (Genuine Progress Indicator), Volume 5).

Since the 1980s, governments around the world have begun to incorporate some of the suggestions to correct their SNA. They have consistently taken the approach, however, of developing satellite accounts of environmental expenditures and stock resource depletion, and not used this information to adjust GDP or devise a new aggregate indicator. The rationale for developing but not incorporating environmental and resource accounts has been explicated by a study of the US National Research Council (Nordhaus and Kokkelenberg, 1999).

Whether one is devising a new aggregate indicator or simply establishing environmental and resource satellite accounts in monetary units, one must determine unique, defensible values for non-market goods and services. Since the 1980s, however, ecological economists have enriched their ranks and acquired a more complex understanding of values. This development makes it increasingly dif cult for ecological economists to recommend and defend any particular formal method for deriving non-market environmental values for standardized accounting purposes. Accounting for resource depletion using values derived from current resource prices, for example, may grossly under-represent the value of that depletion, for new extraction technologies may be keeping current prices low while their value to future generations remains high. There is also a concern that no one indicator will ever be adequate. Herman Daly is fond of saying that looking at GDP to plan for the future is like driving forward looking into the rearview mirror. While looking out the windshield is a major improvement, those working on indicators of human well-being, environmental well-being, and sustainability are increasingly talking about a dashboard of indicators. Nevertheless, most ecological economists support environmental accounting as an improvement over not accounting for the environment. Ecological economists also hope that the process of deriving and disseminating environmental accounting information will help lead people to ask deeper questions.

Biophysical-Economic System Analysis

The efforts to link the natural sciences with economics are numerous, with none being dominant. At best, a cursory summary of the work of ecological economists can be provided. First, as methodological pluralists, ecological economists rely on the natural sciences in order to understand the limits of particular economic models and assumptions, and they accept the ndings of biophysical analyses on their own terms, as additional information of equal importance as that stemming from economic analysis. Second, ecological economists have linked, and in some cases integrated ecological and economic models. Third, the concept of joint production from economics has been developed as a link between economics and the natural sciences. Fourth, ecological economists have extended models from the natural sciences to economics, dispensing with traditional models of economics altogether. Each of these needs elaboration.

Ecological economists often compare the differences in the insights derived from natural science and economics. Gowdy (1994), for example, has explored the concept of coevolution in biology, how it relates to cultural ecology in anthropology, restated institutional economics in coevolutionary terms, and compared all of this with conventional market analyses. Malte Faber and others have further developed the ideas of Nicholas Georgescu-Roegen, arguing that, as we rely less and less on current solar energy and more and more on fossil hydrocarbon and other mined resources, economic activity needs to be understood as moving toward a closed system and subject to the second law of thermodynamics (Faber *et al.*, 1996). This means that we need to understand economic activity as an entropic process, as taking high quality energy and materials and reducing them to waste heat and dispersed minerals. Looking at new technology from this perspective, we see that it allows economic

activity to accelerate, for entropy to increase faster, leaving less for the future, not more. Thus, to the extent that we rely on stock resources, especially of energy, progress is not possible, indeed even sustainability is not possible. The alternative, of course, is to return to relying on current solar energy, in part by working with natural systems. This, however, raises further issues.

Humans are co-opting approximately 40% of the primary energy captured by terrestrial ecosystems (Vitousek *et al.*, 1986). Ecological economists use this study as an indication of how human activity has transformed the environment, and as an indicator of the limits to further transformation. For Herman Daly and other ecological economists, the analysis of Vitousek stresses the urgency of moving to a steady state while there is still some margin left (Daly, 1996).

Wackernagel and Rees (1996) have used biophysical analysis to calculate the *ecological footprint* of a population, the area of productive land and water needed to produce the resources it consumes and assimilate the wastes it produces. Ecological-footprints range from approximately 0.5 hectares per person for people in very poor countries to 10 or more hectares for average Americans; the rich use even more (*see* **Ecological Footprint**, Volume 3). Biophysical analyses provide critical insight into our use of stock resources (Cleveland and Kaufman, 1991), into carrying capacity, and into the difficulties of moving toward life-styles consistent with carrying capacity (Folke, 1991; Kaberger, 1991; Jannson, 1991). While biophysical indicators create considerable controversy within ecological economics when their supporters argue that they are suitable for making policy directly, they contribute to how ecological economists understand the relationships between people and nature.

Second, Volterra's logistic growth curve has long been incorporated in the economics of forests and fisheries. Going beyond this, but still building on the heuristic models of population biology, the field of bioeconomics arose with the mathematical models of Colin Clark (Clark, 1976; Conrad and Clark, 1987). Ecological economists have pushed further in this direction. The relationship of biological concepts to ecological economics have been explored: ecological stability (Common and Perrings, 1992); ecological resilience (Brown and Roughgarden, 1995), and biological diversity (Norgaard, 1987; Perrings *et al.*, 1995). Empirical research has also linked ecological systems and economic choices (Costanza *et al.*, 1989).

Third, some ecological economists argue that the idea of joint production from economics provides an adequate bridge to the natural sciences. A petroleum refinery, for example, produces a range of products from jet fuel to tar, jointly in the sense that it is difficult to get one without the other. All production processes, however, jointly produce good things and bad things. Economists have simplified their models by only looking at the good things produced rather than the total set of desired and undesired outputs that show consistency with the first and second laws of thermodynamics. While economists have downplayed joint production as a relatively rare situation, from an ecological economic perspective, the concept of joint production provides a critical connection between economics and understanding from the natural sciences (Baumgartner *et al.*, 2000).

Fourth, a few ecological economists have dispensed with economic models altogether and used methods rooted in the natural sciences to understand the human predicament. For example, Howard Odum (1996) has argued that the concept of emergy , defined as the energy used up in an ecological or economic process, can be used to trace costs through ecological and economic systems, providing better measures of value and wealth. Odum argues that emergy analyses provide a scientific basis for choosing between alternative technologies and development projects (*see* **Emergy**, Volume 5). On the other hand, Richard Norgaard pursued a coevolutionary explanation of change to a conclusion that substantially changes how we treat expert knowledge. He argued that social and environmental change can be understood as a coevolutionary process between value, knowledge, organizational, technological, and environmental systems. Characteristics within each system select upon the fitness of characteristics in the other systems such that they coevolve together, reflecting each other, and becoming tightly interlocked. But change does occur through biological mutations, cultural innovations, and introductions from other ecosystems and cultures (Norgaard, 1994). Thus, collective action can best be based on a process of shared knowledge between scientists, those with traditional and experiential knowledge, and those who will actually be implementing the change.

THE FUTURE OF ECOLOGICAL ECONOMICS AND RELATED ALTERNATIVES

The future of ecological economics depends on three broad issues. The first is whether ecological economics will evolve into a new overarching paradigm or whether it will remain an umbrella under which multiple, contradictory analyses are undertaken. This has important ramifications with respect to how ecological economics is put into practice. The second issue is whether ecological economics will become a field that is embraced by scholars in the developing world as it has historically developed around scholars in Europe and North America. The third issue is how the scope of ecological economics will be affected by the development of other transdisciplinary fields. Of particular importance are the developments in agroecology, conservation biology, ecological engineering, and industrial ecology starting from the natural sciences, and the study of

the commons and political ecology starting from the social sciences. At the same time, the fields of economics and ecology themselves continue to evolve and will also thereby affect the future of ecological economics.

New Overarching Paradigm or Continued Methodological Pluralism?

Among ecological economists, there is already considerable agreement on underlying assumptions and on the need to learn across models and disciplinary cultures. This agreement itself indicates ecological economics is a new overarching process, if not a paradigm. Many ecological economists from its beginnings, however, have pleaded for greater unity (Daly, 1984; Proops, 1989). To them, an overarching model, or perhaps a small set of broad models, is needed to understand, not simply describe, the big picture and to guide practitioners to appropriate particular models. Ecological economists need to establish a new language. Simply incorporating the languages of multiple disciplines, with the same words having different historical meanings, makes it difficult to communicate to the public and policy makers. Taking ecological economics to public and policy arenas has, thus far, entailed hiding its richness and concentrating on correcting the SNA or making arguments for reduced material and energy flows. The US Environmental Protection Agency made a small effort to understand how taking a broader approach to valuation might work (Bingham *et al.*, 1995), but has not implemented any of the recommendations. Conventional economic thinking is well entrenched in political discourse and agency decision-making in part because it is simple and consistent. It is difficult to imagine how a field as eclectic as ecological economics can have an impact without having comparable coherence.

On the other hand, continuing the methodological pluralism of ecological economics is not a default position for its advocates. Rather, the pluralists have compelling arguments too. First, many scholars have sought unity within the natural sciences and within the social sciences without success, so the chances of unity across them are slim indeed. Methodological pluralism is a reality. At least for the foreseeable future, ecological economists should not pin their hopes on accomplishing something so difficult as unifying either the natural or the social sciences, let alone the combination of the two. Second, agreeing on less than a truly overarching model would entail reducing the scope of inquiry of ecological economics. This would make the field more vulnerable to mistakes and surprise in the future. Third, reducing ecological economics so that it fits into the existing policy process is accepting defeat from the beginning. The existing political discourse is dominated from the top by those who have money. It needs reinvigorating with a new paradigm that is more democratic. Ecological economists, as pluralists, are more open to discussing a multiplicity of values and incorporating the voices of those with traditional and experiential knowledge. With respect to the policy process, the existing agencies are set up to act on advice from experts speaking separately. Inter-agency task forces, science juries, and other interactive consensus-building innovations are opening up this process, and it is through these and further evolutions (Irwin, 1995; Stern and Fineberg, 1996), perhaps to full discursive democracy (Dryzak, 1990; Fishkin, 1991), that the richness of ecological economic understanding can be effective. Fourth, different methods inherently stress different values. By focusing on different things, each model says, this is important , and, by implication, that is not . The multiple languages, especially of the social sciences, also reproduce and transmit values from different historical and cultural settings. In this sense, the plea for cohesion in models and language is a plea for historical denial and cultural extinction.

Ecological Economics as a Global Enterprise

Ecological economics is becoming the preferred base for economists and other scholars working to implement sustainable development in economically poor countries. Scientists trained in western ways of thinking must overcome strong cultural barriers as they work in poor rural communities. From this perspective, disciplinary boundaries are but a minor nuisance. And implementing sustainable rural development clearly requires input from multiple disciplines. Scholars from the economically poorer countries are becoming stronger and more assertive as their numbers increase and as the economic gap between rich and many, though certainly not all, poor countries increases. The shared vision of development, with each nation developing a full complement of economic sectors and public services, has collapsed to a northern vision of globalization. North–South tensions over the amelioration of climate change and biodiversity loss have arisen within the dominant conceptual and institutional frameworks. Ecological economics, with its emphasis on equity and respect for the diversity of ways of knowing, has a tremendous opportunity. Ecological economics could become a global network of scholars learning together, building a global vision for the future that respects diversity while demonstrating how that vision could be achieved.

Other Alternatives to Economics

In addition to the work of ecological economists, there are other efforts to affect how a narrow pattern of reasoning from economics has dominated modern policy and politics. Like ecological economics, most of the other alternatives also span multiple disciplines. Social scientists have joined in the study of *common property management*

regimes. Economists and sociologists have joined to understand *socio-economic systems* together. Political economy, the study of power that has evolved across the social sciences since Marx, is now complemented by the emerging field of *political ecology*. There are similar efforts centered in the natural sciences that are reaching across to the social sciences. For example, biologists concerned with the conservation of biological diversity are anxious to work with economists. Academics and practitioners are organizing around the ideas of *ecosystem health*, *industrial ecology*, and *ecological engineering*. Many ecological economists also participate in these other interdisciplinary efforts. And like ecological economics, most of these efforts are questioning the conventional assumptions of how science relates to the policy process. While it is clear that ecological economics is clearly focused on the interplay between ecological and economic understanding, all of the emerging interdisciplinary efforts ask related questions to some extent. Thus the future of ecological economics depends on how numerous parallel and overlapping interdisciplinary efforts evolve in the context of each other.

Environmental Politics

ROBERT PAEHLKE

Trent University, Peterborough, Canada

Many analysts date contemporary environmental politics, especially in North America, from the 1992 publication Silent Spring, or from the first Earth Day (April 22, 1970). The historic roots of environmental politics of course run deeper, but it is first important to distinguish environmental politics from all other forms and aspects of politics. One way to do this is to draw a distinction between environmental politics and distributive (also called redistributive) politics. Distributive politics is about the involvement of government in the distribution and redistribution of economic and social benefits and disbenefits among the individuals, groups, interests, and regions of any given polity. It is also about the social and economic management inherent in the maximization of the total economic pie to be distributed. Environmental politics, in contrast, primarily focuses on the unintended negative consequences of this latter pursuit, on the protection of human health, on the well-being of other species and on the long-term future of human generations, or on such other non-monetary values as wilderness.

Given this focus, which favors not so much capital or labor, or rich or poor, environmentalism is sometimes said to be neither left, nor right (Paehlke, 1989). There is much truth to this claim despite the fact that many on the political right see environmentalism as a variant of the left, notwithstanding that are environmentalisms of the left, right and center. Left environmentalism looks to regulate corporate polluters and to democratize within the public sphere significant segments of economic decision making. Right environmentalism rather favors what are called market-based policy tools, worries a great deal about population (though it may simultaneously reject choice regarding abortion), and believes that the market is the best means of protecting the environment (through green products and other means of feedback to private economic decisions). Centrist environmentalism is inclined to some mix of these polar perspectives.

Environmental politics has, essentially, placed three distinct value sets into competition with other societal objectives such as profit maximization or short-term economic growth. The three value sets are: (1) wilderness, biodiversity, habitat and nature; (2) pollution reduction and the protection of human health from environmental hazards; and (3) sustainability (Paehlke, 1997). Each of these has a deep history preceding the beginnings of contemporary environmental politics; those beginnings in effect identify when environmental politics became more integrated and rose to a significant place within the wider political agenda-setting process. After 1960 environmental issues came to have real resonance for significant numbers of people, were regularly reported in the media, and soon thereafter led to a wide array of relevant legislative initiatives and administrative points of contact. Long before that point, however, many of these values were advanced by an earlier conservation movement or put forward by thoughtful individuals.

Arguably, broad-based environmental politics only became possible when and where a certain level of material prosperity had been achieved. As Samuel Hays (1987), the US environmental historian, noted:

Evolving environmental values were closely associated with rising standards of living and education.… But with rising incomes something beyond necessities and conveniences now lay within the reach of many; they may be called amenities.… Environmental quality was an integral part of this new search for a higher standard of living.

(Hays, 1987)

Thus, from the 1950s onwards the amenities associated with prosperity came more and more to include outdoor recreation, air and water quality, and the protection of the broader-than-economic well-being of future generations.

ENVIRONMENTAL VALUES: THE BASIS OF ENVIRONMENTAL POLITICS

Concern for the rst of the three dimensions of environmental values, the preservation of wilderness and the conservation of nature, has deep roots, especially in North America, the US in particular. Conservation moved from the realm of ideas into the realm of environmental politics and policy in the late 19th century with the campaigns for and the creation of national parks, in Yellowstone (1872) and Yosemite National Parks in the US and Banff National Park in Canada (1885). Indirectly related to those events were the important writings of George Perkins Marsh, John James Audubon, and, perhaps especially, Henry David Thoreau. John Muir, a founder of the Sierra Club in 1892, contributed enormously to the development of the idea of wilderness and to the campaign to preserve it.

Marsh (1801 1882), a Vermont lawyer and politician who traveled extensively, was one of the rst to systematically study the many ways in which humans have disrupted nature (*see* **Marsh, George Perkins**, Volume 3). Late in life, he produced a remarkable book that in many ways foreshadowed by a century the modern environmental movement. The book, (Marsh, 1965) *Man and Nature* in 1864, argued that humans had gained great power to alter nature and were doing so to the detriment of both nature and themselves. Marsh cited and documented the effects of deforestation, erosion, loss of biodiversity (he did not, of course, use that modern word), altered water regimes, and general loss of biological productivity. He cited examples from his native Vermont, from Europe and Turkey (where he had served as Ambassador) and argued that the destruction of wilderness in the pursuit of human gain was imposing too many costs. Parallel, but less documented, expressions of concern were advanced at the time by artist John James Audubon (1785 1851) and Henry David Thoreau (1817 1862).

These early expressions of concern were heard, but the time was not ripe for environmental politics in practice which could lead to effective public action. At the time most North Americans were doing all they could to survive through agricultural pursuits which in turn required the clearing of forests, not their preservation. The writings of these authors are revered today as profound early insights, providing historic depth and richness to the contemporary environmental movement. The works of all three, from Audubon s paintings of birds to Thoreau s literary masterpiece *Walden*, served to inspire those who followed.

Among those inspired by Thoreau s life and writings was John Muir (1838 1914). Muir took things further politically than did Thoreau. Also a gifted writer about nature, the Scottish born Muir, having explored vast tracts of America, including Florida and California on foot, published widely-read essays in the leading magazines of the day. In the 1880s Muir successfully campaigned for the establishment of Yosemite National Park in California. Muir s Sierra Club remains today one of the largest and most in uential of North American environmental organizations. Earth Day is celebrated on a date near to John Muir s birthday. In the early part of the century, conservationist in uence in the US reached even into the White House, especially during the presidency of Theodore Roosevelt.

Leading European gures in the early history of environmental thought include Gilbert White of Selbourne, England who provided, in the mid-18th century, one of the earliest detailed accounts of the complex associations and interactions within nature, a precursor to the modern science of ecology. Notable in the 19th century, as precursors of conservationism and as promoters of a poetic and aesthetic appreciation of nature, were Wordsworth, Ruskin, and Morris. This sensibility informed the formation of Great Britain s National Trust and the efforts to protect both the built and the natural environment. Equally important to the eventual development of environmental politics were political philosophers including John Stuart Mill, who was the rst to discuss steady state economics and Edmond Burke, whose organic vision of community and tradition even today lends support to political thinking regarding the environment. Finally here one must mention Svante Arrhenius, the Swedish chemist, who hypothesized in 1896 that the carbon dioxide produced by burning coal could ultimately contribute to warming the climate of the planet.

The growth in human numbers and the spreading and sprawling of human settlement associated with industrialization and motorized transportation throughout the 19th and 20th centuries continuously and dramatically reduced the quality of habitat for wild plant and animals. Humans came to occupy and utilize a very high proportion of what was once wild space. Much of North America (excluding Canada s North), and virtually all of Europe and the rest of the world, is now a human-controlled landscape. Telecommuting and other new communications-based technologies may accelerate the dispersion of human habitation. As this process has advanced through the centuries, many have come to realize that only conscious conservation and careful land use policies can keep any signi cant portion of the planet open to wild non-human species and spaces. Two additional developments in the idea of conservation came with Aldo Leopold s land ethic and, later, the widely in uential ideas of deep ecology, especially the thinking of the Norwegian philosopher Arne Naess.

Leopold, an early forestry graduate from Yale University, worked as a forester and wildlife manager. As he grew older he doubted more and more the utilitarian conservation philosophy which he had been taught and had practiced. Leopold developed a philosophy rooted in the science of ecology, in the interconnections between animals, plants, water and soil; he envisioned humankind as an ordinary member, rather than a conqueror, of the community of the

land. Naess, and other deep ecologists writing in the 1970s, continued the development of an ecologically based ethic. They distinguished between a human-centered (anthropocentric) approach to human-nature relationships from an eco-centric (deep ecology) approach. Essentially, the latter views ethical issues from non-human viewpoints and has formed the basis for the animal rights movement, the radical defense of wilderness and the rejection of those forms of conservation based in resourcism wherein all nature is valued solely in terms of the needs of humans (*see* Leopold, Aldo, Volume 5).

The ideas underlying the conservation movement prior to the 1960s were primarily focused on the conservation and preservation of resources, wilderness and nature's diversity. However, in the early days of the environmental movement the primary emphasis within environmental politics shifted to pollution and the effects of pollution and toxic chemicals on human health. These new concerns had their own history, but prior to the 1960s did not often capture the public imagination or a place on the wider political agenda. In contrast, in the 1960s, many of what had come to be called environmentalists saw traditional conservation and wildlife protection organizations as too conservative, as not sufficiently aware of the more important dimensions of the environmental crisis. The environmental movement looked more to urban concerns and did thereby reach, politically, a broader segment of the by then urbanized population than had the conservation movement. In effect, only some people care about nature and other species, but everyone can be aroused by concern with the air humans breathe, the food we eat, and the water we drink.

Historically, public, medical and political concern regarding air or water pollution can be traced to the ancient Persians and Romans and is even mentioned obliquely in the Christian Bible at Deuteronomy 23: 12–13. In 1273 restrictions were placed on coal burning in the city of London and in 1661 the Englishman John Evelyn submitted a tract entitled *Fumifugium* regarding air quality in that city to Charles II. In 1713 the Italian physician Bernardino Ramazzini published a compendium of diseases related to toxic exposures and other hazards in the workplace and in 1775 Percivall Pott discovered an epidemiological link between coal tar exposure in British chimney sweeps and a higher incidence of scrotal cancer. In the 19th century there was limited legislative action regarding pollution in both Great Britain and the US (in mid-19th century in Britain, in 1876 in St. Louis and in 1881 in Chicago). Smokestacks were required, though pollution abatement as we now know it was not an available option. At the same time some water pollution in rivers was the result of the removal of open sewage from public streets and lanes.

Only in the 20th century did pollution abatement progress significantly, but that progress was in part the result of an even greater need. Human population swelled, pesticides were more widely utilized, industrial capacity swelled enormously, and the array of toxic industrial chemicals broadened (especially with the massive post-WWII expansion of petroleum-based chemical industries). The environmental politics of pollution first took hold with large numbers of people in the 1920s with regard to the risk of acute poisoning from pesticides such as lead arsenate and other arsenic-based agricultural chemicals. These concerns ran high in Europe and in the US and grew larger with the publication in the 1930s of two sensational best-sellers: *One Hundred Million Guinea Pigs* and *American Chamber of Horrors*. As a result, residues of arsenic-based insecticides on foods were regulated in the US in 1932, but those standards of protection were reduced later in the decade as overt public fears subsided. Soon afterwards these toxic pesticides were replaced with 1,1,1-trichloro-2,2-*bis*-(p-chlorophenyl)ethane (DDT), hailed at first as a miracle chemical.

It was DDT and related pesticides that played a significant role two decades later in the development of the contemporary environmental movement. With DDT and related compounds, the concern was less with direct toxicity of residues for human health, but rather with bioaccumulation within food chains and the resultant ecological disruptions. Many organic chemicals are persistent in the environment and accumulate in the bodies of virtually all animal life, in ever higher concentrations the higher one goes in the food chain (from insects to small fish to larger fish to eagles, for example). As Rachel Carson pointed out in *Silent Spring* anti-mosquito use of 1,1-dichloro-2,2-*bis*-(p-chlorophenyl)ethane (DDD) at 0.02 parts per million (ppm) resulted in lake plankton with 5 ppm, small fish with 40–300 ppm, and large fish with up to 2500 ppm. At 1600 ppm the fish-eating birds around the lake died out, at a time when the chemical was no longer detectable, even in trace amounts, in the lake. Contemporary environmental politics has been very much about the sciences of toxicology, epidemiology and ecology.

What makes Rachel Carson a founding figure in environmental politics is her ability to integrate diverse small scientific findings and to array that data and present it to a wider public of non-experts in a careful and forceful way. Carson was not afraid to draw conclusions and to do so in a very public way. Despite massive attacks on her science and her credibility by industry representatives, her views held up and a wide range of policy initiatives ensued (and a new dimension of politics was born) (*see* Carson, Rachel Louise, Volume 5). Concern with pollution in the public mind was also fueled by two acute air pollution disasters (in Donora, Pennsylvania in 1948 and in London, England in 1952), and perhaps as well by general fears related to then, widespread above ground nuclear weapons testing. Environmental politics arose out of these factors and soon eclipsed conservation concerns in terms of public attention.

The third strand of environmental ideas and values, sustainability concerns, has also had a long history. The focus on sustainability values goes back at least to the writings of Thomas Robert Malthus (1766–1834). Malthus was a moralist who concluded that human population would inevitably outstrip humankind's ability to produce sufficient food; as he saw it, the former increased geometrically (or exponentially), while the latter increased arithmetically (or incrementally). Malthus was the ultimate naysayer to the boundless optimism in the liberal intellectual circles of the time wherein it was imagined that progress and increasing bounty were natural characteristics of the human condition. Where liberals believed in the perfectibility of humans, education, science and democracy, Malthus was a pessimist who only hoped that human depravity and overpopulation could be checked sufficiently to avoid the worst of resource shortfalls and misery. Misery for the poor, however, was seen as one of three necessary checks on excessive human population growth; Malthus opposed the Poor Laws of the time as overly generous.

Few contemporary sustainability advocates are eager to embrace Malthus as an intellectual heir, neither are they enthusiastic about W Stanley-Jevons, who published *The Coal Question* in 1865. This book presented a calculation of the rise in coal consumption in Great Britain between 1854 and 1864 (at 3.5% annually) and concluded, given known domestic reserves, that the burgeoning nascent industrial society was not likely to be long-lived. In his words:

> we cannot long maintain our present rate of increase of consumption ••• we can never advance to the higher amounts of consumption supposed ••• the check on our progress must become perceptible within a century ••• the cost of fuel must rise, perhaps within a lifetime, to a rate injurious to our commercial and manufacturing supremacy; and the conclusion is inevitable, that our present happy condition is a thing of limited duration.
>
> (Jevons, 1965, 271)

Jevons did not allow for the rise of an industrial economy based on other fossil fuels, traded globally and extracted even from under the sea.

As off the mark as both Malthus and Jevons were, they were right that resources are available in only finite amounts, that there is some limit to the human population that can be supported by nature's capacities, and that resource limits can restrain economic development and social well-being. Where they were wrong was in assuming that, inevitably, limiting outcomes would follow from shortages in one particular resource at one given level of technological development. They were also too early to appreciate the ecological and human health implications associated with continuous and simultaneous growth in human population, resource extraction and industrial production. It is not so much that the human population and total economic output cannot possibly grow, but that they can and that the price paid is not always worthwhile it in net terms; and without technological selectivity and careful planning. That is a contemporary view of sustainability, though there is far from unanimity, even among environmentalists, regarding such matters.

Two other, more modern, precursors of the sustainability debate are the American conservationists Fairfield Osborn and Samuel Ordway. Osborn spoke of the goal of humanitarianism being, not the quantity but the quality of living (Osborn, 1953, 226). Population restraint and resource conservation in the name of a higher quality of life were central objectives for both Osborn and Ordway. Ordway (1953, 31), feared that without careful use:

> ••• basic resources will come into such short supply that rising costs will make their use in additional production unprofitable, industrial production will cease, and we shall have reached the limit of growth. If this limit is reached unexpectedly, irreparable injury will have been done to the social order.

The solution: restraint and perhaps redirection of human material wants. In Osborn's words, we ••• must temper (our) demands and use and conserve the natural living resources of the earth (Osborn, 1948, 201). In Ordway's Our needs can be supplied if our wants are bridled ••• The false ideology which worships unlimited expansion must go (Ordway, 1953, 39).

These views, penned and not widely influential in the hyperexpansionist 1950s, when each year's new automobiles were larger and less fuel efficient, would have had very great resonance within the environmentalist politics of the 1970s. Only then did these three strands of environmental thought, ecology, health, and sustainability, come together in an integrated way under a banner of environmental politics. Only perhaps from the late 1960s were these values widely important for more than fleeting periods of time. Only after Earth Day (1970) could one speak of a significant environmental movement and environmental politics as a important force within the whole of society in a number of nations.

SINCE EARTH DAY: HIGHLIGHTS OF RECENT ENVIRONMENTAL POLITICS

Following the publication of *Silent Spring*, public concern with pesticides, pollution and environmental protection continued to grow though these concerns were all but overwhelmed at the time by concern regarding civil rights (especially in the US) and opposition to the war in Vietnam (throughout the world). However, by the late 1960s concerns such as the accelerating growth of the human population worldwide and incidents such as the massive oil release from the Torrey Canyon off England in 1967 and the Santa Barbara offshore oil blowout in 1969, opposition to airport noise and the proposed Concorde and supersonic transport (SST) jetliners, threats to whale populations

from heavy hunting with advancing technologies, concerns regarding nuclear power and nuclear testing, combined with a number of conservation issues, especially the proposed construction of a ski resort in Mineral King Canyon (in California) by the Disney Corporation and the proposed construction of a dam at Lake Pedder in the Australian state of Tasmania, accelerated the development of environmental politics. One important outcome of this new concern was the passage in 1969 of the pioneering piece of legislation in the US, the National Environmental Policy Act (NEPA) which introduced environmental impact assessment, a procedure soon widely adopted.

Another result of, and a further stimulus to, the growing salience of environmental politics was the first Earth Day (April 22, 1970). US Senator Gaylord Nelson, a Democrat from Wisconsin, proposed the application of the teach-in techniques of the peace movement to rising environmental concerns. The results were remarkable. *Time Magazine* estimated that 20 million Americans took part, others that Earth Day events involved individuals in 1500 universities and 10 000 schools. There were simultaneous demonstrations in major cities and new organizations and publications arose in the year leading up to Earth Day and the year following. New, still significant, activist organizations included Pollution Probe in Canada, Environmental Action in Washington, DC, and the Natural Resources Defense Council in Washington, DC. Also newly created within this two-year period were the (US) Environmental Protection Agency and Environment Canada. The early 1970s witnessed an array of strong new legislation within many jurisdictions.

Following on NEPA and Earth Day, the US passed a new Clean Air Act in 1970 and a Clean Water Act in 1972. The Safe Drinking Water Act was passed in 1974 and the Resource Conservation and Recovery Act in 1976. Canada passed its Clean Water Act and Fisheries Act amendments in 1970; its Clean Air Act in 1971, Ocean Dumping Control Act in 1975 and Environmental Contaminants Act in 1976. The European Council adopted its First Action Program (on the environment) in 1973 and issued directives on quality objectives for drinking water in 1975 and water quality in 1976. Generally, Europe was slower off the mark than North America in this period, but pioneering efforts such as the establishment of the publication *The Ecologist* and its 1972 publication of *Blueprint for Survival* are particularly notable. In Australia, following some initiatives at the state level, in 1974 the Whitlam Labor government passed an Environmental Protection Act requiring advance consideration of the potential environmental consequences of proposed resource initiatives.

Whereas pollution was the focus of environmental politics on Earth Day, and in the ensuing period, sustainability issues also came to the fore, beginning in 1972 with the United Nations (UN) Stockholm Conference on the Human Environment. The conference emphasized a wide range of issues related to environment and development, as well as trade in endangered species, the protection of cultural and natural heritage and the prevention of marine pollution. Stockholm was crucial to the early establishment of environmental politics on the global stage. That year also saw the publication of the Club of Rome sponsored *Limits to Growth* (Meadows *et al.*, 1972), which gripped public attention, in part because it was based on the then-new notion of a computer simulation. This best-selling book polarized public opinion between those who saw a need for radical reform of industrial society to avoid resource exhaustion, pollution and human overpopulation and those who defended the *status quo*. The long-term projections from trends put forward in the study were widely attacked, and doubtless flawed in the details and in a number of the assumptions made. However, those flaws were soon overrun by immediate real world events. The Organization of Petroleum Exporting Countries (OPEC) slowed exports and radically escalated oil prices in 1973 (and again in 1979) and the world entered into the period of the energy crisis.

The energy crisis accelerated and altered the course of development of environmental politics throughout the world. Oil prices rose rapidly and the price of other energy sources and most commodities, including food, rose with them. Sustainability attained an intensity of public concern easily equal to that of pollution and the protection of nature. As well, for the first time, large numbers of people reflected on the long-term viability of industrial society. Prior to 1973 few had, since the arrival of the age of oil, imagined a world without readily available and inexpensive energy. This new concern was particularly challenging to any who doubted the viability, or desirability, of nuclear energy. The energy crisis stimulated sales of fuel-efficient automobiles, energy efficient appliances and home insulation, but it did not straightforwardly advance support for all aspects of environmental politics.

Through much of the 1970s, environmental concern with the dangers associated with oil tankers, pipelines and offshore oil exploration, opposition to nuclear power, and calls for the regulation of air pollution from coal seemed to some to stand in the way of energy independence and continuing prosperity. Environmentalists and OPEC alike seemed to challenge both the way of life and the economic wellbeing of wealthy individuals and societies. Environmentalists appeared to some to be saying no, or go slow, to every viable alternative to OPEC's political and economic power. However, two factors soon lessened that political tension: the notion of soft energy paths and the reality of nuclear accidents (as well as the high and rising costs of nuclear construction and the unknown cost of the long-term management of nuclear wastes).

A young physicist/environmentalist named Amory Lovins coined the concept of a *soft energy path* – an energy future that combined significant increases in

energy efficiency with the development of relatively environmentally benign, and renewable, energy sources (Lovins, 1977), solar power, wind power, geothermal energy, biomass, and small-scale hydroelectric generation. Detailed country-by-country studies were undertaken by Friends of the Earth and other environmental organizations to demonstrate the technical and economic feasibility of these combined options to both fossil fuels and nuclear power. Lovins himself was perhaps most concerned to undermine the view that nuclear electricity was a reasonable future alternative to fossil fuels; he emphasized the variety of risks associated with nuclear-generated electricity including the possible proliferation of nuclear weapons. Opposition to nuclear electricity was strong throughout the 1970s, especially in Germany, Sweden, Austria and the US, but notably not in France where Green politics had a much slower start than elsewhere in Europe and where there was also relatively wide nationalist-rooted support for a national nuclear weapons capability.

The Nuclear industry's problems accelerated following the accidents at Three Mile Island in Pennsylvania in 1979 and the far more serious mishap at Chernobyl in 1986. Nuclear energy also suffered from two other problems. Especially punishing to nuclear power were high interest rates put in place in the early 1980s to counter high inflation (resultant in turn in large part from high fossil fuel prices). Construction of nuclear power plants is slow and thus high interest rates resulted in an uneconomic level of costs before many nuclear plants on order or under construction were completed. New plant orders dried up almost everywhere and the newly forming German Green Party concentrated on issues related to nuclear power stations and nuclear weapons. Improvements in the efficiency of electricity use (in electric drive motors, lighting fixtures and appliances of all kinds) also slowed the demand for electricity despite a continuing increase in the number of uses. Economics, technology and environmental politics seemed to collectively conspire against nuclear energy for the remainder of the 20th century.

The late 1970s and early 1980s continued to witness shocking new environmental disasters, in the massive release of dioxin in Seveso, Italy in 1976 and the 1978 revelations regarding the massive burial in the 1940s and 1950s of toxic waste in the Love Canal, New York. However, this period also saw the first significant political backlash against environmental protection advocacy. Economic interests hurt by conservation measures and anti-pollution regulations became more aggressive in the defense of their interests. Neo-conservatism (usually called neo-liberalism in Europe) came to power in Great Britain, the US and elsewhere and was often determined to deregulate and to shrink government. Ronald Reagan opposed the protection of remaining remnant redwood forests and campaigned openly against air quality regulations in Ohio and other US coal mining regions. In office he appointed those who would roll back regulatory enforcement and who favored resource extraction interests. Environmental protection was no longer an uncontested motherhood issue; it had, in effect, come of age politically.

During the Reagan years pro-environmental opinion waned somewhat, but the commitment of those concerned grew as evidenced by an expansion of membership in US environmental organizations such as the Sierra Club. At the same time Australia saw a massive mobilization to oppose the Franklin Dam in Tasmania and green parties were created in many European countries. While environmental politics could not quite maintain the surge of the late 1960s and early 1970s, environmental activism continued throughout the period of low governmental responsiveness during the early 1980s. By the mid- to late 1980s a series of events, new concerns and new scientific findings brought a resurgence of wider public concern which led in turn to a new set of legislative and policy initiatives in the early 1990s.

The most dramatic and visible events of the period were: the catastrophic release of toxic chemicals in Bhopal, India (1984), the Chernobyl nuclear disaster in the Ukraine (1986) and the massive oil release from the Exxon Valdez off the pristine Alaska coast (1989). New or growing concerns included an array of problems associated with the disposal of municipal solid waste and the siting of landfills and incinerators, widespread concern with species loss especially in relation to the rapid cutting of tropical rainforests, and continuing concern with acid precipitation and with the disposal of toxic and radioactive wastes. New scientific findings also accelerated the renewed wave of environmental concern. Most notable of these were stratospheric ozone-layer depletion and climate warming resulting from the ongoing release of greenhouse gases. Of particular concern in this regard were the possibility of rising sea levels and possible threats to ocean phytoplankton and other basic life forms. By the late 1980s environmental matters were topping public opinion polls as issues of greatest concern. A new wave of environmental politics had begun and, as we will see below, both the environmental movement, and the response to it, was more sophisticated the second time around.

TWO WAVES IN CONTEMPORARY ENVIRONMENTAL POLITICS

In many nations interest in environmental issues, and in non-governmental organization (NGOs) and environmental movement activity, was higher in the periods 1968–1975 and 1985–1992 than at any other time. When one compares the two periods, both the most important issues and certain characteristics of the movement were quite different. The first wave saw the creation of some of the

leading environmental organizations and the environmental movement was at the time motivated primarily by new ndings, perspectives and concerns regarding pollution, the potential for future resource shortages (especially energy), nuclear power, and rapid human population growth. Politically, the rst wave was often highly confrontational and many early environmental advocates stood well apart in manner and viewpoint from mainstream society. The second wave raised some challenging new issues, but was generally more accepted by the wider population and in some cases, accommodation was sought by economic and political elite.

The early environmental movement in the rst wave sometimes displayed a signi cant apocalyptic and apolitical dimension. Modern industrial economies were seen by some to be on the brink of collapse, in danger of being suddenly overwhelmed by the pollution, diminishing resources (and the agrant waste of those resources), and out-of-control population growth. Only some of the information advanced in this period was carefully grounded in scienti c ndings, but the assertions struck a public nerve nonetheless and provoked governments, universities, and scienti c organizations to expand their environmental research capabilities, to reorganize research priorities and even to develop new interdisciplinary approaches.

As noted, it was in the early 1970s that many governments created environmental agencies and ministries. At the same time many universities, sometimes in surprising places, saw individual faculty and students direct research and teaching attention to a wide range of environmental issues. The locus for consideration of matters environmental could be as varied as departments of geography, political science, chemistry, biology, history, economics, or urban planning. Some interdisciplinary environmental studies programs grew very rapidly only to suffer enrollment declines as public interest waned somewhat (between the waves) in the late 1970s and early 1980s. Those declines con rmed for many critics within the universities that these issues and new approaches were but a ash in the pan and not, as claimed, a new and yet enduring approach to scholarship. Yet the declines were temporary and new sub- elds arose in everything from environmental ethics and economics to conservation biology and air pollution chemistry.

This altered intellectual and scienti c terrain in universities, and the wider learning within society as a whole, signi cantly altered the environmental politics of the second wave as compared to the rst. Throughout the 1970s and 1980s, graduates in environmental sciences and policy studies moved into ever increasingly professionalized environmental NGOs and policy consulting rms. Relevant government departments, previously predominantly populated by planners and engineers, added ecologists and other environmental scientists to their staffs and many engineering and law faculties, for example, added environmental components to their degree programs. Individuals with extensive NGO experience were hired by government ministries, or returned to graduate study and/or joined professional consulting rms or university faculties. By the time of the second wave (1985 1992), both the issues and the fundamental character of the environmental movement had changed. The movement itself had become highly professionalized (a change that was not without its critics from within and without the NGO community).

The second wave saw the re-emergence of preservationist and biodiversity concerns central to the conservation movement (dating back into the 19th century) and an increased interest in global issues. This contrasted to the rst wave where pollution and sustainability concerns dominated. The second wave also saw a more professionalized environmental movement provide ecological, economic, and legal analysis to government and to society at large. Environmentalism was much less on the fringe: environmental ideas were widely acknowledged and seen to be accepted by economic and political elite. A sophisticated array of technical options and policy tools was advanced rather than the vague notions of withdrawal from society and/or advocacy of crude end-of-the-pipe pollution controls so common in the rst wave. Environmental organizations discussed the importance of various taxation regimes, environmental user fees, governmental procurement patterns, environmental audits of industries, state-of-the-environment reporting, economy environment integration and sustainable development.

Society itself had become more environmentally sophisticated through changes over the years in public school curricula, nature and conservation television programming, and the sheer numbers of individual citizens directly affected by environmental concerns from smog to the siting of nuclear power plants, from the loss of a favorite woodland to the safety of drinking water or food. In the second wave, in Canada for example, environment economy round tables were established at all levels of government bringing together environmental activists, industry leaders, labor unions, and government of cials. Less well-known were the long-established links between labor unions and environmentalists in both the US and Canada dating back into the late 1960s through the efforts of the United Auto Workers Union and the Oil, Chemical, and Atomic Workers Union. In the 1990s the interactions, and sometimes, shared agreements were wider. Policy advances were sometimes made through these cooperative processes, especially at local level. More important perhaps, by the end of the second wave few participants saw the differences and distinctions between conservation and environmental organizations as important any longer.

More dramatic as a characteristic of the second wave was the introduction by industries and retailers in Europe, North America and elsewhere of a wide variety of so-called

green products. Many 1970s environmentalists would have been appalled at the very notion (and more than a few 1990s environmentalists had their doubts as well). Nonetheless, suddenly products with environmental claims were available from less polluting household cleaning products to energy-efficient lighting devices to road asphalt made from used tires to recycled paper and boxes. In Germany, Greenpeace entered directly into the business of producing energy-efficient refrigerators. Whatever the limits of green product practices, the introduction and wide acceptance of green products speaks to a considerable environmental capacity within both industry and society, and a very different style of environmental politics than in the more confrontational first wave. Also typical of this shifting approach were environmental audits and life cycle analysis, both tools used directly by industry to assess the environmental effects of their operations and products. Much changed in terms of the way products were made, recycled, and sold to environmentally sophisticated consumers, but as well the centrality of government regulation of industry had declined.

One way to understand these developments as a whole (from the late 1960s through the mid-1990s) is to see environmental capacity as having broadened and spread from environmental advocacy groups and universities into government agencies and the economy and society as a whole. Another way to understand the change is to see economic and political elite as becoming on the one hand more accommodating of some change, but also more sophisticated at delaying and at redirecting any calls for radical change. That is, the elite have become willing to shift products and processes where such changes are relatively inexpensive (and perhaps even profitable), but seek to deflect change from policies which would impact severely on profit margins or access to resources. Regardless of the overall accuracy of such interpretations, the second wave was different from the first and it too faded in the face of the economic difficulties of the 1990s. These recent challenges to environmental politics will be considered below, but first it is important to identify the principal institutional structures of environmental politics: environmental organizations and Green Parties.

ENVIRONMENTAL ORGANIZATIONS: GREEN PARTIES VERSUS NGOs

In many locations the environmental movement has gone from a political movement of individuals and NGOs to one which also includes adherents to a Green Party. Most European countries, as well as Australia and New Zealand (which can boast the first nationwide Green Party, the Values Party founded in 1972), now have Green Parties strong enough to have elected members of the legislature at the provincial (state) or national level. In the Australian state of Tasmania the Green vote has exceeded 30% of the total on occasion. In Germany and elsewhere, Greens have held the balance of power at the state level, entered the government on the national level and governed outright in the city of Frankfurt. But in few other countries have Green Parties been so successful; in North America the Greens are all but absent despite the long-standing existence of a strong environmental movement. Why have Green Parties not been more widely successful, one might ask? Why in North America and elsewhere has voting for Green Parties never approached the level of support for environmentalism that exists in terms of public opinion polls or in terms of membership in environmental organizations?

One reason for this limited success within electoral processes is that environmentalists have no consistent position on many political issues of great importance to many people. What is the Green position on gender or regional issues? What is the position of environmentalists on inflation, unemployment, drunk driving, abortion or appropriate levels of taxation? Clearly there is none in most of these cases. It could be said that environmentalism is a truncated ideology: socialists, conservatives and liberals have consistent views on most questions, environmentalists do not. Some environmentalists are quite conservative on economic and social issues, others are quite progressive. It is hard to hold a political party together when its members simply do not agree, or even in some cases care about, some of the leading issues of the day. Many voters wonder how could a Green Party govern; in government a party must make decisions one way or the other.

In addition, the road is difficult for any new political parties; the advantages of incumbency or recent incumbency are considerable. As well, Green Parties have succeeded almost exclusively within multiparty political systems, usually where there is some form of proportional representation (party voting, i.e., a percentage of the votes producing a set number of seats on a national or regional basis). In such a context Green Parties can more easily emphasize some issues and ignore others (or trade support on issues of lesser importance for gains on the environment). Only the Minister of the Environment in the coalition government of France formed in the late 1990s has been a Green. Green Parties work better in some systems than others. Where there are single-member constituencies, as in Canada, the US and Great Britain, Green Parties have not gained much ground, even where many people like *green* ideas. Usually, existing parties take up green ideas, whether there are successful Green Parties or not, so long as there is support for green ideas. These ideas have played an important political role for more than 30 years within widely varied institutional arrangements: clearly,

then, environmental politics does not always require stand-alone Green Political Parties.

In broad terms, political movements seek to influence society and/or government; in contrast, political parties seek to become the government themselves or to be directly a part of it. Both Green Parties and NGOs influence the way society and government function, altering some of the collective choices that are made and participating in a societal process called *agenda setting*. Agenda setting determines which issues are priority ones, which concerns get the most attention and resources, which are dealt with first and most frequently by decision makers. All interest groups including environmental organizations, the media, business, political parties and many other organizations are involved in the process of agenda setting.

A movement is not so formally organized as a political party or an interest group (NGO). Individuals in some roles and activities may be part of a movement without necessarily being members of NGOs or even seeing themselves as members of that movement. For example, a group of neighbors may oppose the siting of a landfill or some other facility with environmental dimensions, though some are opposed to many objectives of the major environmental organizations. Nonetheless, their opposition to the particular project in question should be understood as contributing to the wider environmental movement. That movement includes, as well the larger, established environmental organizations such as Greenpeace and the Sierra Club, thousands of smaller organizations, as well as many unaffiliated individuals. A formal organization has members, regular meetings, likely a constitution of some sort, a budget, and so forth. A movement does not, it is much looser and more variable than that, but it certainly is identifiable and visible.

The heart of the environmental movement and environmental politics has, in most jurisdictions, been environmental organizations; environmental public interest groups or NGOs. Some are single issue oriented and fleeting others are very large, even global in their scope of operations and some have continuous organizational histories of a century or more. It is not possible to present here anything like a full nation-by-nation list. There are many thousands of environmental organizations in North America alone. In the nations of the European Union more than 10 million individuals are members or active supporters of environmental organizations. One of the earliest European groups still in existence is England's Commons, Open Spaces and Footpaths Preservation Society founded in 1865. The organizations with the greatest global reach include Greenpeace (founded by Canadians, but with at one point approaching million members in, for example, the Netherlands), the Worldwide Fund for Nature (WWF) with activities on every continent, the International Union for the Conservation of Nature (IUCN) based in Switzerland, and Friends of the Earth International (FOEI).

Perhaps equally important are large conservation and environmental organizations based primarily within one nation: the Sierra Club, the Natural Resources Defense Council, the Wilderness Society, the Environmental Defense Fund, the National Audubon Society, the Nature Conservancy, and the National Wildlife Federation in the US. In Canada, in addition to Greenpeace and important parallel organizations of US or other origin, are Pollution Probe, the Canadian Nature Federation, the Toronto Environmental Alliance and the Western Canadian Wilderness Committee. Other important environmental organizations in the richer nations include: in Germany, the Bund fur Umvelt und Naturschutz Deutschland (BUND); in Denmark, the Danish Society for the Conservation of Nature (founded in 1911); in Australia, the Australian Conservation Foundation and the Tasmanian Wilderness Society; and in Great Britain, (in addition to large branches of Friends of the Earth and Greenpeace) a number of large, long-established, conservation organizations such as the National Trust and the Royal Society for the Protection of Birds.

Finally here it is important to identify several radical challenges to established environmental organizations. These challenges are ongoing and arise from many quarters, they continually prod larger organizations that inevitably become just somewhat more cautious as memberships and the size of professional staffs increase (and the need to raise funds and maintain membership size grows). Friends of the Earth was originally a split-off from the Sierra Club. The environmental justice movement, which emphasizes racial bias in the siting of environmentally undesirable facilities, has been very important in the US since the late 1980s. Numerous environmental justice grassroots organizations have been highly critical of the larger, more established environmental organizations for under representing visible minorities and their concerns. Also highly significant since the 1970s has been *ecofeminism*, a movement within a movement which focuses on environmental issues which disproportionately affect women, especially but by no means exclusively women within developing nations (Warren, 1995). As well, the ideas of *deep ecology* helped to encourage an animal rights movement, and such radical wilderness protection organizations as Earth First!, and in so doing restored something of a confrontational style within second wave environmental politics.

Also sometimes associated with a more radical strain of environmental politics is the simultaneous consideration of environmental concerns and the problems of poorer nations; here the movement has been pushed by such international groupings as the Rainforest Alliance.

THE COMBINED CHALLENGE OF ENVIRONMENT AND DEVELOPMENT

Combined environment and development concerns came to prominent attention in the 1960s with a focus on rapid human population growth, especially within poorer nations. At the time this attention often had a neo-Malthusian tone and frequently contained warnings regarding imminent and widespread famine. Radical and direct interventions to slow birth rates were seen by some as appropriate and necessary initiatives. Paul Ehrlich (1975), in his widely read *Population Bomb* (first published 1968), called for taxes (in the US) on cribs, diapers, and toys, followed by an aggressive anti-natalist foreign policy abroad. External policies were to include tying food aid to the adoption of strong population control initiatives by aid recipient nations. Ehrlich supported proposals in India for compulsory sterilization of males with three or more children. Garrett Hardin advocated state-issued licenses to reproduce, licenses which could be bought or sold on an open market. It is difficult to imagine assertions of this sort being put forward now and, needless to say, there were strong responses at the time as well.

Some decades later those anticipated-to-be-imminent famines have thus far been avoided through improved food production and non-coerced population restraint (especially in Europe and North America, but in other nations as well). Nonetheless, human population may well already be well past the environmental optimum, but public attention has turned more to development than to population considerations. Barry Commoner (1972), responding to Ehrlich, argued that environmental damage was more a function of technology choices than of human population levels (or even of affluence). He further argued that human population restraint would follow from advances in economic wellbeing. Other analysts have noted strong correlations between population restraint and social policy advances such as equitable education and work opportunities for women, rising economic expectations, wider availability of old age pensions, and access to health care for infants. In other words, family size declines with social and economic advance; people will have fewer children when there is hope that those they do have will survive and that they themselves will not, in old age, be dependent on their children.

Thus, while 1990s environmental advocates would still favor the universal availability of affordable birth control opportunities, the discourse on environment and development has changed very much since the 1960s. Population remains a concern, but the emphasis has turned to development, economic policy and equitable global access to resources. Following Commoner's response to Ehrlich were a series of other studies, which further altered our sense of these issues. In the 1970s one important shift in tone was visible in the differences between *Limits to Growth* (1972) and a follow-up Club of Rome study *Mankind at the Turning Point* (1974). Where the former emphasized the need to restrain human population, economic growth and resource use to protect the future, the latter emphasized the need to see growth as necessary within poor nations and resource and economic restraint as more appropriate in rich nations. Hungry people with few material possessions do not readily embrace blanket calls for restraint; global environmental politics required greater sophistication than that.

Malthusian approaches to environmental protection waned further still with the insights of Amory Lovins and advocates of appropriate technology, and especially with the work of the World Commission on Environment and Development (the Brundtland Commission). The 1970s and 1980s saw many insights into more environmentally benign housing, agricultural and energy technologies which also promised economic advance, especially within low-development contexts. Lovins' promotion of solar, wind and biomass energy production was an important part of this changing focus. The Brundtland Report, *Our Common Future* (World Commission on Environment and Development, 1987), however, helped to further shift the focus from a more or less exclusive focus on the environmental costs of economic advance to a more balanced approach which included as well the environmental costs of failures to advance economically.

Our Common Future advocated a balanced consideration of environmental protection and economic development (sustainable development) and asserted that both were necessary, more mutually supportive than mutually exclusive. In the language of the report:

> In most countries, environmental policies are directed at the symptoms of harmful growth; these policies have brought progress and rewards and must be continued and strengthened. But that will not be enough. What is required is a new approach in which all nations aim at a type of development that integrates production with resource conservation and enhancement, and that links both to the provision to all of an adequate livelihood base and equitable access to resources (39–40).

The goal of the Brundtland Commission was to help to create a global environmental politics which was large enough to contain development advocates (mostly from poor nations), environmental protection advocates (mostly from rich nations) and enlightened representatives of government and business.

It is not universally agreed that this attempt was successful, or that sustainable development is not an oxymoron. Nonetheless the discourse around the politics of environment and development has shifted a great deal. It is now widely known that some of the gravest environmental damage is linked to economic desperation. Few environmental advocates would deny any longer that economic growth restraint is equally appropriate everywhere or that there are not some opportunities for simultaneous economic growth and environmental protection, even in rich nations. Few

would any longer ignore the importance of economic and social advance to the achievement of human population restraint or suggest that birth rate coercion was either moral or effective. The larger question remains however, as to what economic activities need to be restrained where and how and whether or not it is possible to simultaneously give a free hand to the forces of global economic growth and to achieve either environmental or social advance. Concern regarding environment and development has now largely merged into a larger debate surrounding economic globalization.

GLOBALIZATION AND SUSTAINABILITY

In the wake of the Cold War, global trade expansion and global trade regimes have rushed to fill the vacuum and to make the entire world secure for mobile capital investment. In this new context, global investors can bring enormous pressures to bear on governments by even implicitly threatening to withhold or transfer investment. This new reality bears in turn on an important question in environmental politics; the centralization or decentralization of environmental protection. In general, the smaller the unit of government and the less economically diverse the political jurisdiction, and the higher the local unemployment rate, the greater the relative power of mobile corporations. Thus, in recent years environmental protection rollbacks have been widespread and at the same time much environmental politics and decision-making has moved to the international, treaty-based, level (*see* Environmental Movement – the Rise of Non-government Organizations (NGOs), Volume 5).

Before discussing environmental initiatives at the international level a distinction needs to be drawn between the fact of increasing global economic integration and the negotiated trade regimes, such as the North American Free Trade Agreement (NAFTA) or the General Agreement on Tariffs and Trade (GATT). When a firm can pay skilled manufacturing workers a dollar or two a day in Indonesia, China or Mexico, it can easily afford to pay quite high tariffs to sell into the US, Japan, or Europe. This is especially true if, at the same time, firms avoid legal protection for trade unions, workplace health and safety regimes, and enforced environmental regulations. Trade treaties do not cause these problems. They may help to speed the trading process, but trade treaties also provide a potential opportunity to harmonize (average) upwards, rather than downwards, on labor and environmental standards. As with the NAFTA Side Agreement on Labor and the Environment, there is no technical (as distinct from political) reason why trade treaties could not contain progressive social and environmental provisions. There is also nothing but a lack of political will (obviously no small matter) which prevents common (and enforced) environmental regulations, as is virtually now the norm within the European Union.

An impressive array of multilateral and bilateral environmental treaties have recently been signed; indeed, since the late 1970s environmental politics seems to be as often conducted at the diplomatic level as at the national level. Major treaties include: the Convention on International Trade in Endangered Species of Wild Flora and Fauna (1973, 1979, 1983); the Montreal Protocol on Substances that Deplete the Ozone layer (1987); the Basal Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal (1989); the UN Biodiversity Convention (1992); and the UN Framework Convention on Climate Change (1992, followed by the additional agreement in Kyoto, Japan in 1998). Quite clearly it is the case that many global environmental problems can only be resolved with the active participation of many, if not most, nations. The larger question, however, is how effective is signing any number of international environmental agreements when there is no effective international enforcement?

Moreover, the new realities of global corporate mobility and widespread employment vulnerability have enormous implications for environmental politics. Even in the richest nations, as well as in local government circles and among employees everywhere, there is now a thoroughgoing political timidity. Every government now fears losing employment, investment, and tax revenues. Almost any social behavior (even including child labor) is somewhere justified in terms of global competitiveness and employees and firms everywhere must compete with that new standard. No level of profit, or level of executive or product endorsement compensation, is seen any longer as unacceptable. Further, what would be seen in Europe or North America as environmentally intolerable, even outrageous, behavior, is almost expected in Nigeria, Indonesia, or Guyana, even when good corporate citizenship prevails on the environmental front in the Netherlands, Canada and/or the US.

Interestingly, some of today's billionaires, not a reborn political radicalism, are often the very people raising questions about the need to find ways to balance corporate power in the age of globalization. George Soros (1997, 47) argued:

> Laissez-faire capitalism holds that the common good is best served by the uninhibited pursuit of self interest. Unless it is tempered by the recognition of a common interest that ought to take precedence over particular interests, our present system is liable to break down.

James Goldsmith (1994, 17), the perhaps eccentric British/French billionaire is more direct:

> ••• 47 Vietnamese or 47 Filipinos can be employed for the cost of one person in a developed country, such as France. Until recently, ••• 4 billion people were separated from our economy by their political systems, primarily communist or socialist, and because of a lack of technology and of capital. Today all that has changed. Their political systems have been transformed,

technology can be transferred instantaneously anywhere in the world on a microchip, and capital is free to be invested anywhere the anticipated yields are highest.

Many in the world of environmental advocacy would conclude from such views that global economics requires global environmental and social standards; that is, that an economically integrated globe needs more political integration, not less. They conclude that if Southeast Asian forest workers earned even half the wages of those in the Pacific Northwest, the rate of destruction of tropical rain forests might well slow considerably, and simultaneously development would advance. Similarly, if Caribbean bauxite miners were paid half what a miner would earn in Germany, there would be less aluminum that was not recycled. There is now broad agreement that the economic, the social and the environmental are tied together in numerous ways; and that environmental advocates must work towards a consistent position regarding all three. Employment insecurity, it is agreed, undermines environmental concern, in both poor countries and rich. Environmental politics in the 1990s and beyond may well be moving toward greater integration within the broader political, and toward including in its expanded purview many aspects of social and economic policy.

Expanding the purview of environmental politics at the intellectual level revolves around the rising importance of sustainability. This shift within environmental thought is especially pronounced in European environmental politics which are increasingly in the 1990s leading the way worldwide (and where wilderness issues have never had the salience that they have had in North America). One new approach to sustainability analysis is *ecological footprint analysis*, which concludes that it would take three Earths of resources to bring the whole of the human population to present North American living standards (Wackernagel and Rees, 1996) (*see* Ecological Capacity, Volume 3). This analysis, however, assumes that the gains in the poor nations will be based on the energy and materials consumption patterns of today s richest nations. That need not be true. One can envision a gross domestic product (GDP)/energy and materials ratio three or four times what is achieved at present, but this might still leave us several planets short should human population indeed double again as now seems all but inevitable.

In the end, if one prefers a world that is both more equitable and environmentally sustainable, it is hard not to be open to the idea that the rich nations are rich enough, at least in terms of energy and material consumption. It would seem, though, that the poor everywhere could hardly use less of anything than they presently do without nding ways to gain in quality of life while holding their ground in terms of energy and materials use. Environmental politics must stress such things as the introduction of high quality, low cost public transportation, especially as replacements for broken down, fuel inef cient automobiles. Also hopeful are demand-side management (DSM) initiatives by energy utilities directed at the needs of low-income customers. Nonetheless, it may well remain the case that the rich in the rich countries cannot be easily and sustainably supported even at present consumption levels and patterns if the more numerous poor everywhere are to advance signi cantly in the same terms. Politically, this view would seem all but impossible in the present context, but one might speculate that if there is to be a successful third wave in environmental politics it will come at the global scale and focus on sustainability and equity issues.

Thus, two of the best prospects for future environmental politics in a globalized world are: (1) accelerating the adoption of technologies such as those outlined by von Weisacker *et al.* (1998) in *Factor Four* and (2) developing a global politics which would promote the distribution of fair shares of ecological space as outlined in Carley and Spapens (1998). The rst of these works contends that we must, through ef ciency gains and the de-materialization of GDP double global wealth while simultaneously halving resource and energy use. The second work advocates calculating resource use at the national level and comparing that use level to a national fair share of sustainable resources calculated on a global or regional basis. The educational power of such calculations could be considerable. The political challenge then becomes to nd ways to accommodate development based on that fair share without a loss in quality of life for those currently well off.

Environmental politics would seem to have come a very long way in four decades: from local pollution issues to global multidimensional concerns, from seeing environmental issues as largely separate from distributional issues to seeing the two as bound up together. A long road has been traveled and progress has been made, but the challenges have not gotten smaller.

Global Environmental Change and Environmental History

IAN G SIMMONS

University of Durham, Durham, UK

To try and extract some of the ideas which intertwine with the environmental changes wrought by humans in the last 10 000 years, an agreed empirical historiography of change is needed. The article suggests that the major world-wide periods of human history for the present purpose can be determined by the type of economy pursued. In effect, these are periods which are characterised by access to energy sources and hence to the technologies available: these properties allow a society to change its surroundings, providing it has occupancy of the land and water for a suf cient time. Materialist historiography has always taken very seriously the notion that the ways in which people made a living were central to their other values and that technology drove history. The story of what has happened, where, and when, is well-documented at global, regional and local levels but less well developed is: (a) the relationships of such metamorphoses to changes in human thinking; and (b) whether all these alterations present history simply as 'one damn thing after another' or whether there are emerging narratives of process in which we can see patterns emerging with a 10 000 year relevance.

THE EMPIRICAL NARRATIVE

The first item in Johann Sebastian Bach's will is his share in a Thuringian coalmine. That fact can be seen as a nexus between a local environmental change, a global shift in economy, a family in its household and his searing representations in music of order and faith which comprise one of the high achievements of Western culture. But is there any connection between these statements other than that of being symbols on a piece of paper? How does the economy of a family, a region or a country or the world link to their ideas about the world or do all these aspects float free of each other, with only coincidence in time in common?

To try and extract some of the ideas, which intertwine with the environmental changes wrought by humans in the last 10 000 years, an agreed empirical narrative of change is needed. Much of this is provided in other sections of this Encyclopaedia and only a summary is given here. Table 1 suggests that the major world-wide periods of human history for the present purpose are determined by the type of economy pursued. In effect, these are periods which are characterised by access to energy sources, and hence to the technologies available: these properties allow a society to change its surroundings, providing it has occupancy of the land and water for a sufficient time. In this article the emphasis will be on the relations of those observed alterations: (a) to the metamorphoses of human thought that accompanied them; and (b) to emerging narratives of process which we can construct with hindsight. A coda ponders whether there are lessons for today and tomorrow in this kind of hybrid-knowledge fabrication.

Human history is reduced to economy in Table 1. This provides a starting point in the sense that materialist historiography has always taken very seriously the notion that the ways in which people made a living were central to their other values and that technology drove history. In the other direction, it is obvious that the environmental impact of a hunter-gatherer is likely to be less than that of a bulldozer, except that the one economy has in fact taken up about 90% of human evolutionary time and the other is (even loosely interpreted as any industrial economy based on hydrocarbons) only 200 years old; the bulldozer is largely a post-1940 development. Thus although the access to energy and technology of solar-powered agriculturists was restricted, their tenure of the earth has been long, and they have penetrated into some environments whose resilience in the face of their impacts was limited. The use of tabular format rather hides the fact, of course, that not all hunter-gathers have disappeared, and that there are some farmers who have little access to industrially produced materials. In both cases, a revival of the older ways is being promoted in some regions of the world. Nevertheless, the changes wrought by the industrial way of life and its

Table 1 Global environmental history: a periodization[a]

	Dates: approximately	Energy sources; Energy consumption	Technology	Impacts
Hunter-gatherer	10 000–8000 BCE	Solar energy captured recently as biomass 5000 kcal cap^{-1} day^{-1}	Stone, bone, basket, skins, wood	Localized but significant in marginal species and habitats
Agriculturalist	8000 BCE–CE 1750	Solar energy captured recently as biomass, wind and water 26 000 kcal cap^{-1} day^{-1}	Addition of metals plus sophisticated construction methods, specialised tools; domesticated biota	Global impact of agriculture on soils, water and land-forms: e.g., the terrace transfer of species on all scales
Industrialist	CE 1750–1950	As above + stored solar energy as fossil fuels 77 000 kcal cap^{-1} day^{-1}	Intensification of material use in cities, as chemicals, as effluents, as machines	Intensification of impact and spatial extension
Post-industrialist	CE 1950–	As above + nuclear energy and alternative sources of solar-based energy 230 000 kcal cap^{-1} day^{-1}	Electronics; genetic manipulation	New chemicals and new genetics create uncertainties on larger scale

[a] All rows contain the influences in the rows above them unless explicitly excluded; cap, *per capita*.

post-industrial successor (which has the ability to generate large amounts of capital and spin it off into almost any part of the globe) cannot be gainsaid. An electricity-powered economy with a high proportion of services is sometimes labelled *post-industrial* but although it may call in resources from a low-energy, low-information periphery, it exerts many strong influences upon the world's ecology. It is fundamentally responsible for much of the appropriation of Net Primary Productivity by human societies, which now amounts to about 40% of the global terrestrial total. If the pre-agricultural terrestrial biomass was about 842×10^{15} g of carbon, the present figure is, according to Matthews (1984), 737×10^{15} g of carbon, a reduction of 12.4%. In spatial terms, this means that although 51.2% of the terrestrial surfaces can still be described as undisturbed', if rock, ice and barren land is taken out of the total, then that category totals only 27.0%. As calculated in economic terms, ecosystem services are worth about $33 trillion per year, which compares with the gross domestic product (GDP) of all the world's nations at $18 trillion. Employing energy use as a surrogate for environmental impact, the current level of impress is 13.1 terawatts (TW); a human population of 12 billion people with a more evenly distributed access to energy might produce a footprint equivalent to 90 TW.

The story of what has happened, where, and when, is well documented at global, regional and local levels. What is less well developed is: (a) the relationships of such metamorphoses to changes in human thinking; (b) whether there are emerging narratives of process in which we can see patterns emerging with 10 000 year relevance. So this essay will attempt to discuss both an *ideational narrative* in which a history of ideas is interrogated for its relation to what actually happened in the world and a *narrative of process* in which longer-term processes are plucked out of the multifariousness of history for further examination.

THE NARRATIVE OF IDEAS

Two avenues will be followed here. The first is the discussion of ideas, which seem to be connected to economies quite closely. If they are connected to economies: then they are bound up in the webs which link ecology, human use on the ground and what humans perceive in their minds. The second is the opposite: those actions and attitudes, which seem to float free of the economies and ecologies of their time.

Any reasonably accurate long-term perspective on human–environment relations can only be made by the historically well-informed. Those who relied on especially

partial stories are likely to have constructed different views of the unfolding of society from those who had extensive assemblages to consult. An early symbol of the desire for inclusive compilations of knowledge is the model globe. The significance of early examples such as that made by Martin Behaim in 1492 and annotated with the nature of commodities and business opportunities throughout the known world can scarcely be underestimated. Behaim's globe, for example, was used to sell Magellan's projected voyage to sponsors (Jardine, 1996). The gatherings of the 18th and 19th centuries take on a special significance, starting perhaps with the *Encyclopédie* of 1751–56. A fundamental example is the ambitious aim of Alexander von Humbolt (1769–1859) to depict in a single work the entire material universe which led to his multi-volume *Cosmos* of 1845–1862. The detailed results of Charles Darwin's global voyage, and his later observations and experiments also typify the desire to accumulate comprehensive bodies of knowledge, though Darwin (1809–1882) lacked the cosmic aspirations of Humboldt.

No study of material-ideational links can ignore the centrality of Karl Marx (1818–1883). The environmental aspects of Marx are implicit rather than explicit and urban–industrial rather than global–historical. Nevertheless, he viewed the integrated development of a political economy as a humanising, socialising and indeed internalising of natural substances and forces in the environment. According to Marx, therefore,

> The mode of production in material life determines the general character of the social, political and spiritual processes of life. It is not the consciousness of men that determines their existence but, on the contrary, their social existence which determines their consciousness.

So one environmentally-oriented interpreter, Parsons (1977), is able to say that for Marx all human values, whether economically-linked like food, or higher values like music, have their ultimate origin in non-human nature. Yet Marx does not attempt to define the equivalent linkages for pre-industrial economies in the detail that he applies to the separating and alienating effects of industrialisation in the context of the social relations of capitalism. Followers and explainers of Marx have tried to work out a deeper historical sequence. Ted Benton, for instance, has asserted that the theory of nature–society relations which is developed in *Capital* is incapable of conceptualising today's population–resource–environment interactions. Benton's reconstruction (1996) of the intellectual resources of Marx and Engels brings forward the notion that development is not a unilinear quantitative expansion of production but rather a range of qualitatively different ways of realising human social possibilities. Marxian analysis of pre-industrial societies may need to build upon *Capital* rather than simply apply it.

Another attempt to interpret material history is espoused by Karl Kautsky (1854–1938). He attempted to show parallels between the processes of nature and those of human history. The non-human environment was in fact human-created or at least much modified in many aspects and therefore its evolution was social. Nevertheless it had material connections since for him every social innovation originated in the last analysis from a new technology. Thus technology is a predominant mediating influence between the natural environment and human societies (Kautsky, 1988).

A more recent re-statement of some of these notions has come from Max Oelschlager (1991), from whom there are assertions such as:

> once the agricultural turn was made, philosophy and theology sprung forth with a vengeance ••• the crucial interaction between existential and conceptual materials – lying at the heart of cultural process and the ecological transition – increased in both frequency and pervasiveness ••• ideological reconstruction was inevitable. And ••• The idea of nature as a machine was deeply rooted in the experience of the Industrial Revolution and the pervasive influence of machines on life.

The first of these statements traces its connections in part at least to the surpluses created by irrigated agriculture: philosophy may bake no bread, but an assured supply of bread enables philosophers to live. The second reinforces the Kautsky directive that technology is a key mediator between humans and all else. The development of fossil fuels has clearly allowed profound transformations of social structures to take place. New work groupings and new social groupings with specialised interests are examples. Goldblatt (1996) argues that industrialism does not cause capitalism (nor its environmentally degrading effects) but it does unleash it. It would be generally agreed that access to energy sources and to technology are principal factors but not *the* principal factor; they must be considered in relation to all other aspects of the social order.

In Smil's (1994) collection of work on business cycles in the West, there is a confluence of material change with economic life. This can be interpreted to show a coincidence between new energy sources and innovative prime movers on the one hand, and accelerated investment on the other. Innovation in energy technology and access falls in the middle of a business down-cycle and its adoption then coincides with the rise of the new upswing. The sequence suggested comprises: (a) the upswing of 1787–1814 is related to the development of coal and the stationary steam engine; (b) that of 1843–1869 is connected to moving steam engines in the forms of the steamship and the railroad, together with improvements in iron smelting; (c) that of 1898–1924 with the introduction of commercial electricity in the form of electric motors in factories; (d) the period around 1937 which coincides with the gas turbine, fluorescent light and the discoveries in nuclear physics;

and (e) the phase that was ended in 1973 by oil producing countries (OPEC), which had cheap oil, and the extensive and unquestioned use of the motor vehicle and nuclear fission power.

The ideational effects of these surges are difficult to trace directly, but there can be little doubt that each of them helped to strengthen the Promethean aspects of the western world-view. Grubler (1994) suggests parallel developments in western agriculture: innovation up to the mid-19th century, mercantilism from 1850–1935 and industrialization from 1935 to the present. Each of these was a cluster of biological, mechanical and social/organizational change, with the social sometimes preceding the new crops and new techniques. The idea of social structures founded upon the dissipation of energy is a meta-narrative that takes off from these abstractions and turns them into a general model.

The classic work on the long-term relations of the natural environment and all facets of human societies is that of the Annales school of historians, and in particular the central figure of Fernand Braudel (1902–1985). He wished to understand patterns of nature as well as history, so that a radical inter-discipliniarity might be accomplished, using the insights of other social and natural sciences. If a long enough period of time was inspected, then not only the history of events (*histoire evenmentielle*) might be better linked to the world in which it was situated, but the *longue duree* might the better include environmental change, which was seen as proceeding along a much slower time path than changes located solely in human actions. Braudel (e.g., 1972) saw environmental transmutation as the slowest vector in the whole society-nature complex, a point on which later appreciations of the rapidity of e.g., a climatic change or the onset and progress of soil erosion might well take a different view. In the end, though, the Annales view is of a complex rhythmical web in which environment has to be given a place but cannot crassly determine the nature of a society. If environment is often critical (in terms of the juxtaposition of mountain and sea in the Mediterranean basin, for example), it is rarely as direct as in the example of snow being brought down in summer from the Alps to Italian cities being the origin of the making of ice-cream. The tone is more of environmental than economic determinism.

The French attempts to make long-term connections between economy and society are also exemplified in the work of Georges Dumezil (1898–1986). He had the idea that the diverse cultures of the Indo-Europeans (from Iran to Scandinavia) could be constituted in terms of the three functions of sovereignty, war and production. This last was, according to one commentator (Littleton, 1982), the least important (comprising the herder-cultivator stratum) and so perhaps accounts for its lack of detailed treatment compared with the other two, in his major outputs. In view of the endpoint of Dumezil's analysis of the extent to which a common linguistic ancestry is necessarily accompanied by a common social and cultural heritage, this seems like an opportunity missed. The same is true of Toynbee's great compilations (1976) of historical change which are heavily weighted in their treatment towards early civilisations. In these the causation runs from environment to religion and economy and the values do not stem in an obvious fashion from economy; periods of breakdown relate to political and social events, not rooted in an economy's structure. The advances of Islam into Europe in the 16th century or the Hellenic demise of 431 BC are little connected in any direct fashion with the imbalances between population, resources and environment in those regions at those times.

One of the most complete attempts at linking economy and the non-material has come with the work of Thompson (1989). He articulated a number of global phases of an economic type, beginning with early agriculture along the margins of the mountains of south-west Asia and ending with a Paci-c Shift which corresponds largely with a post-industrial society. For each of these, he posits a series of intellectual and social characteristics, among which science and religion are numbered. The sequence does not include a speci-c hunter-gatherer era but it is not dif-cult to add one. Nor is it dif-cult to add some other environmental linkages, such as dominant environmental pathologies and rates of population growth. One implication is that these are world-wide categories which transcend the varieties of culture found in, say, Europe, Africa and Asia. The descriptions given by Thompson, when translated to tabular form, make it necessary to remember that the transition from one category to another is regionally asynchronous. However, the work is certainly suggestive: the tying-in of a speci-c type of religion to each economic phase raises interesting questions and taken together, each row might be said perhaps to constitute a worldview, if the cells are verbally connected and scanned for their emergent attributes.

The notion that each stage of social change corresponds to its own types of law, government, religion (and other characteristics) was a major achievement of Giambattista da Vico (1668–1744) but who did not develop very far the notion of economy as a propellant of such change. His cycles of civilisation, in which divine, heroic and humanist phases went round more than once, did not attach themselves to, e.g., hunter-gatherers, irrigation agriculture and Mediterranean pastoralism. He did however suggest that Latin was a language which had evolved in a forest environment, making a case for the evolution of words like lex, ilex, aquilex, legumen and legere from a sylvan environment. But as Berlin (1992) points out, Vico's main contribution to thought is his distinction between the natural world as knowable but not intelligible, and the human world as knowable and intelligible. Because we made it; the suggestion, contra Descartes, that a reconstructive imagination

(fantasia) was a third kind of knowledge needed by students of history, seems to have a great deal to commend it.

The summation of this type of material seems clear: that in a few cases there seems to be a direct connection between the economy and some at least of the non-material values of a society. The attachment seems to be closer in solar-powered, pre-industrial economies, despite the assertion of Marx that all values arose from economics and class structure. In a sense this parallels the arguments for environmental determinism, which has always held more appeal in pre-industrial contexts, though it is clearly not absent in a post-industrial world.

DISSOCIATED TRENDS

If the links between economy and environmental values cannot be traced easily for the apparently obvious examples by the well-known analysts discussed above, then it is not surprising that a number of less obvious connections can be aired. One result of ranging across 10 000 years of change is the provision of examples to suit almost any taste in narrative. Rather like the Bible, something can be found to bolster any point of view. It is scarcely surprising then to be able to find examples of environmental thought which bear no perceptible relationship to the material circumstances of their origins and development. Culture, say Harvey and Reed (1994), can take on the features of a chaotic cascade of symbols and ideas that have a life of their own. Hence humans appear to make themselves.

To take one example: if we accept the magnitude of the Classical Greek achievements in both chronicling their own past as well as in thought about humanity and nature, then it is difficult to tie much of this to the particular agricultural economies of the time. Those economies had been in largely the same condition for centuries before the efflorescence of thought that we associate with the golden age of Greek philosophy and history. There is one possible exception to this: in the soil erosion of Attica, the Epicureans found confirmation for their view that the earth was senile, overpopulated and generally on its way to perdition. If indeed their outlook can be traced to the combination of fire and pastoralism prevalent on the mountains of Attica, there is a powerful link (Hughes, 1994). Even so, the actual course and intensity of the soil erosion has been disputed and its general role may have been exaggerated. But a false report is not necessarily any less influential than a true one.

A parallel ambiguity can be seen for the Renaissance period in Europe. Again, it is possible to interpret this as a flowering of a particular culture, which bears no relation to major changes in production from the land. It is true that nature is relevant, as can be seen in the loving depictions of landscape which now become a part of so many paintings. Initially of the background but in the case of Piero di Cosimo and the school of Giorgione, both around the turn into the 16th century, nature occupies much more of the frame, yet once more, no obvious connection with regional economic change is apparent. The contextual factor to be considered, perhaps, is that of increasing wealth, pride in ownership and in security made possible by trade and technology. Medieval Europe may not have been static technologically though less developed than China in terms of inventions, it had acquired a quantitative approach to matter, according to Crosby (1997). It is possible to suggest that advances in technology during the medieval centuries enabled societies to flourish in which the developments of thought, art, and consumption which could be later constituted as The Renaissance, were cultivated. But the really revolutionary ideas of the period and its aftermath, such as the new cosmologies of Copernicus (1473–1543) and Galileo (1564–1642) where, as John Donne (1572–1631) put it,

> ••• new philosophy calls all in doubt,
> The element of fire is quite put out;
> The sun is lost, and th'earth, and no man's wit
> Can well direct him where to look for it.

are certainly little related to energy efficiency, climatic change, or soil type.

Later centuries show some similarities. Keith Thomas's book (1983) on the re-valuation of nature in England in the years 1500–1800 argues that in many ways the men and women of those years developed a willingness to be more tender towards the living but non-human components of their world. But nowhere does he hold that these are strongly related to material change. He associates a new kindness to animals with the oncoming of industrialization (both in Britain and elsewhere in Europe) but thinks that the conditions for it were in place by 1700, rather before any strong manifestations of the new order. Yet as he says, if the prerequisites were latent in the Judaeo–Christian tradition, why did they emerge at a particular time and place, if it were not for changes in social and economic conditions? The point of nexus for him is the greater use of working animals in the sight of well-to-do townsmen or the clergy, though he embeds this in a wider context of cultural and social practices, mostly of a pre-industrial type. Possibly the growth of city living is more important than the primary economic type; there appears to be no major technological changes of a mediating kind.

In her account of western ideas from the hunter-gatherers of the Americas through to sustainability, Merchant (1995) constructs an inclusive history in which the story of Western civilization since the 17th century can be conceptualized as a grand narrative of fall and recovery. The story is carried by the three subplots of religion, modern science, and capitalism. None of these, we may notice, enforces a particular economy, though capitalism and industrialization seem to be umbilically linked outside the former Communist nations. Individual values therefore are attached

to this narrative as a whole rather than major changes in material circumstances. The same might possibly apply to other meta-narratives; in a different interpretation of Western ideas, Arran Gare (1993) details the withdrawal of philosophy from any attempt at totalizing of knowledge: it no longer deals with the whole world's interactions of nature, history and society. In large measure, this is caused by a drift down the centuries towards the dominance of nihilism. Its current end-point is a highly individualistic society, which involves an extreme detachment from, and instrumentalization of, the world, whether that world be of nature or of other people. People in particular are not participants in the stream of life and in the becoming of the world but transcendent consciousness in a world of things which are only externally related to each other. The watchwords are reason, foresight and efficiency. The connections to material conditions are at most secondary.

This last point seems to emerge from many studies of the possibility of technological determinism, where a considerable body of opinion declares that technology constrains but does not determine. Even highly-coupled technological explanations of socio-economic change cannot account for all the variance in the historical picture: Bimber (1994) argues that even Marx was not really a technological determinist. But there are hard versions of technological determinism in which a sequence of technological development prescribes an evolutionary path for societies irrespective of their social and cultural practices. A softer version would apply this to industrial capitalism but not previous periods of history. Overall, technological determinism looks more convincing over big sweeps of time and place, but the picture seems more contingent at smaller scales. At both, the alternative to a kind of total freedom for technology is its social production. It is becoming increasingly clear that the gender relations of a society will be important in these kinds of connections.

AGENCY AND STRUCTURE

In any summary of worldviews, therefore, the self-image of the human being is intimately bound up with what can be technologically achieved but which then feeds back in a self-aware view of him/herself that must surely affect human–environment relations but at a remove. These images might include: (a) the economic man (sic) of the post-Enlightenment period who is individualistic, materialistic and utilitarian; (b) the competitive individual beloved of the Social Darwinists; (c) the people who were successful because they could deal with the base instincts revealed by Freud; (d) the reductionist product beloved of psychologists who think that behaviour will someday be totally explicable at the molecular level; and (e) the notion that humans are essentially *spirit* in a contingent animal casing. None of these appears to be closely coupled to the evolution of different types of economy. Yet neither are they irrelevant to the construction of the Western worldview, which is now so dominant in all its aspects, including that of environmental thought. The bringing forward of the fragment and of the instant moment seems not to have diminished a belief in an ordered cosmos. Uncertainty within limits seems to be the only reasonable judgement upon the apparent free-floaters: like a kite in unskilled hands, there is a lot of swooping about even if the strings are finite in length.

FRAGMENTATION

Any world chronicle furnishes examples of social changes, which can be interpreted as producing societies in which the demands of the individual are addressed before those of the polity as a whole. Some of these metamorphoses also lead to instrumentalities where the non-human world comes very low in any list of priorities.

In such an account of the Holocene, the starting point can be taken as our reading of hunter-gatherer societies which live within the compass of a unified mythology. The worldview thus engendered may well encompass all aspects of life: the relations between individual humans as well as between the group and its food sources are all referable to the same mythic structure as the social agglomeration and its place in the cosmos. It seems unlikely that such myths always provided for harmony among people or for an unfluctuating relationship with resources (and so should not therefore be romanticised unduly) but nevertheless it provided a coherent explanation of uncertainties at most temporal and spatial scales.

Very similar mentalities may have pertained in the earliest agricultural communities of the hill-lands of the Levant but once successful irrigation agriculture was established in the basins of great rivers (such as the Nile, Tigris–Euphrates, Indus and Huang He), then stratified societies might emerge. They contained classes of people who were devoted to e.g., government, religion, or artisanship and so were no longer in daily physical contact with soil, plants and animals in the way that is inevitable for a hunter-gatherer. Such trends are obviously, intensified in urban societies, though the small absolute size of the pre-19th century city must not be forgotten. Thus both for the townspeople and the farmers, the natural world is potentially an instrument of a cultural set of ordinances and not an intuitively perceived flow through the quotidian existence of all (Shepard, 1982). For some interpreters, this can be seen as the beginning of the regarding of nature as part of the *Other*. The relationships of this type of economy become closer after the development of fossil fuel energy in the 19th century. Modern technology has proved to be a fragmenter of myths, economic systems and land cover systems alike.

Yet between say 5000 BCE and 1800 CE, the world was dominated by economies which depended upon recently-fixed biomass for their existence (Simmons, 1996) and within this pre-industrial world, some trends of social individuation can be discerned. For example, the communal life of the manor in medieval Europe was altered by the withdrawal of the lord and his lady to private apartments behind the hall, a change which eventually resulted in the 17–18th century development of the corridor, allowing genuinely private rooms, especially bedrooms. Stronger movements towards social privatization – from openness to seclusion – start in the later Middle Ages (in Europe at least) and accelerate around 1800. Hence they partly coincide with and partly precede the development of industrialisation, with its reliance upon technology and its subsidy of current biomass by fossil fuels. Instances might include the banishment of (normal) death in public from the middle of the 18th century, death by execution in public disappears (mostly) between 1770 and 1870, and around 1800 prisons and madhouses cease to be public spectacles for the curious. Further, ca. 1800, the private enclosed space of the nuclear family begins to dominate in the west (Spierenburg, 1991).

It is not surprising, then, that further and different kinds of drawing apart should come to pass in the 19th century, given all the innovations of all kinds that the century provided. Steiner (1989) proposes that the 1870s were the critical time, with the poetry of Stephan Mallarme as the emblematic event, since it first explicitly dissociated word from meaning (his words reached out in all directions towards other words and images, being fluid, ambiguous and suggestive, according to one critic) clearing the path for modern semiotics and eventually, an idealist view of the world as being only language. Yet, Mallarme can be seen to have written at a time when many connectivities were being severed. Examples include the pointillisime of Seurat, the making of moving films as images per second, the pictures without object of Kandinsky, the loss of tonality in Schoenberg's music, the atomistic science of Cajal and the invention in Cuba (then a Spanish colony) of the concentration camp (Everdell, 1997). The shifts of 1870–1910 can perhaps be summed up in the transitions of the paintings of Piet Mondrian in those years or given a coda in the anxious splinters of T S Eliot's *The Waste Land* of 1922.

More recent developments include the individuation of entertainment and communications via the Walkman, the VCR (video cassette recorder) and the mobile telephone, the display of the dissected innards and body parts of animals as high art, the withdrawal of public broadcasting in favour of owned channels and its parallel in transport. There has also been a rise in the fragment rather than the prolonged: concert promoters speak of the increased popularity of shorter pieces (so performances of Dimitri Shostakovitch's 7th Symphony [80 min] are getting rare). TV programs gravitate to the magazine format rather than any extended treatment, with children's programmes becoming a total whirl of short spans and desperate camera angles. Most significant of all has been the replacement in more than one national culture of the 5-day cricket game as the norm by various shorter and more colourful versions.

Is there any reflection of these long-term events in environmental connectedness? To quote a set of parallel examples is certainly not to establish a causal relationship. But it is not very difficult to see the setting out of different land cover and water use systems, which differentiate between production, pleasure and nature. In the case of the first, common property resources have undergone constant attrition through several thousand years: the open fields of Europe have steadily become privately owned in the name, largely, of more intensive production. Much open and commonly held land was enclosed and reclaimed as soon as legal and technological systems allowed, examples can be found from the Fens of East Anglia to the American West. The second category can be seen in the way special places are set aside for recreational use in rural areas: the right to roam of e.g., Sweden is a rare phenomenon. Eventually there is the nature reserve and the wilderness in which wild nature (even pristine ecosystems if these can be proven) is set apart in a legal and often physical sense from the rest of the region in which it is situated. The UNCLOS (United Nations Conference on the Law of the Sea) findings attempted to apply the same trends to the oceans. The end-point of this group is found in the assertions of environmental conservatives that only total private ownership of resources and environment will prevent degradation.

COALESCENCE

For many discernible long-term trends in human affairs, a counter-current can be found. If we look at 10 000 years of human history and its relationship to natural history, comings-together can be discerned as well as drawings-apart.

One of the earliest was the formation of empires, which covered large areas and facilitated within them certain uniformities. The Roman Empire, for example, imposed a largely uniform legal system from the Levant to Wales. Thus as early as the 15th century it would have been possible to trade a small and valuable item from Ireland to Japan. Similar processes were carried further by later imperia based on industry; the coalescence of these and earlier world systems has been chronicled by Wallerstein and his critics (Frank and Gills, 1993). The present-day equivalent seems to be the globally instantaneous electronic telecommunications that spin a digital web round the earth rather like candy-floss round a fairground stick. The difference between the 15th century and today is perhaps the way

in which that system is, above all, devoted to processing the symbols of capital and allowing gobs of them to spin off and alight in one place or another to be the sweeteners of various developments. As well as the spinning of money, there is now the transfer of verbal information and image on an instantaneous basis via the Internet. It is easy to over-estimate the influence of such a device since its distribution is rather limited and its driving forces, initially anarchic, seem to be coming under the control of big players. But as an embodiment of Vernadsky's conception (1945) of the *noosphere* (a mind-sphere equivalent to the biosphere and atmosphere; *see* Noosphere, Volume 5), it comes closer than anything so far experienced, more so even than cheap travel by jet aircraft. For capitalistic modernism, the metaphor of the machine for both humanity and nature seems appropriate; the post-modernist world of virtual money seems not yet to have developed a comparable meta-metaphor.

The binding systems with environmental linkages are often of a hybrid human-nature type like the oceans and atmosphere. Not only were these globally interactive in their natural state but the human impacts upon them have the potential to be spread globally. Some influences are coalescent: that of the greenhouse gases is well documented and there is a persistent worry that there could be an equivalent in the oceans since they receive all the substances put upon the land and among these are many compounds toxic to life. The couplings revealed by intensive study of the temperature regime of the Pacific Ocean carry the implicit suggestion that any human-induced global warming may affect the frequency and intensity of for instance El Nino events. All these add up to a world in which the driving force of a population growth, which arrived at 6 billion in 1999, cannot be ignored at any scale. Demographic change can be seen as a non-reversible binding force which determines the size of the gyre which links humanity and nature, as indeed does the degree to which societies have access to commercial energy (Adams, 1988).

Can these trends bring about coalescence and bindings within the organic and human spheres? Without doubt, there are material changes consequent upon empires and trade. The Roman Empire was the cause of the production of wheat throughout much of its extent since it desired that particular cereal for bread. It also affected nature in the pursuit of the circus: North Africa and Asia Minor for example were depleted almost entirely of their lion populations in order to obtain animals for these spectacles; Scotland contributed a bear to one such festive occasion. Trade and discovery encouraged the transfer of species from one continent to another, so that European weeds became as familiar in the tropics as potatoes in industrial cities of northern Europe. This process started as early as the spread of Neolithic crops from the Levant to Western Europe but received enormous impetus during the 16th century conquests by European powers and again in the 19th century's age of empire. The latter, for instance, brought about great ecological similarities in the tropics when different ecosystems were converted to the ubiquitous plantation producing rubber or plant oil.

In today's environments, there are effects in the type of food production encouraged by the Green Revolution and its successor developments. Large amounts of fertilizers, biocides and water produce a uniformity of production methods, which the more firmly installed by the conditions of uniform produce demanded by industrial-nation supermarkets. The general uniformity of several kinds of tourist destinations (is this fenced-off and guarded resort hotel in Thailand, Kenya or the Caribbean?) is another outcome of the globalizing forces. World-wide, the International Monetary Fund (IMF) is the institution which most produces this uniformity since it enforces the conception that every region must do what it does best without regard to local culture or the carbon-loadings brought about by export-oriented economies.

The way in which the application of natural sciences seem most likely to bind globally is via biotechnology, in which genetic uniformity is the most strongly aligned to the demands of world commerce. Such as dictated by global trade organisations and development institutions with their you must do a lot of what you do best [as we judge it]' policies, following the lead of international agencies. The reduction in the genetic diversity of crop plants during the 20th century as a result of commercial pressures to home in on one or two varieties or strains is well known. In that light, the advent of cloning from a single cell, as happened with a sheep in 1997, seems a logical development and full of business potential. It seems unlikely that it will produce a higher biodiversity in the world outside the laboratory, unless by some chance its search for genetic resources allies it to the conservationist movement.

IMPROVISATION AS A VIRTUE

The sociologist Niklas Luhmann (1989) points out that humans cannot communicate directly with the non-human world via speech. Though some New Age enthusiasts would dispute the assertion, most people in the Western world would, after a brief but regretful pause, agree. Luhmann suggests that in fact we talk to each other about the environment and since it is such a complex set of discourses, the discussions are separated out into a set of specialized channels in each of which there is resonance. Each of these channels corresponds to some recognised organizational conduit through which a discussion can flow. Thus we can have environmental economics, law, sociology, politics, religion, education, poetry, music, each containing a set of resonances about what is essentially the same thing but which has been represented in different ways.

One more important cultural facet can be added: in the West there has long been a tendency to dualism. Thus in each channel, the thrust is towards a 0/1 dichotomy: legal/illegal, relative/absolute, scientific/nonscientific, economic/uneconomic, and in the last analysis, good/evil. Again relating to much earlier histories, there is the concomitant likelihood that the 1' state will be Us and the 0' state, the Other. Thus one outcome of attempts to represent the complexity of human–environment relations is a series of separations of both fact (in the sense of the facts of politics, economics and law, for example) and value in the connotation of what is acceptable and what is not. An appealing image for this analysis is that of the pipe-organ. Looking at an organ case, we see a number of pipes of different length which each sounds only one note but which can be on or off: the correspondence to Luhmann's idea of resonances is quite strong. In some organ cases, the pipes are grouped rather as our approach to knowledge is clustered: the sciences, the social sciences, humanities and similar groups. Pursuing the analogy, we remember that the instrument can be played to an exact score as laid down by a composer, or the player may improvise.

Another image that could be helpful is that of the DNA (Di-ribo Nucleic Acid) molecule. Models show a double helix with the strands linked by base pairs. One strand could represent the actual changes in the world and the other our ideas about those transformations. The base pairs then look like the ways in which information about the one is transferred to the other. Some of the pairs will embody the best possible information flow whereas others will necessarily be fragmented or distorted. We can imagine a state in which information about an environmental process is not collected because it is too expensive or where known data are concealed because of the effect they might have on a company's share value. The model could be taken further to suggest the increasing magnitude of the interactions by widening the gyre of the helix and by colouring the strands to show the historic sequence. One problem is that it gives, as do tabular constructions, an air of inevitability: the possibility of contingent change looks unlikely. On the other hand, a creative piece of computer graphics might encompass all these aspects in a way several thousand words cannot.

TRENDS IN ENVIRONMENTAL HISTORIOGRAPHY

The historian William Cronon (1992) has remarked that we have had studies of ecology and economy, or studies of nature, but too rarely have we had all three together. Apart from the actual difficulties of bringing into one focus the different kinds of information provided in such approaches, there is perhaps the point that environmental history has tended to be directed towards certain ends. There are many examples of histories, which are prophetic in the sense of being warnings against a future, which is either inevitable or avoidable by prompt action. In Classical Greece, for instance, the Epicureans thought that the land was senile, overpopulated and that generally both it and the population had declined in their capabilities since an earlier Golden Age when all was in an optimal condition. In the period from 1965 onwards, roughly, there has been a plethora of books on environment, which have traced trajectories of the decline of nature and the rise of overpopulation and pollution. Almost every period in recorded history has been seen as the turning point towards perdition: the Ancient World's eventual materialism, the desacralization of Medieval Europe, the anthropocentrism of the Renaissance, the mechanical model of the world of Newtonian physics as adopted enthusiastically by the industrial revolution, the relativism thought to be made possible by the discoveries of uncertainties of quantum mechanics in the 1920s, and the triumph of capitalism inherent in the fall of the Berlin Wall, have all been seen as signal events and processes on the way to hell. Some histories indeed suggest that a short but pyrotechnic existence is the evolutionary fate of the human species and that we might as well have a hell of a good party even if we are sick in the bushes afterwards.

Within such over-riding themes, shorter periods attract more diverse agendas. In an era of the discovery of the ills of colonialism, the adverse environmental effects of imperial foresters, farmers and white hunters are bound to attract attention though some counterbalance has been offered by the role of colonial scientists in their prescient studies of the relation of rainfall, land use and environmental stabilities. Then again, reaction against some particular aspect of the present is often seminal. In the United Kingdom, the urban sprawl of the 1920s and 1930s reinforced myths about the rural idyll of (especially) the English village and provoked books, poetry and paintings that implanted the more acceptable faces of the pre-1914 landscape in people's minds as the desirable piece of heritage that might have to be fought for. It was not the images of industrial Halifax, or bungaloid Peacehaven that were supposed to inspire Tommy in his trench in Flanders or his tank outside Tobruk, but the combination of thatched cottage, medieval church and friendly pub. In the race for the tourist dollar and yen, the environment of Scotland is a powerful adjunct, no matter that much of it results from centuries of over-exploitation by rich landlords eager for profits from timber, sheep and deer or that the tartan cult is a 19th century invention by an English cloth maker with some spare capacity and an eye for the purchasing power of the military.

Romanticism, on the other hand, was largely provoked by the valuation of the individual over the mass. While it often attracted environmental icing (such as Wordsworth's anathema to the coming of the railways to the Lake District), it

is linkable to changes in the natural world only indirectly: by the growth of human population numbers, possibly. Yet the break with previous attitudes was absolutely critical in the revaluation of for example the mountain and other wild landscapes of Europe and North America, with incalculable consequences for the founding and management of national parks and for the rise of tourism. So the writing of environment history is bound to look out for examples of contingent turning points of an analogous character and the present time of turmoil of thinking and opinion-forming can thus be posited as a turning point from the pre-existing era governed by the machine metaphor to another phase, for which the appropriate language has not been born, but which will share in the renewed valuation of emotion, community and communication: a sort of environmental post-Diana syndrome.

ABANDONING BALANCE

The death in 1997 of the historian of ideas Isaiah Berlin recalls the relevance of some of his thought. He notes that the attainment of Utopias is usually accompanied by coercion on a large scale. The techno-centrics are accused of many sins in their exploitation of primary resources in developing countries, for example; the eco-centrics are labelled eco-fascists and associated with unsavoury regimes that were practitioners of some ecologically acceptable ideas. So Berlin (1991) would not favour the provision of a score with a de nite end in view; rather he is with the improvisers. He also reminds us of the relevance of the fragment of the Greek Archilochus, The fox knows many things, the hedgehog knows one big thing , for it is the Utopians that know one big thing and they are usually prepared to convert everybody to their point of view, like it or not. In our present context, then, Berlin s words seem germane. He suggests that a

> ••• perfect solution is, not merely in practice, but in principle, impossible in human affairs, and any determined attempt to produce it is likely to lead to suffering, disillusionment and failure.

Among other reasons, this is because there are incommensurables to be dealt with, there are choices between paths of equal good, and indeed some ultimate values may be incompatible with one another, then,

> ••• the best that one can do is to try and promote some kind of equilibrium, necessarily unstable, between the different aspirations of differing groups of human beings ••• [this] ••• is not a passionate battle-cry to inspire men to sacri ce and martyrdom and heroic feats. Yet if it were adopted, it might yet prevent mutual destruction, and, in the end, preserve the world.

The phrase crooked timber is from Immanuel Kant, who observed that out of the crooked timber of humanity no straight thing was ever made and in this context, no straight thing has ever been made nor is it worth trying. Fudge, muddle, crabwise-movement and indeed improvisation are the ways in which most attempts to construct a *modus vivendi* are made and which produce the greatest and most lasting successes.

This raises the dif cult issue of the relation between *pluralism* and *relativism*. Many thinkers might agree that the independence of the non-human world imposes in the end some limits, as does the nite nature of the capabilities of the human organism, as indeed do the empirical possibilities of human organisation. Further, to echo Kierkegaard, relativism is possible for history but is much more dif cult in making decisions for the future (Lukes, 1998). There are, naturally, notional confrontations which we may be asked to consider, which are too far removed from the everyday to matter to us as individuals, though they may matter a great deal to others. Then there are real options, in which, as Manuel Castells (1998) exhorts:

> ••• liberation is for people to free themselves from uncritical adherence to theoretical or ideological schemes, to construct their practice on the basis of their experience, while using whatever information or analysis is available to them, from a variety of sources.

In this we can recognise not only the need for pluralism but also that analysis may include the best moral judgement that a shared, locally felt, democracy can produce. No place for Utopia, therefore; neither for existential hand-wringing. So organists need to follow J S Bach all the way: they need to be able to understand the scores and to leave some of them behind as inspiration for those to follow but the real genius is shown in the quality of the improvisations (*see* **Virtual Environments**, Volume 5).

Globalization in Historical Perspective

JOHN H BODLEY

Washington State University, Pullman, WA, USA

Globalization can be understood as a cultural process in which peoples, cultures, natural resources, and ecosystems from throughout the world are drawn into a single, vast, elite-directed network of production and consumption. Such a network was certainly in place by 1600, but its human and cultural roots lie much deeper. From a broad historical perspective, globalization is a scale phenomenon in which growth occurs in great waves up to the limits set by particular cultural organizational structures, in particular social and natural environments. When a growth threshold is reached, either some form of perhaps cyclical equilibrium is established, or a breakthrough beyond the limit is achieved to a larger scale. Another cultural transformation must take place before another growth wave can occur, and so on. Globalization is simply the most recent phase of a humanly driven cultural process designed to increase the scale of culture. The principal outcome of this growth process is greater concentration of social power. This growth process is fundamentally different from biological evolution, which is concerned with species-level survival, and may not be directed toward a goal of greater organizational scale and complexity.

THEORETICAL PRELUDE

Globalization resembles earlier cultural transformations, but it has produced a profoundly different cultural world because of the absolute quantities of people, energy flow, and materials involved, and the distinctive cultural institutions that globalization requires. The historical evidence suggests that beyond a certain minimum scale, cultural growth naturally becomes an elite-directed process that disproportionately benefits the elite and shifts costs to the majority. This makes growth a difficult process to sustain, because elite decision-makers who enjoy increased benefits, but are relatively unaffected by increased costs, have little incentive to accept natural or cultural limits. As used here, *scale* refers to the absolute size of population, economic values, or any quantitative variable related to human well-being. *Culture scale* refers to specific order of magnitude differences in the size of social systems, and the corresponding cultural features that support them. The theory is that scale-increases occur as an elite-directed process designed to disproportionately concentrate social power under elite control. In this respect, *big* may not be better for everyone, but small economies may be beautiful as Schumacher (1973) has observed.

Scale theory, by emphasizing the role of human decision-making and decision-makers, addresses the theoretical shortcomings of orthodox cultural evolutionary theory, and offers a more useful way to understand globalization. Evolutionary, historical, or sociological explanations of cultural development that take society as the unit that adapts itself under the influence of natural selection are theoretically unsatisfactory, because such explanations make the growth process appear both natural and inevitable. These approaches also tend to ignore, or obscure, the role of human decision-making agents, and the differential distribution of the costs and benefits of growth. Scale theory takes individuals and households as the active, decision-making units, and treats socially expressed culture, ideology, technology, and institutions as the means, or survival vehicles used by particular human agents to achieve their objectives and improve their life chances . This assumes that humans are primarily driven to survive and reproduce, and to ensure that their children will be able to do the same. In support of this primary biological objective, individuals may have an innate, although variable disposition to dominate and exploit others whenever possible, and they will seek to minimize their own effort by getting others to work for them. However, the existing institutional structure of culture sets limits on competitive striving by individual decision-makers.

Scale theory is theoretically related to the evolutionary materialism approach outlined by sociologist Stephen Sanderson (1990, 1999), and the concept of dynamic materialism developed by economic historian Graeme Snooks (1996, 1997, 1998). The common assumption of these approaches is that globalization was not pre-ordained, is not

inevitable, and is perhaps not even an adaptive, or beneficial process for humanity as a whole, in contrast to the claims of orthodox evolutionary theory, and many current advocates of globalization. Robert Wright (2000) for example, claims that globalization is the product of natural cooperation, not competitive struggle.

It is inappropriate to apply a purely biological model of evolution to cultural development because culture and cultural information are transmitted much more easily than genes. Culture change is an intentionally-directed process, that occurs through purposeful invention, diffusion, and/or imitation, rather than through random mutation and natural selection. However, because human genes and culture affect each other, it is more accurate to acknowledge that human development is a co-evolutionary process involving both culture and biology (Boyd and Richerson, 1985). Furthermore, civilizations do not reproduce and multiply, rather, they have historically grown larger and fewer. Carneiro (1978) and Naroll (1967) graphically demonstrate the long-run decline in the number of polities in the world, and Taagepera (1978a,b, 1997) shows how they have increased in territorial size. Civilizations may appear to compete with other civilizations as systems, but their human leaders are the actual competing units. When evolutionary success is measured by either adaptability or reproductive success, civilizations fare poorly as evolving organisms , because their diversity, numbers, and longevity decline over time. Culture itself was the key to human adaptive success, but the growth of human cultural *systems* has been curiously maladaptive for humanity as a whole because it has reduced cultural diversity, made patently less-sustainable cultures dominant, and actually increased the absolute number of people living under suboptimum physical conditions.

GLOBALIZATION AND SCALE THEORY

If globalization is fundamentally a scale phenomenon, it is important to consider the physical significance of size. The scale of human society and culture is important theoretically because it is related to four crucial variables:

1. the level and distribution of household well-being, standard of living, or human costs and benefits;
2. the distribution of decision-making power;
3. the institutional complexity and technological organization of society;
4. the trajectory of growth and the dynamics of change.

Scale-increase is a disruptive, increasingly expensive process that changes all of these variables, and disturbs pre-existing equilibria. It is difficult to imagine why natural selection would ever favor growth in the scale of society and culture in general, or the development of a global-scale culture in particular. Size is a crucial variable in nature, where large things are understandably rare. Small animals can survive on fewer resources than large animals. They reproduce more rapidly, recover more quickly, and can adapt to change more easily than larger animals. This may be the reason why bacteria are the most successful organisms on earth and perhaps in the universe, considering total number of individuals, diversity of species, total biomass, and overall adaptability as the measure of success. Likewise, people living in small cultures can respond more quickly to environmental changes, and can make decisions more democratically than people in larger societies. Energy-intensive communications and transportation technology make it possible for global-scale societies to respond quickly to environmental crises, but bureaucracy and power inequalities bias such response. Because of their relative social equality, people in smaller societies are more able to share the benefits of their success. Scale itself may be the most important variable, because basic human nature can be assumed to be a constant.

The physical laws of gravity, and geometry mean that growth is an allometric process, in which internal relationships change disproportionately. For example, surface area increases geometrically by the square of length, and volume and mass increase by the cube of length. These principles also apply to cultural growth and development, and especially to globalization. The most critical disproportion for human societies is in the distribution of social power and decision-making abilities. Social power naturally becomes disproportionately concentrated in the elite as societies grow larger, unless specific cultural countermeasures are applied by the majority. This helps explain why cultural growth occurs, and calls attention to who directs change, and who most benefits from it.

Like biological organisms, the size and form of human societies occur within relatively narrow ranges determined by thresholds set by physical laws and the functional limits of culture. The population of autonomous small-scale, domestically organized prehistoric societies averaged only 500 people, and typically ranged within magnitudes of under a threshold of 10^3 (1–9 thousands), although there were much larger tribal world systems. Pre-modern politically-organized city-states, and agrarian empires did not normally exceed population magnitudes of 10^7 (10–99 millions), also organized into agrarian world systems. Commercial organization produced a global economic world system that is unlikely to ever exceed a magnitude of 10^{10} (10–99 billions).

Human settlements also display remarkable, mathematically-predictable scale regularities. For example Roland Fletcher (1995, 71–81) found that settlement size appears to be limited by the increasing difficulty of interpersonal communication and the stress of interaction that can only be overcome by organizational, technological, or design changes. The interactions amongst people in

a settlement increase exponentially as population grows, such that a 10-fold increase in population would theoretically produce a 100-fold increase in potential interaction. Domestically organized villages typically remain below a threshold of 200–500 persons.

The urbanization process, or the transformation of villages into cities, was the first crucial step toward globalization. Cities have always been at the center of socio–cultural transformation and economic growth. Urbanization began when power-seeking elites successfully developed new political and economic institutions to overcome the limits to societal growth that maintained domestic-scale villages in equilibrium. Fletcher (1995, 82–90) concludes that the total area of urban settlements, and the rate of urban growth are limited primarily by the technology of interpersonal communication. As cities grew larger, commercial exchange became a virtual necessity, because political power can only effectively command tribute payment within relatively narrow limits. The earliest cities became possible, some 6000 years ago, with the development of bureaucratic political organization, supported by writing, or its functional equivalent. These cultural changes permitted a 100-fold increase in the area of the earliest cities, above the area of pre-literate, domestically organized villages, and a 1000-fold increase in areal growth rate.

Andre Gunder Frank (1990, 1991) and Gills and Frank (1991) argue that globalization is the culmination of a growth process that began with the world system some 5000 years ago based on the earliest Mesopotamian city-states. The first cities of 25–45 000 people required lengthy and expensive exchange networks, and imply the existence of at least a regional world trade system for their material support. Five thousand years of continuous growth in this world system required massive transformations in cultural organization and technology. Cities of 100 000 people or more, which appeared by perhaps 500 BC, required monetary systems, and the large-scale commercialization of food systems which ultimately prepared the way for the capitalism world system. During the 4000 years up to 1500 AD, the number of such large cities in the world steadily increased from perhaps 8 in 2000 BC to 75 by 1500 AD. Their average population size increased from 30 000 to 100 000 people, with the largest over 500 000. By 1500 AD the total number of people living in such cities may have exceeded 7 million people (Chandler, 1987; Sanderson, 1999, 112; Wilkinson, 1992, 1993), and would have required the vast exchange system that became the modern global-scale world system. This new world economy initially grew out of a European foundation between 1450 and 1640, and became a truly global-scale world system by 1815 (Wallerstein, 1974). Globalization is an urban-centered phenomenon. Since approximately 1850, the development of fossil fuels, railroads, electronic communication, mechanized printing, and the emergence of large-scale corporate businesses permitted a 100-fold scale increase in the size of cities beyond the previous threshold of 100 km^2 and 10 million people, and a 1000-fold increase in urban growth rates.

THE DYNAMICS OF CULTURE SCALE

During the past million years proto-humans and humans have experienced eight great transformative waves of cultural development (Table 1), each producing societies of successively larger scale, and a larger global population. In this development process, the dynamics of culture change itself changed, becoming more rapid, and more narrowly directed. Globalization is only the most recent such transformation. The first transformation may have been completed 100 000 years ago. This coincided with the appearance of physically modern humans, and fully human culture based on shared, socially-transmitted, symbolic information, and speech. The second transformation beginning perhaps as early as 50 000 years ago saw the development of highly efficient foraging technology which allowed people to occupy virtually the entire globe. Growth to the limits of efficient foraging produced an equilibrium world of perhaps 10 million people, with leadership widely dispersed. The third transformation was the change from mobile to settled village life based on domesticated plants and animals during the Neolithic, which began at the end of the Pleistocene 10–15 000 years ago. The Neolithic wave produced a world of tribal villagers with perhaps 85 million people.

Cultures can be grouped into three broad-scale types according to whether social power is organized domestically, politically, or commercially. Social power is the way individuals and households secure the material, social, and cultural resources that they need to maintain themselves and successfully reproduce. It is assumed that everyone is naturally driven to seek social power, although the specific form that power may take is an important cultural variable. When social power was domestically organized, all households

Table 1 Great cultural transformations

Domestic scale cultures
Hominoids • Humans, 100 000 BP
Humans • Forager cultures, 50 000 BP (speech, art)
Foragers • Village farmers, 10 000 BP (domestication)
Political scale cultures
Villages • Chiefdoms, 8000 BP
Chiefdoms • Agrarian civilizations, 6000 BP (urbanization)
Commercial scale cultures
Agrarian civilizations • mercantile capitalism, 1450 AD
Mercantile capitalism • industrial capitalism, 1800 AD
Industrial capitalism • financial capitalism, 1900 AD

had relatively equal access to crucial resources, and there was no incentive for growth in either the scale of society or economic productivity. Domestic cultures displayed demographic equilibria in general balances with their resources that could be measured in millennia. However, they were not totally static. It is a striking fact that most important domestic technologies including weaving, ceramics, and domestication were produced in domestically organized societies, and the benefits were universally distributed.

An important cultural organization and scale line was crossed some 8000 years ago, when the first aspiring power elites succeeded in transforming the characteristically weak, temporary, and informal village *headman* position into the coercive political of ce of *chief* that could be transmitted cross-generationally within a ranked descent line system. In this *politicization* process, village chiefs were then able to extend political power over more than a single village, producing simple, and then larger, and more complex chiefdoms that encompassed thousands of people. As soon as it became possible for individuals to consolidate their power gains, and transmit them to their children, the move up the scale to city-states, kingdoms, and agrarian empires occurred relatively quickly. The key difference between this kind of elite-directed transformation, and the previous domestically directed developments, is that the bene ts and costs were not equally shared. In this respect the politicization process is not fundamentally different from the contemporary commercial globalization process. Under politicization, elites assume life or death power over commoners, and extract surplus energy from them, treating them much like domesticated animals. Elites enjoy superior life chances, because they control vast material surpluses and can insulate themselves from natural shortages. Elites live in larger, more secure residences, and they surround themselves with domestic servants, and multiple wives and concubines. The scale of elite power corresponds directly with the scale of society, thus producing a natural incentive for elites to promote further growth. Commoners must feed themselves, pay taxes, ght wars, suffer famines, and become human sacri ces, either in temples, royal tombs, or on battle elds. Elite-directed cultural developments such as urbanization, intensive agriculture, monumental architecture, monotheism, writing, and military technology are designed to support political power and exclude non-elites.

How this great political transformation occurred cannot be fully explained, but power-seeking individuals had to overcome the limits that the majority placed on their leaders. It is likely that this occurred when the majority was forced to choose among the lesser of evils under crisis conditions. One of the paradoxes of large-scale, politically-organized societies is that they are conspicuously unstable. Social inequality and continuous expansion are dif cult and costly to sustain using political power. Ancient agrarian civilizations displayed a persistent pattern of growth and collapse, with a long-term trend toward increasing total area, population, and urbanization. Equilibrium was an exception, and few civilizations lasted more than 130 years, and only rarely did they exceed 300 years (Taagpera, 1997). The threshold for politically-organized empires was probably reached by the British Empire which brie y controlled one-quarter of the world s population and land area. Growth beyond that level called for a different form of organization, and this requirement was met by an expansion of commercial enterprises.

THE CAPITALIST ROOTS OF GLOBALIZATION

Globalization is a cultural process in which economic elites use commercial exchanges to create a supra-national, global-scale social system, a world-economy , that operates without a single centralized political power. As Wallerstein (1974) observes, an economically-based world system makes possible a much larger, more ef cient, and apparently more resilient system than could be integrated into a world-empire by political power alone. Globalization was created by the great cultural transformation that accompanied the rise of capitalism in Europe. Thus, capitalism itself is the key to understanding globalization. There have been many formal de nitions of capitalism, but its most critical feature is that it supports the rise to dominant decision-making power of commercial elites, who are able to concentrate social power by co-opting, and at times even directing the politicization process in order to promote their commercial projects. Capital is social power, whether in the form of nance capital, xed capital in buildings, equipment, and inventory, or land. Capital accumulation, rather than consumption, is the primary objective of a capitalist economy. Under capitalism, the commercial elite is dominant, but political rulers may sometimes also take a direct entrepreneurial role. Rulers support and defend commercial activities, they supply crucial infrastructure, and help to maintain and develop human capital by supporting public education, health, and welfare. The capitalist commercial elites are politically free to develop new institutions and organizational forms that allow them to accumulate capital by commercial business enterprises.

The minimal formal elements of capitalism include developed markets for land, labor, and money. In classical Marxist terms, capitalism can be readily de ned as an economic system in which money is primarily exchanged for commodities, which are in turn exchanged for more money. This is production for commercial exchange, rather than for domestic consumption, or use value. The dominant purpose of exchange is to obtain a monetary pro t. The social structure of capitalism is distinctly unequal. Adam Smith (1776) described this inequality as *specialization*, or a division of labor between landlords, manufacturers, and laborers,

arguing that laborers naturally needed masters. When viewed as a total economy (Snooks, 1994), a national capitalist economy has three sectors, with a household economy at the center, which produces, maintains, and allocates labor, and receives wages, salaries, interest, and goods and services from the private commercial sector and from the public, or political sector. The national economy is not a closed system, but gives and receives economic flows to and from other national economies. The basic organizational elements of capitalism include a world-economy with a geographic and hierarchical functional division of labor, and with strong national states at the core. The global hierarchy is expressed as an unequal international distribution of costs and benefits in which the holders of capital are rewarded more generously than those who have only their labor to exchange. Maldistribution of power thus seems to be an intrinsic feature of this system, especially in the absence of a strong world-empire government.

A long-running intellectual debate over the origins of capitalism and globalization concerns the relative importance of ideological factors versus material conditions. Anthropologist Marshall Sahlins (1996) places capitalism within a broader European cosmology that views people as naturally evil and selfish. From this perspective, economic scarcity is also a natural and perpetual human condition, and it is a given that societies are controlled by hierarchical power structures and coercive governments. These ideas are sustained by the salutary beliefs that everyone will benefit from economic growth driven by free market capitalism. These fundamental beliefs also explain the quest for increased social power and technological progress, which are thought to be natural and inevitable.

Many anthropologists are cultural materialists, arguing that economic practices are primarily determined by material conditions. However they acknowledge that cultural ideas, or beliefs, are an important part of human motivation. The beliefs underlying capitalism can be treated as the *ideological* causes of globalization, because they rationalize the cultural transformations that produces globalization. From a materialist and a scale perspective, elite power-seeking is the primary motivation for globalization. However, the opportunities for power-seeking are limited by both environmental and cultural conditions as shaped by historical circumstance. Diverse belief systems can be mobilized to rationalize many different power-seeking strategies, and in that respect must be considered secondary to the personal motivation of power-seeking. To some extent, globalization was a consumer-driven process, but consumer demand is highly constrained by the cultural organization of power, political economy, and political ecology. Globalization was also not just a product of the market economy or monetization, because for millennia organized markets and money have linked villages, towns, and cities in all the major civilizations. However, local markets have primarily traded in domestic staples, and benefited society as a whole. It was long-distance trade in luxury goods for the elite that made it possible for merchants to take advantage of profit-producing price differentials and offered the initial step toward globalization.

THE EUROPEAN ORIGINS OF GLOBALIZATION

In order to explain the origins of the modern capitalist world, social scientists at first focused on European science, exploration, and technology. Initially, they considered the Industrial Revolution to be the principal architect of material progress. However, 20th century historians demonstrated that capitalism preceded industrialization by centuries, and they argued that the long-term process of capital accumulation gradually produced widespread improvement in human welfare. For example, Snooks (1993, 4) ecstatically proclaimed that industrial growth since 1750, ••• massively shifted the distribution of income in favor of the lower socioeconomic classes . At the same time many postmodern anthropologists argued that the commodities that were at the heart of globalization could be understood by their culturally unique symbolic meanings for individual consumers, and their use in the construction of individual self-identity (McCracken, 1988; Miller, 1987). Some even described commercialization as a democratic process in which markets, commodities, consumption patterns, and their cultural meanings came to be mutually constructed by marketers and consumers. Like earlier theories of cultural evolution, these postmodern interpretive approaches make capitalism and globalization seem both natural and inevitable, and avoid crucial issues of the distribution of material benefits and social power.

The capitalist global system was developed by merchants and investors centered successively in Venice, Antwerp, Genoa, Amsterdam, London, and New York. A growing number of elites in these urban trade centers enjoyed ever-higher living standards and consumption levels, whereas wageworkers, serfs, or slaves gained little control over the conditions of daily life. Many Europeans did experience some improvements over the depressed living conditions and chronic insecurity they had experienced under feudalism.

The economic elites who created the modern world system were responding to a historically unique set of circumstances. The crisis of feudalism from 1230–1400 that peaked in 1350 was the immediate precursor of the push for European commercial expansion overseas. This prolonged crisis was an unfortunate conjunction of bad weather, and overpopulation produced by gross inequality and over-consumption by the nobility. This situation created a century of hyperinflation, peasant rebellions, wars between the nobility, famine, and disease. The nobility

raised rents to stay ahead of inflation, but the less fortunate majority saw their absolute wages decline. The political and economic turmoil made it advantageous for the merchant and political elite, who were the only people capable of strategic economic planning, to turn to more capital-intensive technology, seek foreign resources, and invest in mercantile capitalism. Furthermore, the existence of autonomous market towns under the politically decentralized European feudal system created an obvious opening for enterprising merchants to expand their power (Sanderson, 1999). Economic crises spurred the growth of financial capital because it forced governments to borrow from private lenders. Another round of inflation and turmoil from 1470–1610 corresponded with the beginnings of long-distance overseas expansion, which was followed quickly by the establishment of the Bank of England in 1694, and the London stock exchange in 1697.

Historian Fernand Braudel (1977) argued that successful commercial families were able to manipulate political and economic power within very hierarchical, but not totally closed European societies. A key element in their success was that they managed to transmit and accumulate their economic power across generations. Capital accumulation by a few households in an intensely competitive cultural environment confers a decisive advantage to the successful, as Snooks (1998) has observed. Accumulation would not be advantageous in a culture that distributed resources equitably. The fact that the European population had recovered from the 14th century devastation of plague and war by 1650, and began a long upward curve of exponential growth by 1800, suggests that most people were gaining some material benefits from capitalism and globalization. Many ordinary households intensified their labor, producing more for the market, and engaging in wage labor as opportunities arose in the expanding cities. In this respect Europeans of all social strata participated in globalization, and benefited from it to some degree. However, very few were able to accumulate investment capital and secure economic independence.

Some historians suggest that a consumer revolution or a democratization of consumption began in England and America as early the 18th century, and regard this as the first appearance of mass consumption (McKendrick *et al.*, 1982). Such an outcome would be evidence for a widely shared benefit of globalization. However, even long after the beginning of globalization, living standards remained extremely inequitably distributed, and the benefits of higher consumption levels spread very slowly. Consumption by the relatively powerless poor in the vast lower class was limited to the necessities of food and domestic durables. The shopkeepers, merchants, and professionals in the small middle class, could afford the comforts and decencies of house, groceries, bedding and tableware. The costly luxuries of the leisured lifestyle were reserved for the handful of households in the upper gentry and aristocracy, who engaged actively in competitive emulation. As the global trade network of mercantile capitalism developed, newly imported commodities were generally consumed first as luxuries by those in the highest social ranks, and were then very gradually diffused to the lower classes. By the 1680s, English merchants were importing different colors and qualities of cloth to appeal to specific social ranks, and giving out free samples to the nobility, hoping to both promote and profit from competitive emulation. The earliest imported consumer goods to become objects of mass consumption in England were pepper and dried fruit by 1559, tobacco by 1650, sugar by 1690, and tea by 1730 (Shammas, 1990, 1993). Wills (1992) stresses that new consumer markets did not just happen. They were created by intense competition between rival international trade monopolies.

Theodore Rabb (1967) provides an excellent picture of the initiators and prime beneficiaries of globalization who were centered in London between 1575 and 1630. In a given year, probably only 2500 individual investors owned the 33 joint-stock companies that actually funded and directed England's mercantile-capitalism overseas expansion and thereby transformed the world. These economic elites represented no more than 0.25% of all households in the kingdom of some 5 million people. Three quarters of these investors were wealthy merchants who picked the only route open to them for material advancement, given their non-aristocratic social position. Only one quarter of the investors were drawn from the hereditary landed aristocracy, who represented the top 2% of the social hierarchy. Historian Lawrence Stone (1965, 1973) shows that the aristocrats were diversifying their investments in order to maintain their privileged social status which was threatened by the unsettled conditions accompanying the collapse of feudalism.

European economic growth was certainly boosted by the 10-fold increase in the existing stock of gold and silver represented by imports to Europe between 1500 and 1680. The degree to which bullion was narrowly controlled is a truly astounding reflection of the elite domination of the emerging global system as a whole. At this time, the Spanish hub of the New World silver trade was in Mexico city, where in an average year a mere 44 large investors handled more than 60% of total cargo value in trans-Atlantic commerce (Hoberman, 1991). The largest English development enterprise of the era, after privateering, was the British East India Company, which was founded in 1600. The East India Company proved to be an excellent investment. Seven of its trading expeditions conducted from 1601–1612 produced an average annual income of £132 for each investor. In England at that time 98% of households lived on less than £120 a year. Of course many of the larger investors owned shares in several different companies, and

also received rents and other income. According to Gregory King's (1936) careful estimates, by 1688 some 2000 large merchant traders were earning £400 a year, putting them economically almost equal with knights and esquires in the gentry class (King, 1936). Exploitation of low wage workers, slavery, trade monopolies, and privateering produced very high rates of returns on investments, but the very highest returns were enjoyed by aristocrats at the highest level of government who supplemented their investments with royal favors, bribes, and abuse of public office (Stone, 1973, 3–15). A few very high incomes undoubtedly accounted for much of the economic growth during this period, and not all was invested in further growth. Between 1600 and 1688 the total wealth of England more than tripled, and much of the new wealth financed a frenzy of luxury building and consumption by the elite.

AGRARIAN TRANSFORMATION AND LONDON POVERTY, AD 1500–1700

The initial development of the modern world economic system is mirrored in the transformation of the English agrarian system between 1500 and 1700 AD This transformation was carried out simultaneously with overseas expansion, and was directed and financed by many of the same few individual investors. The commercialization of grain removed a feudally-organized agrarian food system in which a land-owning aristocracy extracted surplus grain from a peasantry that was largely self-provisioning. At least 15 regional grain markets had emerged by 1500, and some 800 small towns grew up around local marketplaces. Similar conditions and transport factors meant that grain could be sold at the same price in each distinct market region (Gras, 1915). Even though local farmers could sell in any market town, the regional markets remained relatively isolated. Few specialist merchants were able to take advantage of price differentials in different markets. Local municipal authorities imposed numerous regulations on grain handling and marketing, all apparently designed to protect the consumer from price manipulations, poor quality, or dishonest measures. Middlemen grain traders, or wholesalers were regarded with suspicion, and widely assumed to be disreputable.

The city of London's population grew 10-fold between 1500 and 1700, as the city became the center of the expanding global economy. This order of magnitude population growth soon overwhelmed Britain's medieval system of local and regional grain distribution. In 1250 London drew on a local grain market within a radius of 40 km, but by 1500 the city had grown to some 50 000 people, and the local market proved totally inadequate. London needed a much larger distribution system that could draw from all over England. In response, the volume of coastal grain shipments increased 10-fold between 1580 and 1680, and a single national market emerged. After 1500 imported grain became increasingly important in the London market. Previously, the foreign grain trade was handled by foreign merchants, and largely in response to famines. The grain supply was so problematic that from 1514 to 1678 London's municipal authorities bought and sold grain, established public granaries, and urged the guilds to buy and store grain for resale to consumers at reasonable prices during shortages. By 1700, London grain merchants were trading with Scandinavia, central Europe, Holland, Spain, the Caribbean, New England, Virginia, and Canada. As scale theory would predict, the new global food market disproportionately benefited a few very large merchants. Just four merchants handled half of London's wheat export business during three trading seasons between 1676 and 1683 (Gras, 1915, 197).

London's population reached a phenomenal 700 000 people in 1700, and the most devastating plagues and famines seemed to be over. Most of the national population was no longer in control of their food distribution system, and with the large land-holders fencing off the open fields that the peasants had used for subsistence, and converting them to pastoral use, most rural households were also losing control over food *production*. Most foodstuffs, including grains, had become commodities that everyone had to purchase with cash. England's national grain market was absorbed into a single global market. One could of course argue that the subsistence-level peasants ultimately benefited from these changes in the food system. However, no one should be forced to choose between rural, subsistence-level servitude, and urban poverty and wage-servitude. By the late 19th century conditions had clearly worsened for the majority. The New Domesday Book shows that 75% of the rural land in England and Wales in 1875 was held by just 14 000 large landholders, who represented a mere 0.28% of all households in a population now grown to 25 million people (Bateman, 1883). This was not an improvement over feudalism. 95% of households were left with less than 0.5% of all privately owned land. At the same time Charles Booth (1892–1903) found that 1.2 million people, more than 30% of London's population, were living in poverty as defined by inadequate income and crowded housing conditions. The 18 000 wealthy, upper class people represented the top 0.5%. These data suggest that the previous four centuries of economic progress increased the absolute number of poor in England, and left most people with less control over the conditions of their daily life.

INDUSTRIALIZATION AND URBANIZATION IN AMERICA, 1790–2000

Between 1790 and 1990 the American population increased 65-fold, and national income expanded an incredible 1000-fold. Even though America was widely perceived of as

a land of opportunity, the actual distribution of income and wealth changed little and remained very inequitable throughout this period. Vast areas of Native American land were opened for settlement, but much of this land was difficult and expensive to develop, or it was controlled by land speculators. Economic growth did produce a large middle class, but the absolute number of very poor also increased, whereas the elite became inconceivably powerful. The primary cultural changes from mercantile capitalism to industrial and financial capitalism that drove America's economic growth were reflected in changes in the agrarian system, much as in the earlier transition from feudalism to mercantile capitalism. In 1790 America was a rural nation in which 95% of the population lived on small, self-provisioning farms that produced limited marketable surpluses. By 1990 America was 75% urban, and agriculture was large-scale, capital-intensive, industrialized, and fully commercialized. This elite-directed cultural transformation was largely carried out within the space of four decades between 1850 and 1890, and clearly disadvantaged small-scale agricultural producers (Berry, 1977).

America's transformation required a series of massive changes in transportation, communication, production, distribution, and in the organization of business enterprise itself, that collectively expanded the speed and scale of commercial transactions (Chandler, 1977). The most important change was the creation of bureaucratically-organized, corporate businesses, that combined multi-unit enterprises and could amass capital and grow to a scale never before possible. Remarkably, few people actually financed and directed these changes. Historian Peter Hall (1973) argues that America's great national expansion was initiated in the 1850s by a tiny group of some 200 Boston families. These families were each worth at least $100 000 in 1848, owned 37% of the personal property in the city, and were the major shareholders in Boston's 50 largest banks and insurance companies (Pessen, 1973). At that time, Boston was a city of 137 000 people, much like London in 1580, and was the banking center for the entire country. The Boston elite accumulated trans-generational family fortunes from a mercantile base by investing prudently, marrying carefully, and forming dynastic trusts (Friedman, 1964; Marcus, 1992, 60–70; Farrell, 1993). According to Hall, these wealthy New Englanders financed the first great American business corporations, and used their philanthropy to create the elite private foundations and colleges, such as Harvard and Yale, that trained the professionals who then built the institutional and ideological infrastructure for a commercially focused, elite-directed American nation.

As America grew, the number of millionaire investors centered in Boston, New York, and Philadelphia expanded from an estimated 40 in 1860, to 2500 in 1870, and 3800 in 1897 (Soltow, 1975, 112–113; Beard and Beard, 1934, 383–384). At the same time more than half of the adult male population remained landless, in spite of the Homestead Act of 1862 and the westward expansion movement. By 1900 there were perhaps 1500 industrial corporations with capital assets of $1 million or more, directed by some 18 500 corporate board members and major stockholders (Roy, 1983). Collectively these 22 000 financiers and corporate directors formed an economic elite that represented less than 0.15% of American households in a nation of 76 million people. Their decisions to expand the scale and scope of commerce had transformed the nation and the world by the end of the 19th century.

After 1900 small farmers were steadily marginalized by the technological changes promoted by the land grant colleges, the Department of Agriculture, and the Extension Service which promoted the interests of the largest agricultural producers, in response to corporate interests (McConnell, 1953; Domhoff, 1996). These new institutional structures in combination with the railroads, financiers, farm machinery manufacturers, the petroleum and chemical industries, and mass-merchandisers account for the rapid dominance of the large-scale factory farm system. By 1987 the 100 largest corporate farms accounted for more than 10% of all agricultural production (Krebs, 1992, 28) and by 1992 14% of total farms accounted for 45% of all farm product sales (US Department of Commerce, 1996). This is the top-heavy agricultural model that was later promoted overseas as the Green Revolution, where it had the same marginalizing effect on small farmers.

By the 1920s New York City had become the center of the evolving modern world system. Europe's immigrant poor crowded into the slums of New York, where by 1900 some 2.3 million people, 70% of New York's population, were jammed into unsanitary tenements (DeForest and Veiller, 1903). America's commercial-elite had already accumulated the world's greatest concentration of economic power under the control of a few wealthy families, giant industrial corporations, and financial institutions. Many New York families, financiers, and corporate directors and their descendants played a leading role in creating the national and international institutional structures that produced a vast increase in the scale of the global economy. For example, John D Rockefeller's personal fortune of $200 million gave him enormous influence. However, financier J P Morgan's effective power was much greater. By 1912 Morgan exerted direct or indirect control over every sector of the national economy, with directorships or controlling interests in 34 large financial institutions, 10 insurance companies, 32 transportation systems, 12 public utilities, and 135 other corporations, with combined assets of $45 billion (Brandeis, 1914). In 1994, one individual directed five giant corporations with combined capital assets of $549 billion, and ten people directed 37 companies with combined assets of $2 trillion, representing nearly 10% of all corporate assets in the country (Bodley, 2000). In 1998

there were three executives who each controlled financial assets of more than a trillion dollars in the three largest Wall Street investment firms (Califano, 1998).

TRIBAL VICTIMS OF GLOBALIZATION, 1450–2000

The globalization process included several phases of colonialism in which peripheral and external areas were incorporated into the expanding world system. Millions died during the initial mercantile-capitalist phase from 1450–1800 when many of the world's great agrarian civilizations were brought under European domination. During the following industrial phase from 1800–1900, much of the rest of the world was added to the periphery of the world system. Europeans settled in the most favorable areas, and turned other peripheral areas into sources of raw materials and labor. However, dispersed colonies proved too costly and difficult to administer, and external colonialism came to a formal end in most of the world shortly after 1950. Internal colonial conquest continued throughout the 20th century until virtually all of the most isolated autonomous domestic-scale peoples and cultures were incorporated in the world system.

At the beginning of the Industrial Revolution, Japan had completed its independent transition to capitalism, but ancient civilizations still existed in China and Africa, and there were numerous traditional kingdoms and/or chiefdoms in India, the Middle East, and the Pacific. The great Western colonial powers claimed 55% of the world's land area, but exercised effective political control over only a third of the world (Clark, 1936, 5). Perhaps 200 million indigenous people, roughly 20% of the global population, still lived in autonomous and largely self-sufficient domestic-scale, tribal cultures, and still effectively controlled approximately half the world. Over the 150 years between 1800 and 1950 virtually all of this territory was conquered and incorporated into the world system in a process of internal colonialism in which as many as 50 million indigenous people may have died (Bodley, 1999a). Natural resources and labor flowed into the world system from these formerly external indigenously controlled territories. This final conquest produced a fully global modern world system, but at an enormous cost in ethnocide, genocide, and ecocide suffered by the peoples and territories that were forcibly incorporated.

The conquest and incorporation of indigenous people and territory not only destroyed the economic autonomy and political independence of millions of indigenous peoples, it also had a devastating demographic impact. Demographic disruption often initially took the form of drastic depopulation, when people were enslaved and killed by invaders, and when they died from newly introduced diseases to which they had little immunity. Many cultural groups that relied on fertility-limiting cultural practices to maintain low population densities were quickly exterminated by sudden increases in mortality. Many indigenous peoples died as a direct result of violence perpetrated by outsiders. Many governments organized military campaigns against tribes, and a few deliberately pursued genocidal policies in an effort to totally exterminate certain tribal groups. The largest loss of life probably resulted from the actions of individual colonists who acted on their own before governments established formal political control. Colonial governments sometimes intentionally left certain regions as uncontrolled frontiers, where their citizens were allowed to systematically kill and exploit tribal peoples. In areas where tribal people were not needed as labor, they were sometimes classified as non-human , and were killed with impunity. As early as 1837, under pressure from humanitarians, the British government officially acknowledged the human cost of colonialism in a lengthy Imperial Blue Book on aborigines (House of Commons, 1837), but the imperialism went unchallenged.

As soon as indigenous peoples lost control over their territories and subsistence resources, it often became impossible for them to remain economically self-sufficient. Depopulation also reduced the economic viability of tribal groups, but competition with colonists over resources, especially when the tribal land base was reduced by government decree, was often the decisive factor compelling native peoples to participate in the market economy, whether as wage laborers or cash croppers. There was also a desire to secure manufactured goods, such as metal tools and factory clothing. However, the desire for trade goods was usually not sufficient to force tribals into full-time, permanent participation in the market economy. As long as indigenous groups retained a viable subsistence economy, they were often poorly motivated target workers, and colonial administrators used special taxes and laws to force them into the market economy. Involvement in the market economy became a self-reinforcing cycle, because wage labor disrupted traditional subsistence activities, and cash-cropping depleted natural resources making self-sufficiency even more difficult. The problem for most indigenous people was that they were forced into the global system at the very lowest level, without the economic resources to operate effectively in a capitalist world, and without the political power to protect their interests. Where reservations were set up for conquered indigenous peoples, or treaties were negotiated, as in the United States, lands that were originally communally held were often converted to individual ownership and acquired by outsiders. Reserves were often too small to support people, or valuable minerals rights were controlled by the state. In the last quarter of the 20th century, beginning in Australia, many indigenous groups formed political organizations and successfully regained more effective control over many of their territories. The

struggle for land rights and economic independence has been the central issue for indigenous organizations.

RICH AND POOR IN THE GLOBAL SYSTEM, 1950–2000

The global-scale world system that was already in place by the beginning of the 20th century has gone through a further organizational transformation since the global crisis of war and depression from 1929 1945. This transformation involved the construction of an elite-designed framework of international governmental institutions that included the International Bank for Reconstruction and Development (the World Bank) and the International Monetary Fund (IMF), both products of the United Nations Monetary and Financial Conference held at Bretton Woods, New Hampshire in 1944, the United Nations (UN, 1945) organization itself, and the General Agreement on Tariffs and Trade (GATT, 1947), and the GATT s successor, the World Trade Organization (WTO, 1995) (*see* **GATT (General Agreement on Tariffs and Trade)**, Volume 4; **WTO (World Trade Organization)**, Volume 4). According to the preamble of the UN Charter, these new institutions were utopian visions designed to save succeeding generations from the scourge of war and for the promotion of the economic and social advancement of all peoples . The outcome of this transformation was a world system dominated by nance capital. By the end of the 20th century, money and the exchange of nancial instruments became more important than the movement and production of physical goods and services (Barnet and Cavanagh, 1994).

The modern world system is not a self-organized system operating under the invisible hand of a global free market; it changes in response to pressures from speci c interest groups with unequal power. Governments continue to exercise sovereign rights over territories and are the primary agents in international political society, but as we have seen, a centralized global government would be too costly to be effective. Various non-governmental organizations (NGOs) have become new actors in an emerging transnational civil society. New institutions are being designed by the interaction of NGOs and governments to deal with a multitude of speci c global issues (Young, 1997). The great transformation from industrial to nancial capital made commercial elites more in uential than political rulers. Those who bene ted the most from the global ow of nance capital at the end of the 20th century were an estimated six million individuals who each possessed investable assets of more than a million dollars. In 1997 the world s multimillionaires collectively controlled $17.4 trillion (Gemini Consulting 1998), which was more than half of global gross domestic product (GDP), yet they constituted less than 0.1% of global population. The world is now directed by economic decision-makers who are guided by the utopian ideals of laissez-faire capitalism that call for aggressive reductions in the regulatory power of governments, the removal of all trade barriers, and global management by negotiations among private, self-selected interest groups with very unequal power. These changes are designed to further accelerate global economic growth, on the assumption that growth will bene t everyone (the *trickle-down theory*). Unfortunately, in spite of the utopian objectives of the UN, the problems of scale and power increased after 1945. Although wealth continued to accumulate in the core of the world system, by the end of the 20th century much of the world was more impoverished and the global system was less sustainable than ever before.

Accurate assessment of human welfare during the postwar period is impossible because there are no accurate gures for worldwide wealth and income distribution. However, the World Bank estimated in 1990 that more than 1 billion people were living in absolute poverty with *per capita* incomes of under $370 dollars. Three billion people lived in the 45 low income countries, with *per capita* incomes under $660. The average infant mortality rate in these poor countries was 8-fold greater than in the 24 high income countries where 812 million people lived. Raising the poverty line, and allowing for lognormal income inequality within each country suggests that in 1965 there were 2.8 billion (85%) poor and 50 million (1%) rich in the world (Bodley, 1999b, 2000). By 1997 there were more than 4 billion (70%) poor people, and 310 million (5%) rich people. Thus, economic growth reduced the *proportion* who were poor, and slightly increased the proportion who were rich. However, the absolute number of poor increased dramatically, far outpacing the absolute increase in the rich. This suggests that if we accept this global standard of economic well-being, growth since 1965 impoverished far more people than it enriched.

This ampli cation of poverty during the 20th century duplicates the similar impoverishment process during the earlier transition from feudalism to mercantile capitalism, and again during the transition from mercantile to industrial capitalism in Europe and America. Both of these great transitions did little to change the pre-existing base of social inequality, but because of scale effects, they also produced tremendous increases in wealth and power at the top of the social hierarchy. At the same time, given high levels of inequality, even small improvements in the material level for people at the bottom of the hierarchy, in combination with new economic conditions, created new incentives for people to produce larger families. These changes created an unprecedented era of population growth. However, inequality, not population growth, was the primary cause of poverty. Amartya Sen (1981) pointed out that people died in modern famines not because of food shortages, but because inequality denied them access to income and productive resources.

One of the guiding justifications for the globalization of capital-intensive agriculture was that it was the only way to feed the world. However, malnutrition has proven to be an intractable social problem, rather than a technological problem. The Food and Agriculture Organization of the UN (FAO, 1999) concluded that there were more hungry people in the world in 1997 (830 million) than the entire population of the world (720 million) in 1750! Many under-nourished people were marginalized by more competitive capital-intensive enterprises, or by degraded environments. The chaotic transition from state socialism to new forms of capitalism in Eastern Europe produced 26 million undernourished people by 1997. When the concept of malnutrition was broadened to include vitamin and mineral deficiency, and over-consumption, as well as calorie and protein deficiency, it was estimated that three billion people, half of the world's population, were malnourished by the year 2000 (Gardner and Halweil, 2000). This is equal to the entire population of the world in 1960! Forty years of economic growth may have actually magnified malnutrition.

The power-concentrating effects of economic growth can be illustrated in Washington State, in the Pacific Northwest of the United States, where between 1960 and 1995 both population and *per capita* personal income doubled (in constant dollars). Washington benefited enormously from global trade in aircraft, information technology, and agricultural commodities, but these benefits were very narrowly distributed and economic power became highly concentrated. A close look at the distribution of property ownership showed that as individual urban places grew larger, home ownership rates declined, and the holdings of the largest property owners steadily increased (Bodley, 1999b). Villages with populations under 2500 people displayed the most equitable distribution of property assets and business revenues. Corporate business and remotely owned businesses became increasingly important in larger urban places, and larger businesses captured a progressively disproportionate share of total sales volumes. In cities with populations of 100 000 or more, the top 3% of businesses received more than 80% of business revenues. As wealth became more concentrated, the elite created exclusive urban places, where ultra high property values formed barriers against non-elites. By 1998 individual social power was becoming grotesquely distorted by the phenomenal growth in global information technology corporations. The collective net worth of Washington's billionaires was already nearly twice the value of all deposits in all the commercial banks in the state. Measuring their income as increase in net worth, in 1998 the income of Washington State's 11 billionaires was already 28% of the total personal income in the state, and was growing at 35% a year. Greater Seattle's economic elite occupied the same power position in the world as London's economic elite in 1600, or Boston's elite in 1850, and they too were personally transforming the world by their decision-making. Disproportionate power of this magnitude is clearly the product of scale, and it has profound implications for the future development of humanity.

The global system seems to be approaching, and may have already exceeded, a scale threshold at which elite-directed, capital intensive commercial development becomes unsustainable, even assuming further technological miracles. It would be reasonable to predict that the power-concentrating potential of globalization under financial capitalism will soon be restrained, and perhaps reversed as new democratic political movements in the currently most developed centers of the global system press an effective argument for economic democratization. As more and more people feel disempowered by global markets and giant, monopolistic corporations, there will be strong incentives for political and economic decentralization. This decentralization of power may be accelerated by persistent political and economic collapses in impoverished peripheral areas that will force radical rethinking of the international development process. Economic democracy will require a restoration of economic power to households, small-scale producers, local and regional markets. This change could be supported by new local currency systems, and stronger local governments, even as large businesses and national governments give up power. Just as disenfranchised 17th century Englishmen developed the first modern political party, the Levellers, that helped replace the powerful concept of the divine right of kings with the radical new concept that political power originated with the people, today people can form new political parties and take back the power they have granted to giant commercial corporations. It will become increasingly obvious that information technologies make it feasible for the majority to use less capital-intensive production and distribution systems. That will strengthen local communities, and produce a very high quality of life for most people. The economic efficiencies of small scale will be quickly realized as local production and distribution systems replace the costly long-distance movement of materials, so that overly rewarded corporate elites and great private investors become unnecessary. The idea of economic globalization driven by all-powerful commercial corporations and great concentrations of finance capital will be a quaint anachronism, like the idea of divine kings.

Technological Society and its Relation to Global Environmental Change

ESTER BOSERUP (Deceased)[†]

[†] *Independent Consultant*

The influence of technology on environment, and vice versa, is a relatively new subject in scientific discussion, but it has been crucial in human history. Historians divide human history in technological stages: the first stage when small human groups subsisted on wild food, then the invention of agriculture, then urbanization, industry, and now an ongoing change from the industrial society to the electronic age. Since the industrial revolution in Western Europe a couple of centuries ago, there have been more and more examples of negative effects of technological change on the environment, fauna and flora, and also on human life.

ADAM SMITH AND MALTHUS

The basic relationship between technology and environment is strongly influenced by a third factor: population size, as was pointed out two centuries ago, by the classical British economists Adam Smith and Malthus. They agreed on the crucial role of population change for human development, but while Smith thought population growth was a positive factor, Malthus thought it had negative effects. Smith's view was the generally accepted one: child mortality was very high and the family wanted to have many children to ensure that some would survive. Rulers also favored a larger population. Many inhabitants meant many productive workers and many soldiers to win wars and conquer additional territory. But because he observed the beginning of the industrial revolution, Smith added that population growth would not only increase the number of workers, but also their production per head, because it would make further specialization of labor possible.

Malthus' essay was a great sensation. He applied an ecological view, arguing that population growth reduces average incomes, because he considered the globe with its natural resources a constant, so population growth would reduce natural resources per head and increase mortality due to insufficient food production. The carrying capacity of the globe could not be exceeded.

In retrospect, we can see that they both had a point. Population growth can have both positive and negative results, depending partly on the relative strength of the positive and negative factors, but also on the strength of a number of other factors, which economists and others, who use simplified models, fail to take into account – first of all social and cultural factors. Therefore, we have neo-Malthusians who put great emphasis on the negative results of technological changes, which pollute air, fresh water, and soil, and threaten human life and health and the survival of fauna and flora. And we have anti-Malthusians, including many neoliberalists, who downplay the negative effects of modern technology on the environment, while focusing on the positive effects on average incomes. What we lack is an accepted theory of how all the relevant factors play together in the complicated process of economic and human development (Boserup, 1996).

Malthus overlooked that carrying capacity is not a constant because there can be substitution between different resources, be it labor or capital investment as replacement for land or one metal for another, and the type of substitution which is possible depends on the particular resource endowment and other conditions for resource transfer or invention in the region under investigation. In other words, it is necessary to use a historical approach to answer the question of effects of major population change on technology and environment (technology is defined as including both material and method).

Specialists from many disciplines have studied the relationship between changes in technology and in environment in addition to ecologists and natural scientists. One broad group consists of economic, medical, cultural, and general historians, another of archaeologists, anthropologists, and demographers. These groups have focused on historical changes in technology and environment in different parts of the world at different periods. But the problem has also been studied in a different way, concentrating on recent changes in the developing countries. Such studies have been

made by researchers from many disciplines in universities and other institutions that focus on aid to developing countries. In this essay both methods have been combined, for instance by comparing the process of ancient urbanization in Asia and the Middle East and its relation to environmental change with the much later process of urbanization and industrialization in Western Europe under different environmental conditions.

THE DYNAMICS OF LAND USE

Ten thousand years ago, or earlier, some human groups changed from hunting and food gathering in forested land to shifting cultivation, felling the natural vegetation by fire, sowing or planting seeds or roots, and after a few years when yields declined, repeating the operation in another spot leaving the preceding one fallow for two decades or more, until soil fertility had been fully regained. However, as their population continued to increase, the cultivators had to shorten the fallow and only bushes had time to invade the field. With further growth of population, recultivation had to be made when only grasses had invaded the land. Forest fallow, the first step of shifting cultivation, is still in use in thinly populated parts of many developing countries in all continents, for instance in the Indian Himalayas and in tropical Africa (*see* **Shifting Cultivation and Land Degradation**, Volume 3).

If this type of gradual intensification of land use is allowed to go on, without the cultivator family carrying green manure or dung to the field to preserve soil fertility, shifting cultivation is *unsustainable* and the land becomes sterile, but whether the process is *renewable* depends on the climate. With too little rain the land may become a desert, but with enough rain the original vegetation may come back, and the whole process may be repeated. However, if the cultivators have preserved soil fertility by manuring the fields with green manure or dung, and their populations continue to increase, they could go on from bush fallow, to more and more intensive short fallow systems, to annual cropping and, if the climate allowed it, to multicropping. This was, in fact, the way most of world agriculture developed before the industrial revolution created substitutes for the natural manure, and the human labor needed to apply it. In other words, the intensive systems of agriculture, which are used today in densely populated countries that still use traditional systems of agriculture, are repetitions of systems applied millennia ago. Land use is not static, but can be, and often was a dynamic adaptation to changes in population size and environment, and the process seems to have been similar in many parts of the globe (Boserup, 1965).

The historical process replaced less land per head by more labor for current operations and investment in land improvement, including terracing of mountain slopes and leveling of land, irrigation and draining. Gradually, over centuries or millennia, the environment changed. The landscape was transformed from a large forest with a few hunter-gatherer families to one of villages surrounded by arable fields, grassland for domestic animals and some forest for gathering of fertilizing matter, timber and fuel-wood.

These processes motivated the change of tools by transfer of technology from more advanced neighbors or invention by trial and error and speculation, from digging sticks to hoes and to ploughs drawn by oxen or horses. Technological change is seldom exogenous, i.e., accidental or made by a so-called genius, but endogenous changes may be made if the motivation becomes strong, due to population change, or some other factor, often a lost war in the case of weapons. In agriculture, increasing local population with need for additional food production promoted an endogenous process of technological change, which augmented the carrying capacity of the land by using the increased labor force for current operations and labor investment.

With intensification of agriculture more use was made of female and child labor. Already among hunter-gatherers, women and children took part in food gathering, but with shorter fallow the share of work performed by women and children increased until the system required very hard labor by the whole family all year round, as was documented by Lossing Buck in his research on China in the 1930s (Buck, 1937).

The increasing use of family labor had, sometimes at least, a profound influence not only on family life, but also on culture, and even religion. Forest people believe in forest spirits and use sorcerers and sacrifices to ask for protection. Sorcerers seem to be the first professional group in human history; and in the Indian caste system the priests, the Brahmans, constitute the highest caste. But many agriculturists, for instance in Southern India, sacrifice to local female fertility goddesses to obtain a good harvest, while pastoralists sacrifice to male gods to obtain good results from their flocks of animals. The later disappearance of goddesses in most of the world seems related to the reduction of the role of women in the agricultural economy when the plough came into use, and to her lower status compared to that of men.

The patriarchal system, where the male head of household can dispose of the labor power of other family members, led to intensification of food production through labor-intensive technologies. The right of adult men to dispose of the labor of other family members does even today encourage a pro-natalist attitude, polygamy, and keeping children away from school, even when there is free access to schools in the neighborhood.

The increasing intensity of land use changed not only the use of family labor, but also land tenure. As long as the local population is small, there may be free access to forest, grazing and cultivable land which has regained fertility by

fallow; with a larger population, only the local population has full rights to land, while foreigners must pay crop-shares or work as slaves, tenants, or wage workers, with or without the right to graze animals in village grazing areas, and gather fuel and food in the forests surrounding the village.

Until the middle of the 20th century diseases, including epidemics, to which the local population had not developed resistance, had kept long-term rates of population growth very low in developing countries, and – similar to Europe in earlier centuries – there had been periodic large declines of population, caused by epidemics and wars, often followed by forced migration and hunger. But during and after the Second World War a scientific effort was made to combat disease by means of modern technology also in many non-industrialized countries and colonies – the result being a population explosion, due not least to a large reduction of child mortality.

Because of the general acceptance of Malthusian theory in the industrialized countries, this acceleration of population growth created widespread fear of future world famine. So, similar to the transfer of Western medicine to developing countries, it was decided to start research aimed at transferring other modern Western technologies to densely populated Asian countries, where the problem was expected to become worst. Two types of research were started: one was aimed at improving the technology of contraception, the other was agricultural research aimed at raising crop yields by use of Western techniques, such as the use of chemical fertilizers and development of better seeds – the so called *Green Revolution* (*see* Green Revolution, Volume 3).

Green Revolution technologies can only be successfully introduced in areas with a reasonably good infrastructure: good transport facilities for both inputs and outputs, storage facilities, access to agricultural advisers and other extension services, and perhaps local research stations. All this is unavailable in regions of subsistence production and is not likely to be provided in the least developed countries, or in subsistence regions of large countries with much better prospects for agricultural development in more advanced and more densely populated areas. Therefore, the Green Revolution was promoted in densely populated Asian countries, simultaneously with improvement of the rural infrastructure in those areas, if necessary. The research was highly successful in stimulating production. However, both in the Asian areas for which it was designed, and in the Western industrialized donor countries, production increased so rapidly that the feared appearance of world shortages became one of embarrassing food surpluses. It also contributed to these unexpected surpluses, in that the rapidly increasing rural labor force in areas that continued to use traditional labor intensive technologies made it possible either to expand the area under cultivation or to increase cropping frequency.

When food surpluses increased in the industrialized western countries, their governments decided not to reduce government support to agriculture, but instead to give food aid to developing countries, and to lower export prices for food in order to be more competitive. Food aid and subsidies to food exports were granted not only to densely populated, but also to sparsely populated developing countries. But in many cases, a small population is not due to especially unfavorable natural conditions for food production, but it is the small home market, and lack of access to export markets, which force rural populations to remain subsistence producers, or to migrate to mines, towns or foreign owned plantations.

Many governments in developing countries welcomed the chance to supply their increasingly populated towns with cheap food, or to sell the food with a large profit. In the first case the effect was a discouragement to local agriculture, and food exports from the industrialized to the developing countries became very large.

In Asia, the Green Revolution technology, the increasing rural labor force, and the large food imports, combined to satisfy the effective demand for food without the need for investments in expansion of the cultivated areas. But it would be wrong to interpret this as a sign of lack of reserves of uncultivated, but cultivable land. If it should become impossible to increase crop yields much further, the Green Revolution technology can be modified with more emphasis on land improvement by investment in hitherto uncultivated land and on further cropping intensity. The possibilities for further multiplication of food production are often overlooked because hunger and malnutrition among the poor are wrongly interpreted as lack of the capacity of world agriculture to produce sufficient food. Evans rightly talks about well-intentioned scientists who seek technological solutions to problems of social and economic inequity (Evans, 1998).

Like other major technological changes, the Green Revolution had profound social and cultural effects. The income differences between areas with and without a Green Revolution became very large, and in the former there were important changes in family and fertility. When chemical fertilizer, pesticides, and mechanized inputs reduce the demand for the type of operations that were hitherto performed by women and children, the motivation for the male head of the household to be polygamic, and have a large number of children, is reduced or eliminated. Therefore, modernization of agriculture is accompanied by reduction of polygamy and fertility, except where strong religious inner and outer resistance against birth control delays the process, perhaps for a long time. Also, when children are less needed for agricultural or other work, they are more likely to be sent to school, but in many cases to schools, which are hostile to cultural change. In all cases, however, the reduction of fertility and agricultural toil create

a very large improvement in the health and position of women.

These effects are visible by a comparison between Asian areas with Green Revolution, and sparsely populated African countries. In the former, fertility is declining not only in urban, but also in rural areas. By contrast, there is much less fertility decline in the sparsely populated African countries, and it seems usually to be limited to urban areas.

MOBILITY AND URBANIZATION

After food production, the creation of urban centers is usually considered the next important step in technological development. Nearly all ruins of ancient towns are found in Asia and the Near East, a region with a dry and warm climate different from the cold and rainy climate of Western Europe. Both their early towns and their large cities antedate those of Western Europe by millennia, although insufficiency of rain only allowed agriculture at river sites, where water was seeping in, or with irrigation. It seems that we have here one of the many examples where a handicap – in this case shortage of water – proved to be an advantage, because it stimulated invention, in this case of irrigation technology, both for food production and for transport.

As long as their population was small, the cultivators lived on the shores of the river, or farther away from it, if there was natural seasonal overflow of the river. When the population increased, the people helped the natural overflow to spread more by digging small terraces on the mountain slope beside the river; and leading the water along these, they spread it by removing a few stones from the edge of the terrace.

Another step in the development of irrigation was to dig canals in the plain below the mountains or hills from which the flood came, to spread the water more widely, thus increasing the area under cultivation. This was followed by a crucial technological change. Construction served to lift the water either by gates or dams, or by water-powered machines, i.e., shaduffs and waterwheels. In other words, the use of water power had been invented, and it had the additional advantage that it benefited both food production and transport of products and people, which now could move up-river even when unassisted by sails and wind power. So, also in these natural conditions, the increase of population motivated technological change.

Not only in recent technological development, but throughout human history, changes in mobility and communication have been of crucial importance. In early times, many human groups depended solely upon human legs and perhaps primitive boats for mobility, but many pastoral peoples had large mountable animals (horses, dromedars, camels) and were therefore much more mobile than were the hunter-gatherers and cultivators discussed above.

The climatically dry and semi-dry zones of Asia and North Africa have for millennia been inhabited by pastoral peoples, either because their habitats have always been dry for climatic reasons, or perhaps have become so by human maltreatment of fragile land. Pastoralists subsist mainly by the products of their animals, supplemented by some vegetable food. If the group increased in size, they might make over-intensive use of the natural grazings and spoil the land, but sometimes they would avoid it by spreading more and more widely, and in large semi-dry areas they might become nomads, moving with their animals and tents, if possible by mounting the animals.

The diet of pastoralists is richer in proteins than that of cultivators, and they are usually larger and stronger than cultivators, who subsist mainly on vegetable food. This, together with their much larger mobility, made them a formidable enemy for the cultivators in the river valleys. The nomads attacked their villages, enslaved their inhabitants, and made themselves rulers of the area, using the villagers to provide themselves and their families with vegetable food and domestic, sexual and sometimes military services. If a pastoral people came to rule a number of villages, their descendants might become hereditary nobility between the ruler and the subservient population of peasants.

The family system and other cultural patterns of pastoralists are different from those of cultivators. Large animals belong to men, and mounted animals are a status symbol for male pastoralists. One may ask if a similar type of stratification had emerged in Europe, where the horses became a symbol of the high rank of the hereditary nobility that went to war on horseback, held tournaments and horse races and monopolized the right to hunt on horseback in the forests.

Carneiro has suggested that it was a condition for early urbanization that the population lived in circumscribed areas, i.e., areas surrounded by deserts, steep mountains or seashores, which forced the inhabitants to intensify food production if they must feed an increasing population in that type of environment (Carneiro, 1998). If the circumscribed area was as large as in Mesopotamia and the large river-valleys in India and China, a sufficiently large and dense population could produce and transport enough food for creating large urban centers at an early date. Existence of large towns and cities depends on transport networks for food to the non-agricultural population living in the urban centers. Road transport was inefficient over long distances but a dense network of canals made supply to large towns possible – for instance in China. But later, in the railway age, the Chinese canals proved to be a handicap because of the many bridges that had to be built. Thus, from being a technological leader until around 1500 AD, China, after

the industrial revolution in Western Europe, turned into a non-industrialized developing country.

In river valleys of Asia and the Near East, nomadic peoples from the Central Asian mountain range managed to create huge empires by conquering many hundreds of villages belonging to many different peoples, and using the inhabitants as soldiers. Wars were the means to get soldiers for further conquest, and construction workers for fortifications and embellishment of towns.

There were also productive infrastructural investments: large canals for transport of supplies and persons, and large dams for irrigation and expansion of the network of canals. In old times, large dams were made by an army of manual workers, and this technique continued to be used in independent India. The Indian government wanted to provide work for both local people and poor immigrants from other parts of India. It was a striking contrast to the simultaneous road building by the Americans in Vietnam, who used ultra-modern American mechanized equipment operated by American personnel.

At the time of the old empires, there were violent fluctuations in population, and the cruelty of the empires, both in war and peace, has been assumed to be a major explanation of these fluctuations, but, as already mentioned, it seems likely that a major cause of the fluctuations was epidemic diseases. Of course slaughter and famines among the fugitives contributed to the catastrophe.

Today there are lorry transport routes all over India and AIDS has followed them. In Southern and Central Africa the epidemics threaten to be even worse than the old killers from earlier centuries. World population was not stationary before the demographic transition, as Malthus believed, but was slowly increasing with intermittent sharp declines, where epidemics are supposed to have been a larger killer than warfare. The means to avoid an epidemic was to flee to another area, thus spreading the epidemic further.

SUPPLY OF POWER FOR THE INDUSTRIAL REVOLUTION

Western Europe had little urbanization before the industrial revolution. Because of the abundant rain, irrigation and water power never attained the importance it had in Asia, but Western Europe imported the techniques of water-wheels, on its small rivers, for milling of cereals and other purposes. In the 11th century, England had more than 5000 watermills in operation.

By contrast, Western Europe with its long coastal lines from the Mediterranean to the Baltic Sea made more use of wind power for long-distance transport of products and persons than did Asia. With strong motivation to improve shipping technology, Western Europe succeeded in dominating the whole world in the 19th century, by means of its colonization policy in the other continents. This was a big advantage for a region, which was relatively poor in natural resources.

From an early age there were caravan routes inland between China, the Black Sea and the Russian rivers and lakes, and later trading routes along the Asian coast between East Asia and Europe. At the European end the trading routes became longer and longer, until European coastal settlements on the Mediterranean, the Atlantic coast, the North Sea, and the Baltic had become active participants in the Asian trade, with large government-owned or government-supported Asiatic Companies.

At the first stage of this development, the boats and small ships could only carry light goods, and the trade consisted of luxuries (silk, fine textiles, spices, precious stones and metals, processed or not) for the use of rulers and rich merchants in the areas served by the trade. But when improvements in shipbuilding made long distance transport of bulky and heavy goods economical, the Europeans expropriated deposits of ores, fertile agricultural land and forests behind their trading stations in other continents, and used them to produce raw materials or semi finished products for exports to Europe. When improvements in navigation made Atlantic crossing safer, the Europeans established themselves in America, produced tobacco, coffee, cotton and other crops in monoculture, partially with use of slaves bought or caught in America and Africa. The Atlantic crossing was followed by exploration of the coasts of other continents, and many of the areas where the trading stations were located ended by becoming formal colonies of European countries.

Because most of the products exported from the colonies were owned by European companies and produced by cheap dependent non-European labor, colonial trade was very unequal, with large imports to Western Europe, and small exports – of which a share was for consumption by the European civil and military personnel and businessmen who lived in the colonies. By continuing for centuries to deliver ores, timber and crops for a fraction of the real costs, the colonies actually financed a great part of the Western European industrial revolution. Moreover, as Needham has shown, a large share of what has been considered proof of Western European inventiveness, was in fact technology transfer from China, either directly or via the colonies (Needham, 1954). But technological change promoted inventiveness, and the imports of new techniques were followed by important inventions by European scientists and businessmen, including the steam-engine and the railway, which linked the European countries together physically and economically, while the steamship linked them better to their colonies in the East, South and West.

Because Western Europe made less use of water power than China, and only made use of coal much later, it eradicated much of its forests and imported timber from Sweden and Russia. Therefore, the Wooden Age lasted very

long in Europe, but gradually more and more industries shifted their fuel supplies from wood to coal or water power, though the iron industry still used charcoal to melt ore. As late as 1750, per head output of iron in Europe was lower than in the least developed countries today, and the military sector took most of the supplies. Iron production in Western Europe is a classical example of a crucially important demand-induced technological change, and for a time Western and Central Europe became technological leaders on a world scale, owing to their large deposits of coal and ore in locations that were favorably positioned to attract both raw materials and market-oriented industries (Boserup, 1981).

The Coal-Railway Age became a period of extreme centralization, both regionally and locally, with large rural–urban and east–west migrations in Europe. The industrial importance of Italy, which had neither coal nor ore, was reduced until the 20th century, when its deposits of gas were discovered and exploited.

Because of their access to raw materials produced by cheap colonial labor and expropriated land and mines, British and other Western European industrialists were very efficient exporters of industrial products and solidly in favor of free trade in the world market. But that did not prevent them from protecting their local manufacturing industries by means of high custom duties and later by quotas, because they had to pay much higher European wages, when the colonial products were processed in Europe. The result became the well-known pattern of colonial trade where the colonies delivered food and raw materials to the industrial countries, while Britain and other colonial powers delivered manufactured goods to the rest of the world.

The industrial revolution promoted investment in private and government infrastructure: roads from railway stations and harbors to customers and other ancillary urban or rural services. Moreover, military technologies were improved and new armament factories built. In the military sector, as in the civilian, there was a beginning of the coming change from reliance on large numbers of soldiers and unskilled labor to more reliance on equipment and skilled specialists. Labor shortage was no more a permanent feature – from now on it alternated with unemployment.

The industrial revolution did not only create the business cycle, it also created the serious problem of pollution of the environment. Although there were accidents, and sometimes salinity, the Asian type of reliance on water power for industry and transport was a non-polluting technology, but in Europe the change from wood to coal had serious consequences because of the smoke. Though the burning of wood also produced smoke, that of coal became much worse and promoted tuberculosis, especially in mining and industrial districts, and in urban areas where the households used coal for heating. Also the new railways produced smoke in the densely populated areas, which they served. Moreover, the rapid growth of both the mining and the processing industries resulted in concentrations of population in the most polluted areas, which were becoming both unpleasant and unhealthy. Because of the rapid urbanization the immigrants had to live either in old houses or in self-built huts, and the towns became surrounded by huge slums, which contributed to an increase in mortality and made room for employment of further immigrants.

The natural landscape was transformed by the new ugly construction of mines and factories. This gave birth to the first protest movement: the *romanticist movement* at the end of the 18th century, which regretted the damage made to landscape, fauna, and flora. The environmental movement was born of the industrial revolution.

Like earlier structural changes in the economy, the industrial revolution in Western Europe was accompanied and followed by major political, demographic, occupational, and cultural changes. Organized labor movements appeared, due to the frequent periods of unemployment with downward pressure on wages. The new industries helped to put downward pressure on male wages by offering employment to young unmarried women with the result that the marriage age increased, reducing the birth rate, but for the poorest the increasing recruitment of child-labor in industry provided an inducement to continue high fertility and the decay of family life of industrial workers. Moreover, as a result of the industrial revolution, a new middle class of technicians and other specialists appeared, both in private enterprise and in government, and became a more important part of the labor force and of society in general. Following the French Revolution, secularization spread among intellectuals and the feminist movement was born, giving rise to employment of middle class women.

In the 19th century, more and more industrializing countries introduced suffrage for men but, except in New Zealand, where women had to wait until the next century. The concept of human rights was until recently defined more narrowly than today, and the declaration of human rights by the French Revolution and the American Constitution covered only men. Not only were women excluded from the human race in the 19th century, but also colored natives in the colonies. Not only most Europeans in the colonies and at home, but also much of European science, agreed with the racist theory of European superiority in relation to other races, both blacks, reds, and yellows, and tried to explain racial difference by hereditary differences in, e.g., the shape of the skull. The embarrassing problem of technology transfer from Asia was avoided by classifying the ancient Greeks as Europeans and focusing higher education on the writings of Plato and Aristotle, forgetting about their oriental predecessors.

The attitudes of European missionaries in the colonies were of course different, but usually they considered and treated the natives as children. Many whites in the colonies

regarded only white people as real human beings, while members of other races were either considered sub-standard humans or not humans at all, a good excuse for killing or enslaving them in spite of the attitude of the European churches. In conformity with these racial theories, the Europeans arriving in Canada and Australia expropriated the whole territory declaring the land empty; these actions are today occupying the courts and generating public debates in both countries.

Before the 19th century the loyalty of European populations had usually been to their ruler or to their local region, whether independent or not, but from the 19th century onwards, it changed in many cases to strong feelings of attachment to the Nation, i.e., the area under the same government, which had become strengthened by the appearance of national railways, mining centers, large industries, and increasing national government bureaucracies, civil and military.

After the industrial revolution, Western European governments had made efforts to transform the European part of their possessions into national states, partly by propaganda and other support for what was labeled *national culture*, and partly by propaganda against or suppression of minority cultures. A strong means to obtain this was the increasing school attendance by compelling both teachers and pupils to use the national language only. The growth of armaments and other national industries and establishments, and the competition between the European countries in exports and acquisition of additional colonies, also contributed to a feeling of national unity. Not only were literature and art strongly influenced by the national movements, but also science.

DECOLONIZATION AND NEOLIBERALISM

The industrial revolution had important long-term effects on military technology and world politics. Having helped France and England to win two world wars, the United States became the uncontested technological world leader, a change that was related to the environmental differences between these areas. Railways had been of central importance in the European process of industrialization, as already mentioned. On the North American Atlantic coast they were built early, but not over the enormous stretches of near-empty land, in the interior of the continent. Transcontinental railways were built with French and Russian capital, using local wood instead of coal, but they were unprofitable, and the foreign investors lost their money before the railways could make both ends meet under American ownership.

Once more, however, a handicap became an advantage, because the poor profitability of many railways induced American business and scientists to develop better means of power and transport, that could serve thinly populated areas over very long distances better than the railway. The result became the American dominance in the automobile and aircraft industries, which derive power from oil, a product that was available within their own territory. Automobiles offer more flexible transport than the railway, and aircraft contributes to globalization. For a time their influence on the environment was positive, because they replaced the bulky and polluting coal by oil, but later both industries became serious polluters.

After the Second World War, the United States used its influence as a superpower to broker the liberation of the colonies of the European countries. The United States wanted this liberation, not only because of their own past history, but also because the colonial preferences in international trade discriminated against US exports. England and some other colonial powers accepted a peaceful liberation of their colonies, because many had become public burdens due to increasing expenditure on military and administration, and because liberation did not imply any change in ownership of private enterprises. To enable the former colonies to take over the costs of military and civil administration and other public infrastructure, the United Nations and some national governments created organizations of international aid to developing countries, and the World Bank provided long term finance for large scale investments in infrastructure and other major projects.

An international boom followed the process of liberation of the colonies. The colonial powers had wanted to keep the colonies as suppliers of food and raw materials, and as markets for industrial products, but after independence, many former colonies wanted to industrialize, and change their pattern of trade. Many obtained grants and loans from donors to cover the expected deficit. The American business community used the improved access to direct trade with former European colonies to create large multinational companies, followed by an increasing number of other countries.

Multinational companies apply the most advanced technologies in their production of goods and services for the world market. Usually, they have their headquarters and top managers in the United States, Europe or Japan, with dozens or hundreds of enterprises spread over several continents. Unskilled labor is recruited where it is cheap, and qualified labor, technicians and computer services where wages are low, but qualifications high – for instance in India.

The liberation of the colonies has allowed many developing countries to increase employment and incomes by becoming seats for one or more of the enterprises belonging to a multinational company or a sub-deliverer of materials or services. The multinationals are efficient producers in the world market, because they are cost-reducing for their customers, but often they are even worse despoilers of the environment than local industries, because they can choose

to operate in the countries where they pay the least for protection of land and people, as was the case in Bhopal in India in 1984, where more than 5000 members of the local community were killed by a chemical leakage.

Modern technology has saved millions of human beings, but also destroyed millions. Many modern inventions threaten human health or survival, while others contribute to the deterioration of the physical and biological environment and some do both. More often than not, enterprises, government bodies, and municipalities dispose of their waste, polluted by dangerous metals and chemicals, into rivers and lakes, or ugly mine tailings, reducing the access to fresh water and making the Green Revolution poisonous.

Heavy agricultural machinery may despoil large areas of fragile soil. The oceans are polluted by in ow from poisoned rivers, cleaning of ships in open seas and many other polluting practices. In large cities, air pollution by motor traf c and domestic cooking and heating has become as unpleasant and dangerous to health as burning of coal was earlier. And nuclear energy, once considered a clean replacement for coal, has proved to be so controversial that calls for its abandonment are becoming strong and widespread. However, now it seems that better alternatives are on the way: more use of solar energy, perhaps combined with liquid hydrogen.

Pollution of the water in rivers, lakes, and oceans can be avoided or repaired, and municipalities and governments often try to achieve this, by charging payments for use of clean water and for misuse of fresh water, but these payments are usually so low that it is cheaper for the consumers to misuse the resources. Not only too low penalties, but also too high premiums can cause disasters. Because of the high premiums paid in the Soviet Union to producers who exceeded their production plan, collective farms in Uzbekistan neglected to fallow their irrigated elds, bringing desalinization.

To avoid or limit the misuse of natural resources, the producers should pay the costs of avoiding misuse, which is in most cases a fraction of the costs of repair, if that is at all possible. In many cases there are regulations which should induce or force producers to delay using new technologies, until suf cient scienti c investigations of the effects have been made, either by the producer or by government, but this is unlikely to be the case in countries that are eager to house subsidiaries of multinational companies.

The problem of who should pay, the multinational or the country where one or more of its enterprises are located, concerns not only environmental costs, but also costs of public infrastructure, for instance roads, harbors, airports, and unemployment insurance. However, neoliberal theory undervalues the importance of infrastructure in modern economies.

We meet the problem who should pay? whether we discuss environmental problems or the welfare state. Many American economists have an easy answer: the neoclassical school tacitly assumes that infrastructure costs are negligible, so what is right for a business enterprise is also right for the economy. The economists are right in pointing out that, if the local, national or multinational company is charged *more* than its indirect costs, the price structure cannot be the correct guide for the market and the investments, but they conveniently forget that this is equally true if the company is charged *less* than the true costs, including the replacement costs of necessary infrastructure, be it private or public. For the same reason, it distorts the structure of world production, when virtually all governments in the industrialized countries, whether they are members of World Trade Organization (WTO) or not, give subsidies to non-competitive national producers and pose restrictions on imports from effective foreign producers of goods and services.

The colonies of European countries had been handicapped in industrialization by the colonial trade system, but after they had become independent, many of them used the large grants of foreign aid in the rst period of independence to start ambitious programs of industrialization by investment in the types of physical and human infrastructure, which are needed for industrialization. Large infrastructures may take decades to complete and even longer before countries can begin paying back their loans; so many of the new projects proved to be more costly and took much longer to construct than foreseen, while in the meantime the 30 good years (1950 1980) were over. The neoliberal governments in the United States and England had reduced foreign aid, part of which was replaced by private loans or credits from international organizations especially the World Bank.

As a result, many of the former colonies became heavily indebted and had to cut down on their investment plans, sometimes by arresting half nished developments. Some nanciers, getting nervous, tended to make the loans shorter and shorter, until a crisis broke out in one developing country after another. Production and employment were sharply reduced, and the large informal sector broke down, because its customers lost their incomes. The informal sector in developing countries consists of small enterprises, often family industries that produce traditionally-made goods and services for worker families and the lower-middle class, who prefer the cheap prices in this sector to better quality and design in the modern industrial and service sector. Because it uses traditional technology, the informal sector provides a large share of the employment and self-employment in developing countries.

When the sharply reduced activities in both the modern and the informal sector made it impossible for large numbers of the urban population, and some of the rural too, to subsist, many, for instance in Africa, chose to return

to subsistence production in the villages they had left for the town, but this was not possible, or was less attractive, for earlier rural-urban migrants from areas where the Green Revolution had made access to land more difficult or impossible. Many others chose to migrate to the United States, Canada or Europe, many of them to larger towns and cities, which more than ever became melting pots for people of different races, nationalities, languages, beliefs, and past experiences.

In many of the developed western countries, to which not only economic, but also increasing numbers of political refugees turned in desperation, immigrants from less developed countries became more and more unwelcome, or were refused access, because of increasing resistance to immigration. This was so not only because the labor market was deteriorating, but also because of increasing resistance against having to live together with foreigners , especially if they belonged to a different national or religious group and had contradictory ideas on the role of women in the family.

To adapt to the international crisis, which created overcapacities in many national and multinational companies, more and more of these have chosen to merge in order to reduce their costs – especially by large reductions of personnel, both in developed and developing countries. For example, oil companies that had competed by constructing service stations next to each other discovered that the true costs of competition could be high. However, by cutting down on these expenses they added to the unemployment crisis in many of the countries where they operated.

The mergers were not a means to avoid or reduce competition, but were aimed at sharpening the competition between the remaining larger and stronger multinationals and between them and national, private or government owned companies. Instead of aiming at a strengthening of the world economy, by cooperation both within the private sectors and between these and the government sectors, national and international, the neoliberalists continued to destabilize both the national economies and the world economy by their continuing efforts to destroy their competitors, be they national or international, instead of focusing on the common interest in stable growth of the world economy.

The present prolonged crisis in most of the world markets is a repetition of the situation in the 1930s, when both mass consumption and investments continued to decline, until the new Keynesian policies increased mass consumption and promoted profitable investments. But today, capital-exporting countries prolong the crisis by their sharp cuts in development-aid in a period where sharply increasing income inequalities also reduce mass consumption, thus reducing the profitability of many investments.

GLOBALIZATION AND THE MODERN CASTE SYSTEM

From ancient times, large technological changes have been accompanied by and followed by fundamental changes in the economic and political organization of society, in religion, and secular culture. Adam Smith identified the process as more and more specialization of labor, while Marx interpreted it as a gradual change from an original one-class society, which after a long period of war between two classes, a rich and a poor one, ended with a lasting victory for the lower class, that had become the industrial working class.

But Marx's interpretation of human history was wrong. Neither before nor after the time of Marx, was human history a war between two classes; it is much better interpreted in terms of the Indian multicaste system, if this is modernized by adding the scientific community with its increasing claim to be accepted as the first caste. The ancient Indian system had three upper castes, the priest, the secular power (army), and the trader, with the rest of the Hindu population as sudhras , the fourth caste, and the adherents of other religions as non-caste foreigners .

If we interpret this caste system as a stylized description of world history, the first caste: the priest, replaces the sorcerer as the highest authority, after the shift from the gatherer to the producer of food, as mentioned earlier. The next step is a contest of power between the first and the second caste, the priest and the king with his army, a fight for power that, for instance in Europe, lasted many centuries. It became more complicated when the third caste, the trader (later: financier or capitalist) appeared, with urbanization and monetization, visiting villages as foreign tradesmen and lending money to the higher castes. The trader was often himself a foreigner; in Asia, Chinese or Indian; in Europe, Jewish. Sometimes he was massacred by caste members. In this period of history the European church was split into Protestants and Catholics, as explained by Max Weber.

The next step in the contest between the castes was *democratization*. The sudhras became the electorate, thus becoming legal contestants for power, creating alliances (nearly everywhere precarious) with one or two of the higher castes. Finally, we have the struggle between the four castes and the non-caste foreign group, be that a minority or a subjugated majority, as was the case in the colonies, where discriminatory treatment of castes and religions was a means to retain power.

The distinction between the members of the four castes and the non-caste group is even more divisive than the distinction between caste-members, and it explains why virtually all human societies have been more or less incessantly at war either with neighbors or in international or intercontinental alliances. For a particular people, wars were the means to become castes if they won, but non-castes

deep below all others if they lost. The latter brought a catastrophic decline of status and income, if not of life.

In addition to the three high-caste groups: the church; the government with its army; and the business world, modern societies have an additional caste, which like other castes tends to be hereditary: the scientific community – distinguished by high-level education and employment in universities and other scientific or modern business institutions and enterprises. When the new caste appeared there was a struggle, as in Iran today, between the new caste and the first caste, but it ended most often with a compromise.

Recently, the scientific caste has become much more numerous and stronger as a result of the development of computer technology. It is the beginning of the fundamental technological change from the industrial to the electronic age, which has been supported and promoted by the multinational companies and by many governments and scientific institutions.

The future change to the electronic age will bring mass-communication with English becoming the world language. This will make it possible for most of the future world population to be informed directly about conflicting points of view of different countries and castes, instead of receiving only or mainly the propaganda of its own group.

Already today, the spread of knowledge benefits from information in the media from private and public international and regional organizations, including the ones focusing on protection of the environment (*see* Global Forest Watch, Volume 4). The explosive growth of electronic information is of particular importance for schools in thinly populated and in poor regions, where illiterate children (and adults) can come in direct contact with the world by pictograms (icons) and images instead of being cut off from globalization by illiteracy.

Another group, which has benefited from the recent technological changes, are women from the new caste who have entered high positions by means of personal achievements or helped by heredity and education.

By its achievements, especially in the natural sciences, members of the scientific caste have become not only respected, but also feared by the other castes, the reason for the latter being that the scientific caste has obtained spectacular results not only concerning nature, but also relating to humans, their health and survival. A widely read book speaks of the *risk society*, where both rich and poor are threatened by the risks of modern scientific interference with human health and food (Beck, 1992).

The temptation is great to reduce cost and time, cutting short the time spent on research and development. The scientists, the laboratory, the producer, and even the government would like to be first to come to market; thus gaining in profit and honor. But in the past, there have been disastrous results of insufficient research, like the tragedy of the deformed Thalidomide-children, and, more recently, the lack of control with AIDS-contaminated blood. The damage is often discovered years later, and is in most cases irreparable. So the general public is roused to the risks of insufficient research, especially within genetic technology for food production and medical care.

The public case for strict control both with existing and new potentially life-threatening technologies is strong, and it is imperative that concerned scientists, producers, and governments combine their efforts to prevent misuse and thoughtless behavior.

In the international business community reaction to increasing globalization of the economy is positive, but that is not the case with most national governments, which are hamstrung by strong nationalism, which emerged in the industrialized countries in the 19th century and in the liberated colonies in the 20th century. With this background of increasing nationalism, it is not surprising that the meetings of the United Nations and other international organizations are often used to voice conflicting national interests, instead of promoting international cooperation as a replacement for wars.

Many adherents of economic globalization have a negative attitude to its cultural aspects. People with different cultures, religions, and customs have come much closer to one another, both because of immigration, and through increasing use of computer technology. For many, the reaction to this is negative. Because of nostalgia for the past and fear of the future, they revive abandoned old beliefs and customs, be they beliefs in spirits and fortune telling, customary dress, the patriarchal family pattern, or fundamentalist religious practice.

The revival of many shadows of the past, which have been sources of serious conflict, contributes to making the process of globalization more difficult. But it is not by returning to old customs of family and co-village preferences, or of racial prejudices, that the inescapable process of globalization can be carried out peacefully. In fact, we live in a period where increasing income differences, both within and between countries and continents, increase the risk that desperate individuals or governments will use the proliferating, more and more efficient, mass-killing technologies, and that they might succeed in eradicating all or a large share of humanity, deliberately or by error.

Relating to Nature: Spirituality, Philosophy, and Environmental Concern

FREDERICK FERRÉ

University of Georgia, Athens, GA, USA

Classical Greek philosophy had its origin about 2600 years ago. Human spirituality is much older. No one knows exactly when our early ancestors began to experience religious awe or fear or ecstasy, but paleontologists nd evidence of spirituality along with the tools and implements of the earliest remnants of Homo neanderthalensis as well as Homo sapiens. Burial rites and cave painting strongly suggest that with the rise of our species also rose deep feelings and comprehensive beliefs, shaping our relations to nature.

The details of prehistoric spirituality must remain a subject for speculation, but it seems likely that tribal adoption of totem animals in uenced hunting practices, and that religious taboos and fertility festivals were involved in the invention and carrying on of agriculture. Because the great shift, about 10 000 years ago, from the mobile hunting gathering life to the settled existence of agriculture, and eventually cities, represents the single most signi cant change in the human relationship to nature in the entire history of our species; the spiritual attitudes guiding these practices had enormous signi cance for the environment. Earth worship, Sun worship, beliefs in spirits inhabiting elds, streams, and trees; ritual inhibitions on eating and mating; and the rise of shamans and priests, guiding group practices and keeping calendars: all these laid the foundation for deeply felt attitudes on what was permissible or impermissible in human dealings with the natural environment. Some of these attitudes may continue to resonate in the present day, almost too deep for notice or discussion.

*Vigorous discussion, however, of the alleged huge burden of guilt born by Christianity for sponsoring damaging environmental attitudes was prompted by a 1967 article by Lynn White, Jr, an eminent historian, in the magazine, Science. White accused Christian spirituality of undermining reverence for nature by isolating the holy in a transcendent creator God alone, thus leading to a sharp divide between the sacred and the profane. European attitudes based on such a spiritual dualism, applied from the middle ages to the present, White asserted, reduce nature to a mere resource for human use and development. His prescription was to counter a dangerous spirituality with an environmentally more benign one, also present in the Christian tradition, particularly that of St. Francis, who saw the sacred in nature all around him and wrote hymns to Brother Sun. As can be imagined, a variety of theological responses greeted this landmark critique. The debates continue to reverberate (*see also ***Christianity and the Environment****, Volume 5;* ***Ecofeminism****, Volume 5;* ***Religion and Ecology in the Abrahamic Faiths****, Volume 5).*

Philosophical as well as theological worldviews deeply shape attitudes toward nature. Classical Greek philosophy struggled with the de nition of the human position in nature, therefore in uencing the sorts of attitudes deemed appropriate for humans to take toward the environment. These philosophical issues were intimately (and interestingly) entangled with theological ones in the rst fteen centuries of the Christian era, separating again in the modern era, during which they have continued to shape the norms of human relations with other creatures, with matter in general, and with other persons in society. The dominant philosophical modern world picture was dualistic, with humanity and all values on one side, and the rest of the world, valuable, if at all, only because humans might value it, on the other. Alternative philosophical views have challenged this dominant picture, but in the atmosphere generated by the alliance of philosophical dualism with the early modern science of Galileo and Newton, these challenges have found it extremely dif cult to ourish.

The environmental realities of late 20th and early 21st century modern industrial societies have shown the urgency of nding ways of relating to nature that will allow both human beings and the rest of nature to thrive.

Hence there are calls for reexamination of the religious and philosophical grounds for the attitudes which contemporary men and women express in their treatment of nature and each other. The alienation between culture and nature, mind and matter, value and fact, sacred and profane, transcendent and immanent, needs to be healed. Assuming that most of the resources for changing any culture from within need to be found among the de ning achievements of that culture, resources from ancient Greek philosophy, biblical religion, and science will be especially valuable in any step toward reforming western postmodern environmental attitudes and practices. But since environmental changes and concerns are global, it will be important that foundations be laid for a wider ecumenical dialogue with spiritualities and philosophies drawn from non-western cultures as well.

RELIGIOUS POLARITIES OF IMMANENCE AND TRANSCENDENCE

Although the spiritual beliefs and practices of prehistoric humans pose many unknowns, there are rich sources of clues to be found in artifacts left by ancient peoples as well as in the observed beliefs and practices of recent or contemporary peoples living in preliterate (in this sense prehistoric) societies. The latter societies often share much in common with ancient practices of food production, hunting, housing, and the like, and may be surmised to have at least analogous worldviews and attitudes toward nature.

The earliest religiously significant artifacts left by ancient humans and contemporary preliterate societies both indicate strong attitudinal connections to nature. The sacred is felt as pervasive through, dwelling fully within, the natural environment. At one pole, spiritualities of this sort, in which the sacred is perceived as inside rather than outside the natural world, can be called spiritualities of *immanence* (in-dwelling the opposite of *transcendent*). Animals are revered. Hunting and agricultural tribes alike relate in totemic identi cations with characteristic powers of familiar species. Statuettes, the Venus gurines dating from the Upper Paleolithic Period (approximately 25 000 BC), depict women with exaggerated secondary sexual characteristics, breasts and buttocks, and are taken to indicate widespread fertility worship over a large geographical area, including Europe and Russia. Thousands of gurines of animals, and stone plaques of animals and people, show how important nature loomed in prehistoric consciousness. Also from the Upper Paleolithic (c. 15 000 BC) are cave paintings (e.g., at the Lascaux Grotto in South-central France) of animals, mainly in France and Spain but also in the Urals, probably created for ritual and magic involved with sustaining herd populations and with preparations for hunting. These show intense human interest in and close observation of the natural environment.

After the rise of agriculture and civilization in the fertile crescent, earlier Great Mother and Earth Mother myths, preserved in writing by the earliest civilizations of Sumer and Akkad, trace all natural gods to dei ed female generosity. But male fertility gods were also of great importance in ancient times. In many Middle Eastern societies the god Baal played a central role in relating humans to the natural order. In the mythology of Canaan, he is lord of storms, thunder, lightning, springs, and moisture in general. One of his tasks is to ght a major battle with Mot, the god of death, every seven years. If he wins, humans are assured seven years of plenty; if he loses, seven years of drought and famine result. In addition, in an obvious seasonal cycle, Baal must ght an annual battle with Mot toward harvest time. Baal always loses this encounter and winter comes, but his sister, Anath, annually revenges Baal by killing Mot, thus allowing Baal, and a new growing season, to return to life. Astarte, sister of Anath and Baal, represents another important Middle Eastern deity of sex and fertility, as well as of war. She was worshipped as the primary divinity of Tyre, Sidon, and Elath but also had important followings in Akkad, Egypt, and Europe. In Akkad she was known as Ishtar; in Egypt her name became assimilated to Isis; in Greece and Rome she was associated with Aphrodite (Venus), Artemis (Diana), and Hera (Juno); all aspects of the Great Mother. Aphrodite was patroness of human sexuality; Artemis was mistress of the animals, both wild and domestic; and Hera was matron of all things female, patroness of breast feeding, comforter of women.

The opposite pole in relating to nature is that of *transcendence*, in which the sacred (envisioned as dwelling outside or above the natural universe) is carefully defended from contact with all this familiar landscape of crops, animals, war, and babies. In the cultural and religious melting pot of the eastern Mediterranean region in the second and rst millennia BC, nomadic Hebrew tribes partly assimilated, partly held themselves apart, in the struggle for supremacy between these two great attitudinal modes of relating to nature. As strongly re ected in the Bible, some of the Hebrews, on adopting agricultural and urban ways of life, were tempted to add also the worship of Baal and his fertility-oriented consorts to the worship of El or Yahweh, a deity associated with the more ascetic life of tents, sheep herding, and desert storms. Much to the offense of the stern supporters of tradition, many Hebrews tried to have it both ways, seeing the sacred in natural processes and indulging even in the ritual prostitution and sexual promiscuity accompanying agricultural festivals of planting and harvest.

Hosea, an early Hebrew prophet during the reign of King Jeroboam II (786–746 BC), had a wife who may herself have been a temple prostitute, to his great personal anguish and moral displeasure. Israel, the northern kingdom of the Hebrew tribes, is condemned by Hosea for likewise prostituting herself in observing the feasts of Baal, sharing her favors with paramours other than her true husband, Yahweh. Hosea foresees destruction of the northern kingdom, as punishment for the spiritual promiscuity illustrated by the fertility rituals he found disgusting. But in a striking oracle which he acts out, he redeems (buys back) his adulterous wife from prostitution to indicate that Yahweh, as faithful husband, will ultimately take back at least a cleansed remnant of the chosen people on whom he has established his covenant love.

Other prophets, like Amos, Hosea's southern contemporary, thundered against the dilution of religious commitment to Yahweh represented by Baal-inspired attitudes toward the immanence of the sacred, and drew primary attention back to issues of transcendent principles of social justice instead. Caring for the poor, the weak, the vulnerable, not sacrificial ritual or mere lip service, is where the sacred (what God ultimately cares for) must be located. Hebrew contempt for the fertility-related modes of spirituality showed itself from the time of Hosea and Amos in language as well. Earlier, Baal-terms had been accepted without discomfort. King Saul (ruled c. 1021–1000 BC) had a son, Ishbaal. Still earlier, Gideon, the judge, was known also as Jurubbaal. But Queen Jezebel, a princess of Tyre and Sidon who married King Ahab (ruled c. 874–853 BC), campaigned vigorously to make worship of Baal exclusive and mandatory, aiming to replace the worship of Yahweh entirely. This polarized the atmosphere and afterward led the very name Baal to be replaced sometimes by the Hebrew word for shame, *boshet*. Ishbaal became Ishboshet and Baal's sister goddess, Astarte, was renamed Ashtoreth, a compound of Astarte and boshet through which the Hebrews expressed their stern disapproval for her followers' excessive immersion in sacred immanence.

The textual analysis of the Hebrew Bible is complex and many layered. But eventually (by around 500 BC) the priestly tradition, whose authors were responsible for the creation story with which Genesis begins, absorbed and affirmed in stirring imagery the prophetic insistence on the transcendence of God, far above and beyond the realm of nature, formed as it was out of the chaos of the waters over which God's spirit brooded. In later interpretation, this story was taken to depict the creation of the material universe out of nothing , so utterly distinct must the creation be from its transcendent Creator. In parallel, in keeping with the prophetic ideal, the opposition expressed in the Ten Commandments against other gods and especially against graven images , or any likeness of anything that is in heaven above, or that is in the earth beneath, or that is in the water under the earth , strongly reinforced in early Hebrew spirituality the refusal to find the sacred anywhere in nature but only in the Lord your God, who brought you out of the land of Egypt, out of the house of bondage (Exodus, 20: 2–17).

This stern stress on history and justice made for striking contrast with the morally easygoing emphasis, in competing spiritualities, on finding the sacred immanent within nature, whether in animals or in storms or in the Earth's fertility. If the sacred in any worldview is understood as whatever is considered ultimately valuable, whatever is finally worthy of worship, then Hebrew consciousness came, over time, to locate the sacred exclusively in the transcendent God, eternal source of righteousness, standard of justice for human community, and paradigm of faithfulness to a covenant made and sustained despite the vicissitudes of history. Nature was significant not in itself but mainly as the non-moral stage upon which the moral dramas of history could play out.

Coming to this view of nature was a gradual process, and not without alternatives in the development of Hebrew spirituality. In Genesis itself stands an alternative creation story, older than the more familiar priestly story of Genesis 1. This older story of Genesis 2 depicts a different order of creation and a much closer relation between human beings, animals, and the material order. God creates the first man not out of nothing but, rather, out of dust from the ground (Genesis, 2:7), and creates the animals afterward as helpers for man, so that he would not be alone (Genesis, 2:18). The animals all get their names from their human fellow creature. The power to give names does recognize the unique gift of language enjoyed by humanity, but it does not by itself suggest alienation or domination. Finally, to make a more fitting helper, God makes the first woman from organic tissue removed from the man. *Differentiated mutuality* (different parts in positive relation) is the mood of this older creation story.

The later, principal creation story of Genesis 1, in contrast, does explicitly encourage domination. The first humans are commanded both to multiply their numbers and to subdue all the rest of nature for human use and profit (see Genesis, 1:28). The moral tone expressed in the verb *subdue* by its Hebrew original is not gentle. The same verb, kābash, is found in violent contexts such as conquering enemies on the field of battle, or even assaulting a woman by force (see Esther, 7:8). In this context, the various animals and plants are explicitly given to humans for rule and consumption. Humans, uniquely made in the image of God are intended to take dominion (Genesis, 1:26) by the Creator God himself, standard giver of justice and model of righteousness. Nature, far from being a locus of immanent sacred value, is seen instead as made up of things to be controlled and used.

Within the Judaism and Christianity that grew out of early Hebrew spirituality, internal tensions can be found between the attitudes of dominion and those of differentiated mutuality. In Jewish law, animals were sacrificed with good conscience, but, in contrast, farmers were forbidden to muzzle an ox when it treads out the grain (Deuteronomy, 25:4), suggesting attitudes of mutuality and fair play with animals. In Christianity, Jesus is shown withering a tree with a curse (see Mark, 11:2–26) and using a herd of swine as vehicles to send evil spirits over a cliff into the sea to perish (see Matthew, 8:30–33), but also, in a more tender picture, he is quoted as appreciating the value of ravens and lilies, though differentiating their value from that of human beings, which he holds to be far greater.

> Consider the ravens: they neither sow nor reap, they have neither storehouse nor barn, yet God feeds them. Of how much more value are you than the birds!

Also,

> Consider the lilies, how they grow; they neither toil nor spin; yet I tell you, even Solomon in all his glory was not arrayed like one of these. But if God so clothes the grass which is alive in the field today and tomorrow is thrown into the oven, how much more will he clothe you, O men of little faith?
>
> (Luke, 12:24, 27–28)

The spiritual development of Western Europe over the following millennia is complex, influenced from many sources, but Christian ambivalence about the natural environment continued, with a gradual loss of the sense of differentiated mutuality. Mystical world denial, influenced by strains of philosophical Platonism, drew attention away from the world of the senses and toward radically transcendent realms of the sacred. In this, Christianity took a different trajectory from Judaism, which (despite neoplatonic subthemes of its own) remained more of the earth, earthy, with less sharp distinctions between soul and body than came to typify the medieval Christian worldview. Even in Christendom, of course, practical work needed to be done, whether on feudal estates or in monasteries. But such secular interests were clearly distinct from what was ultimately important. Practical inventions abounded in the middle ages, released from restraints that might have been imposed by religions of immanence. Christian opposition to the Druids, for example, released the oak forests of Europe from the protection of Druidic veneration, transforming sacred groves into sources of lumber.

These developments, strengthening the dominion attitudes of European Christians, have continued until recent times, with important reinforcement from modern philosophy and science (see the following section), and they are still reverberating throughout the industrial civilization (now worldwide) that traces its roots to Christian Europe. In America, in the 1960s, some theologians embraced and celebrated our culture's liberation from entangling spiritualities of immanence, a liberation provided to modern secular civilization by Biblical stress on the exclusive transcendence of the sacred (Cox, 1966).

THE LYNN WHITE CONTROVERSY

One of the most important single challenges to Christian self-congratulation on environmental attitudes came in 1967 from a seminal, wide-ranging article published by the historian, Lynn White, Jr, in the journal, *Science* (White, 1967). White, a noted expert on the thought and technology of medieval Europe, pressed a case leading squarely to the need for deep religious reform as a necessary condition for any long-term solution to the massive environmental destruction that humankind, led by western civilization, is wreaking on nature.

White's argument begins by noting the enormous impact the human race has had, and is increasingly having, on the natural environment, from taming the banks of the Nile six millennia ago, to the recent Aswan Dam. By irrigating, overgrazing, deforesting, and the like, humans have changed the face of the earth from time immemorial. But now there is a qualitative change. Since the onset of scientifically-led technology, the impact of our race upon the environment has so increased in force that it has changed in essence (White, 1967, 1203).

Science and technology, having such explosive powers when combined, need themselves to be understood if they are to be controlled. The linkage between them is a striking historical phenomenon, since for most of human history science was an elite, aristocratic activity and technology a lower-class function. Their recent marriage is the extraordinary outcome of the democratic revolutions of Western Europe, which, by reducing social barriers, tended to assert a functional unity of brain and hand (White, 1967, 1204). White continues: Our ecologic crisis is the product of an emerging, entirely novel, democratic culture. The issue is whether a democratized world can survive its own implications. Presumably, we cannot unless we rethink our axioms (White, 1967, 1204).

The first step toward this necessary rethinking, for White, is recognizing that science and technology as we know them are distinctly occidental. Though science has inherited much of value from other cultures, today, around the globe, all significant science is western in style and method, whatever the pigmentation or language of the scientists (White, 1967, 1204). Equally important, though less often noticed, is the fact that this leadership (especially in technology) is not a new phenomenon. In Western Europe, by 1000 AD, at the latest, water power was used in a variety of industrial processes besides grinding grain; within 200 years, wind power was harnessed

as well. The technologies of Europe did not excel those of other civilizations in delicacy but in power. Science, too, began to flourish in Western Europe much earlier than the more visible scientific revolutions of Nicolaus Copernicus (1473–1543) and Galileo Galilei (1564–1642). Eager translation of scientific texts from Arabic and Greek into Latin began in the late 11th century and gained momentum. By the late 13th century, Europe had seized global scientific leadership from the faltering hands of Islam (White, 1967, 1204).

How shall we account for this extraordinary (historically unprecedented) scientific and technological dynamism in Western Christendom? White proposes that the answer lies in the worldview of Christianity itself, particularly as interpreted by the theologians and applied by the peasants of Western and Northern Europe. In the terms of the section on religious polarities of immanence and transcendence, Christian exclusion of the sacred from immanence in nature freed Europeans to exploit the earth in unprecedented ways. White illustrates from the technology of plowing. Early plows, developed in Near Eastern and Mediterranean regions, where soil is light and dry, did not turn the sod but merely scratched it. Cross plowing was necessary, but two oxen were sufficient for such relatively gentle preparations for planting. In northern Europe, however, where soils are sticky and moist, another plow was invented as early as the seventh century. It was

> equipped with a vertical knife to cut the line of the furrow, a horizontal share to slice under the sod, and a moldboard to turn it over. The friction of this plow with the soil was so great that it normally required not two but eight oxen. It attacked the land with such violence that cross plowing was not needed, and fields tended to be shaped in long strips.
>
> (White, 1967, 1205)

This violence changed the relations between humanity and the soil in a profound and ominous way.

> Formerly, man had been part of nature; now he was the exploiter of nature. Nowhere else in the world did farmers develop any analogous agricultural implement. Is it coincidence that modern technology, with its ruthlessness toward nature, has so largely been produced by descendants of these peasants of Northern Europe?
>
> (White, 1967, 1205)

White rejects the idea of coincidence. What people do about their ecology depends on what they think about themselves in relation to things around them. Human ecology is deeply conditioned by beliefs about our nature and destiny – that is, by religion (White, 1967, 1205). The attitudes behind our current environmental crisis, encouraging exploitation of nature with no regard to non-human values is the residue of Christianity, White declares. Especially in its western form, Christianity is the most anthropocentric religion the world has seen (White, 1967, 1205). Victory over Druidism and other pagan religions of immanence turns out to have been double edged: By destroying pagan animism, Christianity made it possible to exploit nature in a mood of indifference to the feelings of natural objects (White, 1967, 1205). Linking such attitudes to a passionate interest in natural science, motivated by a desire, as was often said, to think God's thoughts after him, meant that modern western science was cast in a matrix of Christian theology (White, 1967, 1206). That theology was one of transcendence, not immanence. Thus White draws the following conclusions:

> first, that viewed historically, modern science is an extrapolation of natural theology and, second, that modern technology is at least partly to be explained as an occidental, voluntarist realization of the Christian dogma of man's transcendence of, and rightful mastery over, nature. But, as we now recognize, somewhat over a century ago science and technology – hitherto quite separate activities, joined to give mankind powers which, to judge by many of the ecologic effects, are out of control. If so, Christianity bears a huge burden of guilt.
>
> (White, 1967, 1206)

Assessing guilt is one thing, suggesting solutions is something else. White does not believe that superficial approaches to environmental concerns, mechanical or cosmetic clean-up fixes, will suffice, in view of the depth of the origins of these problems. But even science and technology, given their attitudinal and ideological makeup, are weak reeds. More science and more technology are not going to get us out of the present ecologic crisis until we find a new religion, or rethink our old one (White, 1967, 1206). To this end, White proposes that we ponder the greatest radical in Christian history since Christ: St. Francis of Assisi . St. Francis was a Christian who emphasized immanence.

> The key to an understanding of Francis is his belief in the virtue of humility – not merely for the individual but for man as a species. Francis tried to depose man from his monarchy over creation and set up a democracy of all God's creatures.
>
> (White, 1967, 1206)

He held a belief in animal souls: souls with intrinsic value and worthy of religious salvation.

> His view of nature and of man rested on a unique sort of panpsychism of all things animate and inanimate, designed for the glorification of their transcendent Creator, who, in the ultimate gesture of cosmic humility, assumed flesh, lay helpless in a manger, and hung dying on a scaffold.
>
> (White, 1967, 1207)

With this in mind, and in the conviction that we shall continue to have a worsening ecologic crisis until we reject the Christian axiom that nature has no reason for existence save to serve man (White, 1967, 1207), White proposes that Francis of Assisi should be the patron saint for ecologists.

Theological response to White's critique was voluminous, and at times sulphurous. There is no need here to

cover the blow-by-blow reaction of Christians to the ideas outlined above, but various general positions can be identified. It is at least controversial, for example, whether St. Francis is such a supporter of immanence as White claims. Are entities in nature sacred in themselves or simply as precious as gifts from God? Often such arguments are not so much direct refutations of White as meditations on Christian spirituality in relation to nature: meditations expressed in the context of a new sensitivity to environmental concerns stirred in the 1960s and focused by the Lynn White controversy.

One position, taken by Cox (1966), preemptively celebrated all that White deplored. Cox embraced and welcomed the secularization of nature represented by Judeo-Christian desacralization of the sacred groves. In so doing, he recognized that the environment would lose a measure of protection, at least for a time.

> Yahweh, the Creator, whose being is centered outside the natural process, who calls it into existence and names its parts, allows man to perceive nature itself in a matter-of-fact way. It is true, as some modern writers have pointed out, that modern man's attitude toward disenchanted nature has sometimes shown elements of vindictiveness.
>
> (Cox, 1966, 20)

But this vindictiveness is a passing phase, Cox argues, and should not be seen as a necessary part of mature secularization.

> Like a child suddenly released from parental constraints, he [modern man] takes savage pride in smashing nature and brutalizing it. This is perhaps a kind of revenge pressed by a former prisoner against his captor, but it is essentially childish and is unquestionably a passing phase.

The norm, rather, is quite different. The mature secular man neither reverences nor ravages nature. His task is to tend it and make use of it, to assume the responsibility assigned to the man, Adam (Cox, 1966, 20).

Since this was written shortly before the publication of White's essay and cannot be taken as a direct answer to it, Cox does not attempt to deal with the long, historical time frame of domination alleged by White. On its defensive side, his position is more focused on recent, obvious violence done to nature, by the union between secularized theory and practice that marks late modern western civilization. But, in addition, Cox launches an offensive, in keeping with the ancient prophetic stress on social rather than environmental concerns, against ancient and modern terrors created by the illicit sacralization of anything natural. This means that:

> we should oppose the romantic restoration of the sprites to the forest. It may seem pleasant at first to reinstate the tribal spirits, but (as Hitler made all too clear) once the Valkyries return, they will seek a bloodthirsty revenge on those who banished them.
>
> (Cox, 1966, 31)

Interpreting destructive environmental attitudes as simply the passing product of human immaturity makes no use of the Christian doctrine of sin, which could, if deployed here, account both for the human tendency to ravage nature and for the revenge of the Valkyries. An alternative position to Cox's, making sin central, does just this. The French social critic and theologian, Jacques Ellul, has long condemned technology (Ellul, 1964). More recently, in the midst of the Lynn White controversies, though not in direct reference to it, Ellul returns to the theological fundamentals of the human relation to nature (Ellul, 1984). The relation, he argues, was intimate and free in paradise, but after the primal fall of humanity into sin, the relation to nature is in all respects distorted and under the rule of necessity. Both concern for the earth and concern for social justice are of equal importance to God.

> The comparison reveals how much God loves creation with all that it includes, its variety, its blossoming; and it means that the ecological destruction is of the order of sin: as considerable as war, genocide, the exploitation of man by man, injustice. There is no scale of sin; there is only the immensity of the love of God from which man claims to escape, the love which still endures for this creation that we ravage.
>
> (Ellul, 1984, 152)

And ravage we must. For Ellul,

> it is impossible to detach the relationship of man with the world from his relationship with God. It is no accident that from the moment when man challenged God (the 18th century), the technique of exploiting the world has taken off. It is no accident that the place where man decided that there was no God and that nature was purely natural is the place where the exploitation of the world developed (the west).
>
> (Ellul, 1984, 153)

Since God and scientific technology are mutually incompatible,

> conversely, it is no accident that the first great goal of the science oriented toward technology was to shake off the restrictions of divine tutelage. The effort to affirm science by itself, without limit, as judge of everything and carrying its own legitimization *inevitably* involved, as the other side of the coin, the devastation of the world, the squandering of possibilities, the frenzy of destruction.
>
> (Ellul, 1984, 153)

The faithlessness of Jews and Christians, who were in a position to understand this and respond with repentance by setting limits to human aggressiveness, has sealed the world's fate. It means that they, and they alone, are responsible before God, for the disaster in which we are beginning to live (Ellul, 1984, 154).

Ecological disaster, an inevitability for Ellul, may indeed be in store, say other theologians, but perhaps a middle way averting disaster can be found: a way in which humanity can

play a more positive role tending the Earth with constructive rather than destructive interventions. The stain of sin, no matter how deep, must be balanced by the readiness of God to redeem any situation, no matter how bleak. For Egbert Schuurman, a Dutch theologian, only this additional assurance makes the Christian message a Gospel, good news . God's grace holds the key to human repentance. This means that the stubborn pride that currently distorts human attitudes toward nature and society can at any moment be melted and a new order instituted. Humans need above all to pray for a widespread change of heart. Guided by the right motive, man in his cultural activity can be a blessing for nature (1 Kings, 4:33–34) and at the same time enter into an open way toward the future (Schuurman, 1984, 117).

Theologians of this middle way, regarding the proper human attitudes and actions on Earth may not look to St. Francis as the patron, as Lynn White suggests, but may prefer another outstanding figure in Christian history, St. Benedict. St. Francis celebrates unity with nature, but an ideal Franciscan democracy of all God's creatures allows little scope for the sort of human leadership, manipulation, and control, that complex civilization requires.

> Compared with St. Francis's deep feeling and sense of union with the natural world, St. Benedict's response was more practical, using nature with care and respect. The Benedictine monasteries combined work and contemplation. They developed sound agricultural practices, such as crop rotation and care for the soil, and they drained swamps and husbanded timber all over Europe. Benedictines were creative in practical technologies related to nature.
>
> (Barbour, 1980, 25)

PHILOSOPHICAL POLARITIES OF EXCLUSION AND INCLUSION

It is all very well for theologians to debate whether the natural environment should be regarded with respect, reverence or brotherly love, but if there are no fundamental categories available for general public understanding of how natural objects can be thought to have value at all, then the link between spiritual guidance and public policy is severed. This has been the case for most of the modern period. The outstanding philosophers of the age have tended to exclude values from any firm locus in nature, and the civilization whose modern conscience and institutions were shaped in the general worldview of its intellectual leaders reflects this exclusion in its practices.

Two feuding philosophers, both founding fathers of the modern worldview, agreed on little else, but did close ranks against the possibility of values subsisting, in any way, in nature. Thomas Hobbes (1588–1679) was a monist, a materialist who denied that the human soul is anything more than the reverberations of fine atoms; Rene Descartes (1596–1650), in contrast, was a dualist who held that the soul is absolutely immaterial and free from contamination by material categories. Both, however, accepted the distinction, propounded earlier by Galileo Galilei, between primary and secondary qualities. The former, primary qualities are the properties of natural objects open to mathematical description, such as size and shape, weight and momentum, location and motion. These are held to be characteristics, actually belonging to the thing in itself. Since they can be quantified, they can be grasped with precision, understood objectively. The latter, secondary qualities are the colors, smells, tastes, sounds, and feels of things. They are changeable, relative to the setting and the condition of the perceiving organism. They cannot be quantified but can be described only vaguely by eliciting subjective memories not everyone shares. They are the source of countless illusions, optical, auditory, and tactile. In extreme cases they obviously do not belong to things but are merely in the perceiver.

Galileo gives as an example the capacity of a feather to tickle. For some people it may have great tickle-power, but that is to say something about the people, not the feather. Now this tickling is all in us, and not in the feather, and if the animate and sensitive body be removed, it is nothing more than a mere name (Galileo, 1954, 86). But for Galileo, Hobbes, and Descartes, and through them for most modern philosophy, this same dependence on the presence of our animate and sensitive body is manifested by all the sensory qualities. As Galileo put it, Of precisely a similar and not greater existence do I believe these various qualities to be possessed, which are attributed to natural bodies, such as tastes, odors, colors, and others (Galileo, 1954, 86). From this comes the first of the great cliches that virtually every school child has learned from modern philosophy: If a tree falls in the forest and no one is there, does it make a sound? The standard modern answer, of course, is no . Physical vibrations in air and earth will be caused, but without ears and minds to translate those quantifiable vibrations into qualitative crackles and thumps, there is no sound, strictly speaking.

But if the hues of autumnal leaves are not really in nature but only in animate and sensitive lookers, and if the tones of birds are not really in nature but only in animate and sensitive listeners, then how much more obviously subjective must be the feelings of approval and enjoyment that human beings experience while looking and listening within their environment! From this comes the second modern philosophical cliche: Beauty is in the eye of the beholder . This saying can, and must (in this philosophical framework) be generalized to all values. Just as beauty is generated by human appreciators, so must goodness be generated by human judges, and truth be generated by human thinkers. Nature itself possesses no such values. It is odorless, colorless, soundless and tasteless

in itself. The gardenia's smell, the sunrise's hues, the brook's burble, and peach's flavor are dependent on human presence. Therefore, it makes no sense to preserve them from human exploitation or even to respect them along with humans. It is conceptually unthinkable for them to have intrinsic value apart from humans; it would be sheer philosophical confusion to imagine that they could have standing against human interests, could be addressed with reverence, or treated with brotherly love.

The immense prestige of the mechanical world picture created by Isaac Newton (1643–1727), which incorporated these key assumptions on the exclusion of qualities, values, and experience from the basic stuff underlying the natural world, greatly reinforced earlier views on the inert, intrinsically valueless character of nature in itself. This exclusionary world picture was then brought to its logical climax in the philosophical explosion lit by Immanuel Kant (1724–1804), who gave powerful deductive arguments for the absolute separation of the world we experience, the world in which we live and in which science works, from the world as it is in itself. Freedom, morality, knowledge, God, our own true selves (everything that is genuinely valuable) resides in the latter realm, which Kant called the *Noumenal*. Whatever can be experienced or even positively thought belongs to the realm of appearance, which Kant called the *Phenomenal* (Kant, 1966). Dignity is deserved only by moral agents, in Kant s view, and such agents must exclusively be rational, since morality itself consists in willing actions out of respect for moral lawfulness, and moral laws can only be recognized and obeyed by rational beings. Nothing in nature, therefore, can have dignity or (on the opposite side of the coin) rights. If we refrain from shooting an old, faithful dog which has served us well, it is not because the dog has a right to a comfortable retirement, for the dog cannot judge , but because we should cultivate tender feelings as part of our duty to humanity (Kant, 1963, 240).

Later, in the 20th century, philosophers convinced by Kant (and the main thrust of modern philosophy) that rights-language has no place in connection with natural things, but unpersuaded that it is any more possible to demonstrate by reason alone the foundations of morality even among human beings, dismissed all values as mere emotional expressions of preference and aversion (Ayer, 1946, Chapter 6). On this view, such sayings as nature is intrinsically valuable or we should all respect the dignity of nature are literal nonsense. There is no way to verify or falsify such utterances if they are taken as attempting to make claims about matters of fact that could possibly be true or false. Any and all experienceable facts would be equally compatible with them. But if taken instead as expressions of a speaker s feelings of warmth toward nature or a wish that others might share such attitudes, the utterances can be seen to have a function. What they do not do, however, is describe anything about nature itself, which stands extralinguistically as a vast realm of actual or possible appearances capable of con rming or confuting our hypotheses, and nothing more.

Despite enormous differences in thought-worlds, interesting similarities link this recent philosophical view of nature to Plato s in the fourth century BC. Things and the appearances of things are low on the hierarchy of values for Plato (c. 428 348 BC). When sense experiences can be uni ed into formal concepts of things, and concepts can be linked into theories (mathematical and otherwise) of increasing inclusiveness, there is a corresponding rise in worth, for Plato, both epistemological and metaphysical. The natural world of constant change ranks only on the lower order of mere becoming; the intelligible Forms that give understanding, in contrast, qualify for the higher order of true being: changeless, eternal, beautiful. Finally all are ideally uni ed through the supreme form of the good. Finite things are not valuable in themselves as changing particulars bound to the cycles of generation and decay, but gain value only to the degree that they exemplify the eternally perfect forms that give them meaning.

Plato s rmly exclusionist position, locating all genuine value outside nature in a higher, immaterial domain, was an easy t for Christian doctrine in need of a philosophical framework. There are Platonic themes inside the New Testament itself, especially in the Fourth Gospel, and during the rst three centuries AD, the early Church Fathers found the transcendence motifs of Judeo-Christian traditions hospitable to Platonic interpretations (Wolfson, 1970). Here, as noted in section one, no immanent sacredness in groves, neither Greek nor Druid, could nd legitimacy. The interplay between Christian spirituality and Platonic philosophy dominated European consciousness for more than 1000 years, encouraging other-worldly attitudes where ultimate values were at issue, bifurcating nature into a picture album lled with iconic reminders of eternal realities, on one level, and a mere warehouse for human exploitation, on the other.

The exclusion of value from nature is the lead story of western philosophy, dovetailing nicely with the transcendence of value in dominant western spirituality. Still, there has all along been an undercurrent of dissent, not only in religion (as in St. Francis), but also in philosophy. Plato s most distinguished student, Aristotle (384 322 BC), dissented at once. Instead of banishing value from the substances in nature to an independent realm of eternal forms, Aristotle proposed that we understand natural things as the inextricable combination of forms with individualizing, spatially locating matter, a hylomorphic (matter form) way of including all that Plato found valuable, but fully within the burgeoning domain of change. Living things can then be seen as working out their own internal Forms, their natures or essential characters. Their intrinsic teleology

(explanation of something in terms of the purpose it serves rather than in terms of its causes) can be fulfilled or frustrated. A tree can be chewed down before it has a chance to bear fruit, but a beaver can use its trunk and branches to build a dam in which to house and nurture precious offspring. Nature is a domain of competing and cooperating cycles of individual subjects of lives with intrinsic ends, norms of development, experiences, and satisfactions. All living things, for Aristotle, have souls, understood as the functioning of their innate characters, or forms. Plants have the powers of nutrition and reproduction and thus have vegetative souls; animals have these powers with the additional capacities of locomotion and sensation, giving them sensitive souls. Human beings have all the previous functions plus the conscious abilities to calculate and reflect, which is what is meant by *rational souls*. In every case it is the whole organism that is functioning in the ways characteristic of its essential nature: matter and form working together. Particular beings do not merely exemplify something higher, but manifest and embody the values of their forms concretely.

Aristotle's dissent from Plato was lost to Europe for the first millennium of Christian history, but it had been kept alive in Muslim thinking, and during the 12th century it was recovered by the West. This recovery, and its assimilation in the 13th century through the work of great scholastics like Albert the Great (1200–1280) and St. Thomas Aquinas (1224–1274), severely shook Platonic orthodoxy, but Aristotelianism prevailed, overwhelming the universities of the 14th and 15th centuries with the power of its new synthesis. Unfortunately for Aristotelian inclusionism, however, the very success of its worldview lured it into triumphalism. It became rigid and its science, scholastic in the familiar pejorative sense, the epitome of what modern thinkers like Galileo, Hobbes, and Descartes scorned as old-fashioned, reactionary word play. The value-excluding counterattack of modernity felt fresh and liberating in contrast.

Still, in modern philosophy, as a persistent undercurrent, value including positions were voiced despite the inhospitable climate. Baruch Spinoza (1632–1677), in lonely isolation, worked out a brilliant counter to the dualism of Descartes and the materialist reductionism of Hobbes. His solution was to find God in nature and nature in God, a pantheism in which everything should be considered to have infinite attributes, of which mind and matter are only two; though two of great importance to human beings. Nature, comprising all there is or could be, should be seen both as determined and created, *natura naturata* (nature natured), and as free and self-creating, *natura naturans* (nature naturing). In both respects, every manifestation of nature is a mode of manifestation of the underlying divine substance, the infinitely perfect one. Spinoza, having been expelled from his synagogue and enjoying few academic connections as a lens grinder, left no disciples, though his thought gained popularity in the 18th and 19th centuries among romantic and counter-cultural thinkers like Johann Wolfgang von Goethe (1749–1832) or Samuel Taylor Coleridge (1772–1834).

Gottfried Wilhelm von Leibniz (1646–1716) also argued against the grain of dominant western philosophy for an inclusionist position that took a very different shape from Spinoza's. Leibniz, a universal genius who invented symbolic logic and co-discovered the calculus with Isaac Newton, developed a highly pluralistic worldview in which the elements of everything in nature are to be seen (as in Spinoza's universe as a whole) with dual aspects of materiality and mentality. These ultimate *monads* (any elemental unit, like a soul) have experience and value, even if only dimly, for themselves. There are many different grades of monad, including human consciousness but in principle stretching high above and far below throughout the universe of things. Each manifests its own internal essence, much as Aristotelian living substances do. On Leibniz's theory of substance, there can be no direct relations among the monads, but all are coordinated by the creator God, whose perfection entails that only the best one of all the possible worlds that might have been created was actually realized. Leibniz in his time made few disciples. Excluded from the intellectual establishment represented by the Royal Society of London, he, too, had to await the 19th century for rediscovery and appreciation.

Other philosophers, notably Georg Wilhelm Friedrich Hegel (1770–1831) and Henri Bergson (1859–1941) labored to develop conceptual frameworks, in which nature could be thought to include its own rich palette of values, and these philosophers and others developed strong followings, especially outside the circles of thought in which the methods and presumptions of modern science are taken for granted as authoritative. But these have always been views struggling to breathe in the atmosphere created by modern western culture, whose dominant religion, science, and mainstream philosophical tradition all work to smother ways of thinking that would include values directly in nature. The western industrial machine, if it is to be countered or transformed by modes of thought and spirit, has not yet met its match.

BALANCING THE POLARITIES

Although machines are the embodiment of ideas and attitudes, knowledge and goals, it is true that once they are embodied, they are not easily stopped by ideas and attitudes alone. So it is that the rapacious western industrial machine, now worldwide, is likely to require a special convergence of circumstances, both physical and mental, before it can be tamed to the requirements of environmental good citizenship. In part, this convergence actually began in the latter part of the 20th century, when industrial civilization began to choke on its own runaway excesses. Pollution of

air, soil, and water, depletion of nonrenewable resources, desecration of precious beauty, distortion of social fairness between have's and have-nots: all these can be seen as plainly predictable outcomes of the modern system, not flukes, and thus they urgently require rethinking of the ideas, and adjusting the attitudes, that went into designing the industrial machine in the first place. In this spirit Lynn White cast around for an alternative religious hero for Christians, offering St. Francis as inspiration. Had there been no environmental crisis, no pollution disasters, no species extinctions, no fears of still greater horrors ahead, there would have been no need to search for blame or to seek new spiritualities. But practical exigencies have in fact arisen, preventing reliance on the *status quo*. They call in question even powerful orthodoxies, which in the absence of crises might have remained unchallenged. The prestige of science and technology, now recognized as contributing to the problem, is not enough to quiet the challenge. Something profound has gone wrong. Perhaps the atmosphere of the 21st century may be more hospitable to deep ideational reforms offering more comprehensive thinking, finer spirituality, and healthier ways of conducting practical life on the Earth.

The practical cash value of the polar clash between religions of transcendence and those of immanence comes down to the question whether the human race should conduct its business with nature as from above or from within the environmental order. The spiritualities of transcendence offer justifications for the former; spiritualities of immanence provide support for the latter. Each speaks with power to shape attitudes and policies. Is there any hope of finding a position of balance where the dynamics offered by the two poles can both be incorporated? Such balance has not often been sought. Even if this position were to be found, actual religions would need to make potentially painful internal adjustments to incorporate it. But perhaps the urgencies of the present historical situation could make the early 21st century an era of rare openness to just such religious growth and change.

Doing justice to the deep intuitions supporting human transcendence over nature without opening the door to heedless species chauvinism should be possible if actual human capacities are affirmed without indulging in the prejudicial snobbery that has too often distorted the affirmation. Human beings actually are different in profoundly significant ways from anything else found in nature. Nothing else in the known natural universe can approach human capacities for conceptual freedom. Normal adult humans can manipulate linguistic symbols to take account of possible or actual states of affairs far remote from actual circumstances. Language allows humans to consider distant places (across the mountains) and remote times (when Grandfather was a little boy , or next spring, at planting season) and weave detailed tapestries of thought out of insubstantial ideas. This capacity allows the development of long-term purposes and the fashioning of implements designed to achieve them. In this quite obvious way, human beings transcend the here and now of nature. Even highly intelligent non-human species do not come close to exhibiting human freedoms of dealing thoughtfully with what is not real and may never be real. In fact, one of the crucial ways in which humans use their transcendence over nature's *here-and-now* is to prevent the actualization of unpleasant possibilities envisaged in thought and therefore countered. An equally crucial way of using transcendence is by long-range planning of complex desired outcomes that could never have become real without the steady application of purpose.

Dreaming of distant futures and choosing between them, effectively harnessing present resources to achieve ideas and actualize outcomes: these are the basis for another sort of transcendence of nature, the transcendence of moral responsibility. Rocks slide and cause damage but are not responsible because they were only following the laws of physics and could have done nothing else under the given circumstances. Likewise predators kill but are not responsible. What they do is not deliberately chosen. Instincts refined by natural selection come into play as the animal responds, sometimes intelligently but always in ways restricted to the *here-and-now* of environmental circumstances. Human beings, in contrast, free to consider alternative possibilities in some detail and to choose which one to bring into actuality after (at least sometimes) extensive thought and sustained effort, transcend the rest of nature by carrying the burden of responsibility for outcomes deliberately achieved. The rest of nature operates by caused causes and cannot be blamed. Only human beings are influenced by norms and ideals (for better or worse) and can be held to account for their actions. If humans did not transcend nature in this way, there would be no point in appealing for improved environmental policies. One does not appeal to stratospheric ozone to reverse trends for the good of the climate, or urge deer to stop reproducing for the good of their habitat; but one may appeal to humans, on behalf of a larger envisaged good, to sacrifice some of their short-term interests or even to curb their appetites. And sometimes these appeals may be heeded, translated into action. Those who say that humans are no different from the rest of nature would in logic need to quiet their preachments. But of course preachments and appeals to conscience and ideals continue, appropriately, since humans do transcend nature in being morally responsible agents.

In these special capacities, for flying conceptually above the here and now, for taking account of the remote future and considering which of various envisaged possibilities should be realized, for implementing deliberate purposes, for knowing the self as morally responsible agent and as precious center of awareness destined to die, we discover the special joys and pains of personhood. The spiritualities

of transcendence, it seems, give voice to the justified awareness of the special value, the unique dignity, that goes with being a human person. So understood, this is far from a license to rape the rest of nature. It is, instead, the acknowledgment of special burdens and an invitation to unique satisfactions.

Though unique in these ways (the ways in which human beings are persons) our human species is by no means unique in the multitude of ways in which we are organisms. The spiritualities of immanence, stressing the intense and comprehensive values of immersion in nature, are obviously correct in stressing continuities and their profound importance. Our bodies, like those of most living species, both animals and plants, are sexually reproduced; and this is good. The fertility festivals and orgiastic rites of early religions of immanence celebrated the sacredness of nature's creativity, the urge to multiply and swarm, fructifying and filling every niche. Human bodies are made of meat and need nourishment. Metabolism reigns in us, as in all other forms of life. Food, water, air in adequate quantity and quality, are necessities for us as for all other living things in nature. The harvest festivals and hunting rituals associated with the spiritualities of immanence celebrate sacredness in domains of undeniably vital significance.

The Hebrew prophets, stressing the personalistic values above all (moral faithfulness, purity, justice) were offended by the organismic values they saw being venerated in prosperous agricultural Canaan. There were cultural and historical reasons for the revulsion of the prophets against the city-dwelling Canaanites. But there seems no logical requirement that we adopt the either/or attitudes they preached. Rejoicing in fertility need not be done unjustly, to the detriment of widows and orphans or against the interest of the powerless. On the contrary, acknowledging the continuities between our organic constitution and those of other animals, affirming the networks of relations between all animals and plants and the inorganic environment that supports the lives of all; these tributes to organicism are compatible with recognizing the unique values of personhood.

Perhaps, if we were to speculate about the spiritual and ecological needs of the future, we should try to work out a new position, we could call it personalistic organicism, a viable spirituality that could live creatively in the dynamic tension between the poles of transcendence and immanence. If we could establish such a point of balance, then ecologically sensitive moral agents, enabled to feel and appreciate vital natural connections between humanity and all other life forms (immanence) through uniquely powerful personal norms (transcendence), might be liberated to seek social and ecological justice without sacrifice of either aspect to the other.

This is not the place for the detailed working out of this project, which has been undertaken elsewhere (Ferre, 1996, 1998, 2001). There is no reason in principle, however, against hoping that the polar opposition between images of transcendence and immanence can be balanced in some yet more inclusive mode of spirituality. Can a synthesizing worldview, such as personalistic organicism, also hope to balance the theoretical tensions between the philosophies of exclusion and inclusion?

The great strength of philosophies arguing for the exclusion of values from nature has been the argument from the necessary subject-dependence of value. Beauty is in the eye of the beholder , or some variant of this modern mantra, is hard to deny. What could beauty be, if entirely divorced from the possibility of any appreciator? Just as pain (or Galileo's tickle) makes no sense apart from subjective awareness, so beauty and like values cannot be understood without ultimate reference to some center of appreciation or valuation. No purpose without a purposer; no love without a lover; no value without a valuer. Values have to be valued by some valuer to be real. The case is strong. Objective circumstances may be perfectly suited for grounding a joyful experience of beauty, but if the experience never occurs, those unrequited circumstances alone will not be enough to count as beauty itself.

This much can be agreed. Such agreement, however, does not force the conclusion that nature has no values of its own. The inclusion of values in nature can simultaneously be affirmed by expanding the scope of subjectivity. Kant was right in stressing the centrality of mind, but wrong in defining mind too narrowly in terms of rationality, in which human persons stand out from the rest of nature. Modern philosophy in its main tradition has been deeply but mistakenly anthropocentric in assuming that only human beings are subjects in the relevant sense of the word. No one present , in this constricted thought frame, tends to mean no human at hand. If the old saw about the tree falling in the forest were reframed, however, in terms of sentient organisms, there would be a much richer and more nuanced answer. Squirrels, bears, birds, rabbits, deer (perhaps spiders and earthworms, too) would detect the crash and react, each in its own way. Similarly, if subjects (defined as at least dimly aware centers of experience) were to be acknowledged throughout nature, there could be no doubt that qualities too are firmly woven into nature's fabric. Hummingbirds and bulls distinguish and appreciate the quality, red, in different ways. These appreciations, positive and negative, are facts about nature but also facts about how valuing is active in nature. Since butterflies and bees are drawn to attractive visual appearances and odors, for example, natural selection among flowers has run riot in sponsoring competitive beauty contests. Throughout – in the air, on the land, deep in the sea – the attractions and repulsions of positive and negative valuations are an obvious dynamic of nature.

Thus, since practical ethics finally rests on the felt obligation to show appropriate respect to quality and value, of

whatever kind, wherever found, a worldview recognizing subjective valuings beyond the human, will gain a firm basis for thinking through and proclaiming human duties, owed directly to entities in nature as well as to fellow human centers of value. Broadening the scope of subjectivity can balance the polarities between the truths of exclusion (only subjects, not inert objects, can ground value) and the truths of inclusion (subjects are everywhere). But this can happen only if the great divide, mistakenly fostered by Kantian anthropocentrism, is successfully challenged.

As one such challenger, personalistic organicism, stressing the continuities beneath the differences between entities in nature, will recognize alliances with other philosophies of continuity. Aristotle's stress on the innate teleologies of things, that they seek goods of their own and have their own fulfillments, will be an important insight to retain. Spinoza's and Leibniz's view that all things have internality, a mind-like character, will be another. Also alert to new data and theories, personalistic organicism will stress a postmodern physical understanding of the energetic, self-organizing universe that increasingly, through much of the 20th century, was revealed by science. Not the inert particles of Newton and Kant, but the dynamic wave-events of 21st century physics, interpreted as moments of extremely simple experience, will offer personalistic organicism an inspiring model for the basic elements of the vibratory universe (Whitehead, 1925). These, as they creatively wrestle actuality out of potentiality, are nature's minimum units of value, both in themselves and for others (Whitehead, 1976).

On such a postmodern speculative vision, responsive both to dynamic science and to balanced spirituality, a postmodern ecumenical dialogue is conceivable between religions and philosophies, East and West, on new ways to cooperate in the quest for social justice among persons and for moral consideration of the Earth.

Social Science and Global Environmental Change

STEVE RAYNER[1] AND ELIZABETH L MALONE[2]

[1]*Columbia University, New York, NY, USA*
[2]*Pacific Northwest National Laboratory, Richland, WA, USA*

The descriptive *tradition in the social sciences, which tends towards quantitative methods of tracing stocks and flows of social data through time and space, has been seen as more useful in mainstream global environmental research that relies on natural science methods and models. The* interpretive *tradition has been relegated largely to the sidelines, with its concerns to understand motivations, ideas, and values, and its frequent analytic focus on narrative and text.*

The descriptive approach derives much of its strength from simplifying assumptions about complex behaviors and tends to assume homogeneity of human responses to price signals. It therefore is often used for large-scale analyses. In contrast, the interpretive approach emphasizes variation and complexity, sometimes to the point of resisting simplification on principle. It therefore tends to produce local and disaggregated analyses. Descriptive researchers tend to see themselves as outside observers and to make utilitarian assumptions; interpretive researchers see themselves as participants in their studies and often assume individual rights-based ethics.

These are differences in kind that are both essential to research in global environmental change. For example, descriptive approaches have revealed much about what would happen under various scenarios of climate change, but interpretive approaches can provide value-related parameters as a basis for choosing among candidate policies.

Collaborative research that includes both descriptive and interpretive approaches has been carried out in studies of actual decision-making, which is a social-political process, not a rational, utility-maximizing one; and in mutual learning systems that incorporate models and negotiation. Further collaborations among researchers from both traditions and policymakers can help to bridge the current gap between industrialized and less industrialized countries, to expose assumptions that can improve decision making under uncertainty, and to make policy decisions more implementable and effective (see Box 1).

TWO STYLES OF SOCIAL SCIENCE

Social science in general is characterized by a long-standing gulf between two traditions or styles of analysis. One is the *descriptive* tradition, that identifies and traces stocks and flows of population, goods, services, wealth, and information, through time and space. Statistical modeling is an important tool in this approach. The other is the *interpretive* tradition, that seeks to understand the motivations, formation of ideas, sources of values, the creation and interpretation of information, and the development of shared understanding as the basis for the conduct of discourse and human actions in society. Focus on text and narrative is a frequent focus of this approach.

Because the two approaches are so different in kind, there has traditionally been little cross-fertilization between them. Models in both kinds of social science are simplifications intended to enable analysis of more complex cases. Simplifications tend to be more accepted in quantitative models; in qualitative models, they may be seen as mere stereotypes. Descriptive models, which tend to be mathematical or quantitative, are incomplete in that they cannot account for the full variety of behavioral variations among diverse human populations. Interpretive models, which tend to be verbal or qualitative, are also incomplete in that they are seldom capable of powerful generalization from case studies.

Public policy makers and private sector decision-makers tend to favor the descriptive style of analysis because it usually provides quantitative information that can be

Box 1 The Two Approaches to Social Science Analyses of Global Environmental Change

The *descriptive tradition:*

- Quantitative book-keeping of stocks and flows of social data
- Assumes homogeneity in human responses over large areas
- Models global change as a series of interconnected 'big' boxes
- Research agendas usually set by natural scientists

The *interpretive approach:*

- Emphasis on defining problems, rather than solving them
- Seeks to understand motivations, sources of values, interpretation of information
- Studies are most frequently undertaken at small spatial scales and results are often disaggregated
- Research agendas set by social scientists

represented as an objective basis for an organization s decision making, independent of the judgment of any particular decision-maker.

In the social science of global environmental change, the gulf between descriptive and interpretive approaches is exacerbated by the heavy reliance of global environmental science on models designed to represent the stocks and ows of resources and pollutants in an environmental medium, such as land, the atmosphere, or the ocean. These models can be made to interface with the models of economic growth and resource use that are typical of social science in the descriptive mode.

Opportunities for social science collaboration in major international scienti c research programs addressing global environmental change, such as the Intergovernmental Panel on Climate Change (IPCC), have been largely focused on extending the framework already established by the natural sciences. For climate change, that framework consists of a four-box conceptual model: quanti ed emissions of greenhouse gases, atmospheric chemistry, climate and sea level, and ecosystems. Within this framework (Figure 1), the social sciences provide highly aggregated data on human activities leading to greenhouse gas emissions. These data can be used to drive natural science models of global atmospheric chemistry and physics. In turn, the natural sciences aim to model climatic impacts on managed and unmanaged ecosystems upon which humans depend. At this point, social scientists are invited to project the outcomes of these changes for large-scale patterns of agricultural and industrial activity, stimulating macroeconomic and technological responses, which, in turn, may eventually alter anthropogenic emissions estimates. The outputs of such research are presented as data: grist to the decision-maker s mill. The same framework shapes the bulk of research undertaken within the international social science programs of climate and other global environmental change research, such as the Human Dimensions Programme of the International Social Science Council, which emphasizes stocks, ows and driving forces of change, particularly in relation to land use and the industrial metabolism of society.

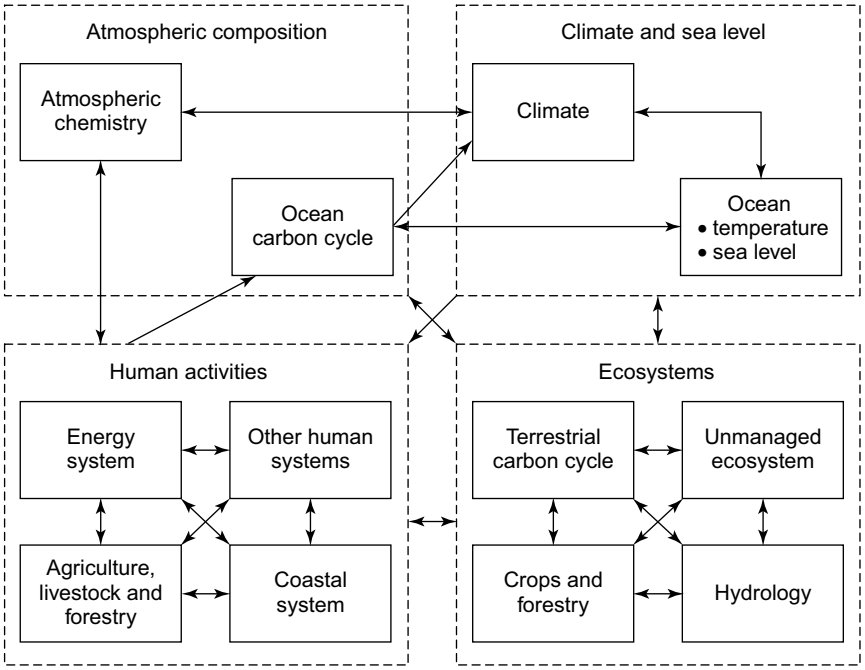

Figure 1 Elements of the climate change problem (*Source:* Watson *et al.*, 1996)

Even though the style of social science emphasized in these programs seems quite compatible with the cyclical framework postulated by the natural sciences, there has been significant concern about the issue of bridging the gap between natural and social sciences, a gap that is invariably taken for granted and associated with much hand wringing. Much is often made of the differences between the two intellectual traditions, exemplified in the distinction between the experimental tradition (including bench or laboratory science) and the study of human nature and the history of ideas.

The comparisons inevitably find the social sciences wanting with respect to the characteristics of theoretical consensus about fundamentals, measurability and phenomena and computability of relationships among them, and precision and accuracy of prediction. The explanations for these differences range from the charitable observation that social behavior is inherently more complex than the behavior of natural systems to the less charitable assertion that the social sciences are younger and, thus, less mature than natural science.

Since Snow's (1959) classic essay on the two cultures, we have become accustomed to the idea that the intellectual landscape bequeathed to us by the Enlightenment is bisected by a major fault line. But, the most significant fault does not, in fact, fall between the natural and the social sciences. Indeed the conceptual and methodological approaches of modeling the behavior of demographic and macroeconomic systems are essentially indistinguishable from those employed to model changes in the atmosphere or in ecosystems. The significant intellectual rupture falls right in the middle of the social sciences, one side of which blends seamlessly with natural science while the other side ultimately merges into the humanities. In debates about global environmental change, this rupture means that some social science research has been used while other research, though relevant and potentially useful, has not been employed in either formulating the issues or addressing them.

THE DESCRIPTIVE APPROACH

The descriptive approach primarily uses inventories and accounting systems for the stocks and flows of people, money, raw materials, commodities, and pollutants. For example, Figure 2 depicts human driving forces, land use, and land cover as discreet units that interact with each other in much the same ways that software modules interact. The descriptive tradition in social science derives from the empirical philosophy underlying natural science descriptions, specifically Newtonian science. Newtonian science is based on the belief that the mind learns everything from what is evident to the senses. English empiricist philosophers, following Locke (1623–1704), postulated that the human mind is a *tabula rasa* (clean slate) upon which the external world is accurately reflected (Locke, 1690). The radical empiricist David Hume (1711–1776) claimed that all knowledge derives from sensory experience. It has become almost a cliche to observe that Hume's philosophy is a Newtonian science of Man. Newtonian thermodynamic determinism is the background of the descriptive tradition in the social sciences.

This approach developed among scholars concerned with wealth, trade, and population in the century following Newton's (1642–1724) formulation of the laws of thermodynamics and Harvey's (1578–1657) description of the circulation of the blood. Indeed, Francois Quesnay (1694–1774), the key figure among the physiocratic economists of prerevolutionary France was also the royal physician. He drew explicitly upon Harvey's physiology in describing the economy. His *Tableau Economique*, published in 1758, is generally considered to be the first schematic description of an entire economy. The physiocratic models departed from previous thinking about the economy in that they did not invoke human choice, desire, and intention to explain the behavior of the economic system. Instead, attention focused on the characteristic operations of the system, i.e., what can be observed and measured.

A generation later, Ricardo's (1772–1823) model of the economy also elides human intentions (Gudeman, 1986, 45). His concept of the individual is not explicitly elaborated, but the actors in his model, whether landowners, capitalists or laborers, lack intentionality. Ricardo's view of the human is exemplified by his difference with Malthus (1766–1834) over Say's Law, according to which supply creates its own demand. For Malthus, demand is not a mechanistic response to supply, because it is made up of both the power and the will to purchase. But Ricardo (1814, VI : 133), foreshadowing the declaration of the apocryphal Madison Avenue advertising executive, If we make it, they'll buy it! maintained that the will is very seldom wanting where the power exists . Variable tastes and changing desires were not part of Ricardo's image of the human. Ricardo's model moved even further away from concern with human intentions than those of the physiocrats by his use of a mathematical schema, which emphasizes form at the expense of content. After Ricardo, economic models took on the mechanical characteristics of closed thermodynamic systems or mass-balance equations.

Following in the steps of the physiocrats and Ricardo, the descriptive approach relies heavily on the ability to count, weigh, and measure things such as numbers of people, industrial productivity, or degrees of wellbeing. This aspect has led some commentators (e.g., Robinson and Timmerman, 1993) to describe the descriptive method as a physical flows approach. However, less tangible elements, such as beliefs and values, can also be represented in the descriptive method as counts of the number of people

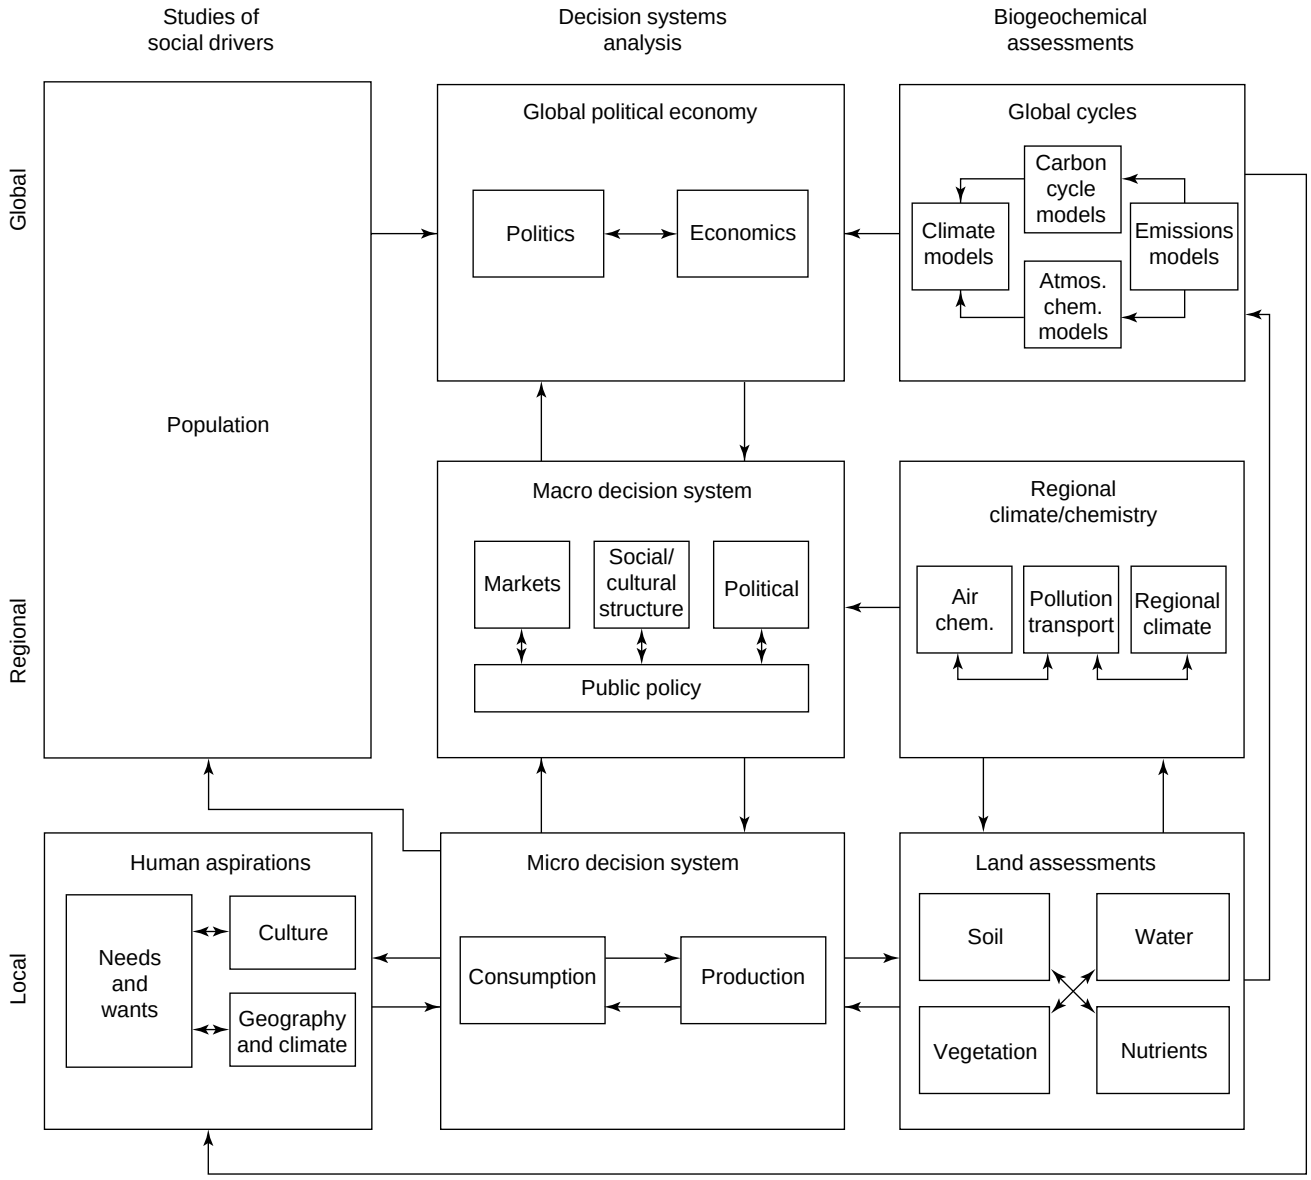

Figure 2 The stocks and flows approach of the descriptive paradigm (*Source:* Rayner *et al.,* 1994)

professing them, e.g., mass survey research or analyses of voting behavior. Knowledge and values converted to quantities in this way can therefore be accounted for as stocks and flows.

The descriptive approach has several advantages. The results of descriptive social science investigations are able to draw on the legitimacy of the natural sciences, by mirroring the scientific method and the thermodynamic paradigm. Counting and measuring can provide insight into the scope and severity of a problem or locate probable causes among many candidates. Descriptive analysis can compare various pathways from the standpoint of economic efficiency. Its simplifying assumptions and equations can lay out large problems and render them more tractable. And, finally, because the descriptive approach deals primarily with tangibles, it provides a basis for control; e.g., counting tons of fossil fuel used can provide a basis for a tax scheme that will limit the number of tons burned. This approach is typical of economics and demography as well as much of (American) quantitative sociology, behavioral psychology and quantitative political science.

The descriptive approach in social science and its pre-eminent place in policy analysis arose as part of the larger intellectual effort to devise technologies that could enhance the rational management of nature and society by the emerging modern state. Headrick (1990, 59) points out that, As early as the seventeenth century ••• (governments) encouraged the increase in knowledge of and power over

nature . Headrick lists examples, such as the patent system introduced in England in 1623 and the founding of scientific societies throughout the 17th and 18th centuries. This was the prelude to a massive increase in the rate of global resource extraction. He continues, Insofar as technology is knowledge of nature and how to manipulate it for human ends, it follows that countries with the most information are also the most able to develop their economies and transform the land (Headrick, 1990, 59). The social science technologies of the same period included the new field of statistics, which emerged in the mid-18th century as the practice of inventorying the resources of the state. Merchant (1990, 682) eloquently describes the contribution of the descriptive paradigm to the development of modern political, commercial, and industrial power:

> ••• When mapped by explorers and cartographers, catalogued and inventoried by militarists and computer scientists, ••• (nature) is controlled by an eye of power and subject to unlimited surveillance. Foucault's model of the panopticon of Jeremy Bentham, in which an entire prison can be surveyed from a single central tower, translates to the concept of a cultural overseer.

This stance has been variously described as the separation of the subject from the object, Man/Nature dualism, and instrumentalism. As Latour (1986, 29) observes:

> ••• we can work on paper with rulers and numbers, but still manipulate three-dimensional objects out there •••. Distant or foreign places and times can be gathered in one place in a form that allows all the places and times to be presented at once.

Thus, the descriptive tradition in both natural and social science separates us from nature and society while providing us with a significant level of control over them. For example, this power is highly concentrated in the computer models that we currently use for tracking materials flows and their consequences in both environmental science and macroeconomics, for example, general circulation models of climate and general computable equilibrium models of the economy.

Like all sources of power, this one comes with a price tag; separation of knowledge from the knower. The development of the modern industrial state relied on strategies of control, and modes of mapping, tabulation, recording, classification, and demarcation. These increasing levels of control over nature meant also increasing separation from experiences that should be part of the decision-making process. Faced with disembodied parcels of descriptive facts, decision-makers may become more and more isolated from experience of how myriad decisions transform production and consumption at the level of the community, the firm, and the family. For example, in debates about the cost effectiveness of climate change mitigation measures, the hardships of poor people in environmentally marginal areas (deserts, coasts) may be hidden in world gross domestic product (GDP) statistics. For climate change policies, this has been a source of the disjoint between cost effective strategies and effective implementation.

Furthermore, the descriptive method is epistemologically realist. The meaning of belief and value structures and the ways in which they are constituted, reproduced, transformed, and translated into action in social life are treated as unproblematic in this approach. Inquiry into these is firmly located outside of the descriptive method within what we refer to as the interpretive method.

THE INTERPRETIVE APPROACH

In contrast, the interpretive method focuses on understanding the meaning that human agents create in the conduct of social life, upon which they build their understanding of their world, and through which they seek to act upon that world. Thus the interpretive method focuses on the nature of experience, the structure of perceptions, the recognition of interests, and the development of frameworks for collective action.

Because these factors often elude quantification, the interpretive method has often been characterized as qualitative social science, contrasted with quantitative approaches that we describe as the descriptive method. However, we eschew this particular distinction between the two traditions for three reasons:

1. Interpretive social science need not be qualitative (some practitioners having devised sophisticated methods to quantify phenomena that are not as obviously susceptible to counting as heads or barrels).
2. The quantities in descriptive analyses are, in any case, often a numerical representation of a qualitative judgment on the part of the analyst rather than an empirical quantity.
3. The distinction between quantitative and qualitative measurement is actually rather fuzzy (for example, dresses may be sold as small, medium, and large or as sizes 2–16).

The distinctions between descriptive and interpretive approaches can be rather fuzzy, as well. In fact, within the interpretive approach a researcher can take data of all kinds, quantitative and qualitative, and make coherent meanings that can be used to devise workable arrangements, to effectively address problems, and to set up usable process frameworks. For example, anecdotal and case study evidence can be used to supplement or supplant statistical data. And, of course, the descriptive approach usually includes some interpretive analysis, e.g., in the discussion following the presentation of results and in the conclusions and recommendations of technical reports.

The interpretive tradition in social science emphasizes the essentially social character of the operation of the

human mind. The interpretive method is strongest in history, cultural anthropology, and (European) qualitative sociology. Interpretive analyses of various kinds of global environmental change have addressed the framing of the problem as well as issues of stakeholder involvement, sociocultural values, the nature and production of knowledge, and policy implementation (research and development investment, technology selection and diffusion, etc.).

The interpretive tradition derives from philosophical discussions about how human beings acquire knowledge and form (or are formed into) social structures. Although the interpretive tradition can be traced back to classical Greece, the modern interpretive tradition derives from Immanuel Kant s (1724 1804) disagreement with the English empiricists. Kant speci cally rejected the radical empiricist claims of Hume, that all knowledge derives from sensory experience, insisting instead that reason was itself a capacity of the human mind that shaped experience. Thus, in contrast with the descriptive approach, the interpretive tradition has always distinguished itself by its emphasis on human choice and intentionality. The mind s structuring of sensory experience derives from three sources: the physiology of the human nervous system, the unique historical experience of the individual, and the social and cultural categories and rules that are provided by language and by membership in a family and a larger community.

> Kant introduces a new conception of knowledge. Knowledge does indeed have as a source the Humean element of impressions, the sensory element in which the mind is passive •••. But Kant continues, there is another element in our knowledge, which is derived not from sensory experience •••. The second element comes from the mind itself. The human mind is not a blank tablet or an empty cupboard as the empiricists Locke and Hume claim. It is equipped with its own pure concepts by means of which it organizes the ux of sensory impressions into substances, qualities, and quantities, and into cause and effects.
>
> (Lavine, 1984, 193 194)

However, while seeking to avoid imposing a deterministic framework on the study of human choice, the interpretive social sciences, exempli ed by the philosopher and historian Wilhelm Dilthey (1833 1911) retained their commitment to provide systematic understanding of its manifestations.

> Dilthey wanted to uphold the humanist component of historical science without compromising ideals of rigor and objectivity. He thought of interpretation as a disciplined quest for orderly connections in an observable world; a way of doing science, not of escaping science. Yet he often expressed the difference between the human and natural sciences by drawing a sharp distinction between understanding and explanation: We explain nature, we understand mind .
>
> (Selznick, 1992, 76)

One of the primary foci of the interpretive method is the understanding of how humans draw meanings out of the data presented to them, emphasizing the sociocultural and institutional (including political) processes involved. The systematic study of such processes yields understanding that can help us make critical choices, knowing what assumptions and decision elements underlie those choices.

As Ryle (1949) suggested, thinking does not take place in the head, but all around us. What we think with is not a private metaphysical mind, but words, pictures, gestures, actions, and both natural and manufactured objects. Indeed we assign symbolic meaning so as to impose some sort of order and coherence on the stream of events. In so doing, we sift and lter our sensations of the world. Contemporary studies on the physiology of the mind (Edelman, 1994; Damasio, 1994) reinforce the physical basis for thinking that can be conjoined with individualistic and social/cultural theories of knowledge and action.

> In the process of making the whole business comprehensible, some perceptions are admitted, some rejected, and others combined or broken down. If we did not lter experiences in this way or make use of public symbols for organizing perceptions and communicating them to others, then we would be likely overwhelmed by the variety of possible interpretations that could be assigned to events. We would have to abandon intellect and discourse and thereby be forced, like the lower animals, to rely on instinct. Mankind would be reduced, as Geertz (1973) has observed, to mental basket cases .
>
> (Gross and Rayner, 1985, 3 4)

Different people, of course, organize and assign meanings to their experiences differently. Though we have the same general brain structures and turn our eyes to the same world, there are variations in what we see. As Kuhn (1970, 193) says:

> research shows that very different stimuli can produce the same sensations; that the same stimulus can produce very different sensations; and, nally, that the route from stimulus to sensation is in part conditioned by education. Individuals raised in different societies behave on some occasions as though they saw different things.

The interpretive method insists that no standpoint exists outside of history or of society from which either can be independently observed. All organized knowledge, by de - nition, depends upon socially construed conventions for its organization. In this sense, the interpretive method treats knowledge as having no objective existence. However, most interpretive social scientists use comparison of interpretations to generalize human behaviors.

STYLE AND SCALE

The descriptive approach derives much of its strength from simplifying assumptions about complex behaviors. It tends to assume homogeneity (or at least a tendency to homogeneity) of human responses to price signals. It

therefore is capable of high levels of aggregation in its analyses.

In contrast, the interpretive approach emphasizes variation in human motivation. It explores complexity, sometimes to the point of resisting simplification on principle, regardless of how useful or appropriate it might seem. Indeed, attempts to simplify within interpretive models are often criticized as stereotyping. The interpretive approach therefore tends to produce highly disaggregated analyses.

As a result of their different approaches to aggregation, the two kinds of social science tend to be comfortable at different extremes of scale. The descriptive approach tends towards large-scale analyses, with the nation state (which grew up with the descriptive approach) often accepted unquestioningly as the appropriate level for many descriptive analyses. The descriptive approach may be more suited to initial analysis of problems at the global scale; the stance of the observer and tendency toward aggregation can facilitate analysis at that level.

The interpretive approach, on the other hand, tends to focus on the local scale of face-to-face discourse. Here, the human individual is often regarded as being the natural, self-evident unit of analysis. It is often difficult to demonstrate the relevance of social science at this scale to global-level research agendas.

However, the case is frequently made Not only that the human activities that drive and mitigate environmental change vary significantly by region or place, but also that historical or local contextual factors are so influential that understanding must be grounded in the specifics of the case (Turner *et al.*, 1990, 18). In the last analysis, the activities that drive land-use change or anthropogenic greenhouse gas emissions are always local, and whatever the impacts of global environmental change on human populations, they will be experienced at the local level.

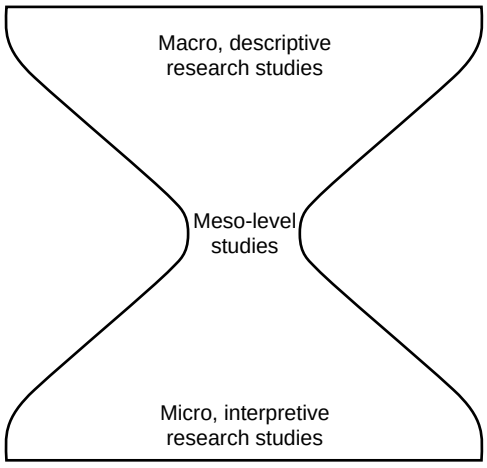

Figure 3 Social science research concentrated at macro and micro scales

The issue for the social sciences is not merely the assertion of the importance of local level analysis. As a result of the polarization of the descriptive and interpretive methods, research areas in the social sciences are shaped like an hourglass (Figure 3). That is, theories, methods, and data are underdeveloped at the middle scales between the individual and the nation state.

Furthermore, correspondence between the macro and micro scales is often treated in a simplistic way. The nation state or the firm is often treated as if it were one large individual, with a unitary intelligence and decision-making capacity. Or the resources of real individuals may be represented merely by dividing total resource by the number of people, resulting in the creation of a mere *per capita*; the anonymous average person from whom *per capita* statistics are derived.

> The image is of a male person, sometimes a homunculus inside each of us, sometimes a gigantic system incorporating the whole of society or the world. Our pervasive microcosm to whose outlines all our explanations are drawn to fit is a quintessential stranger; he has no family or friends, no personal history, his emotions are not like ours, we don't understand his language, still less his purposes.
>
> (Douglas and Ney, 1998)

For example, in the field of energy modeling, bottom-up analysts project individual behavior onto the national scale (one large individual) while top-down analysts assume that the behavior of individuals reflects that of the national population in proportion to their numbers (*per capita*). Although the names of the modeling approaches seem to indicate macro and micro scales, in fact neither approach is based on a theory of micro–macro scale articulation; both are descriptive approaches that assume undifferentiated individuals.

Local-level analyses, on the other hand, often focus on individuals and small, specialized institutions without regard to their generalizability (more studies are needed to determine whether similar results can be found in neighboring villages); or their generalizability is taken for granted, i.e., village level solutions are recommended for settings the world over.

Linking the local and the global is frequently cited as one of the most challenging aspects of climate and other manifestations of global change. Few attempts have been made to validate studies at one end of the scale with those at the other, and the research studies are sparse at the middle levels, especially those that articulate connections among individuals, groups of various sizes and cultural backgrounds, and global level players in global environmental change issues. From the perspective of the social sciences, meeting this imperative requires, as a first step, linking the interpretive and the descriptive approaches, using the research approaches and strengths of each, and expanding the reach of study, as appropriate, into various middle

scales, with appropriate integration of overlap. However, as discussed in the next section, the viewpoints cannot and should not be merged; each makes unique contributions to scientific knowledge.

STYLE AND STANDPOINT

Throughout the social sciences, there is poor understanding of the articulation of human behavior at the local level to the behavior of the global social and economic system. Furthermore, available knowledge of local behaviors has not yet penetrated very deeply into the global environmental change assessment and research agendas of the IPCC, the IGBP and the Human Dimensions Programme of the International Social Science Council.

Linking the local and the global cannot be achieved simply by increasing the scale and quantifiability of interpretive analysis to meet a more thickly textured descriptive analysis as it attempts to accommodate lower levels of aggregation. The gap between the two approaches is not merely spatial but raises fundamental issues of what kinds and sources of knowledge we value as analysts. Contrasting 16th century iconography with contemporary satellite photographs, Ingold (1993) illustrates the situation by tracing the change in the standpoint of human inquiry from the Enlightenment to the present (Figure 4). In Maffei's *Scala Naturale* of 1564, the scholar is shown at the center of the environment consisting of 14 concentric spheres envisaged to form a giant stairway, the ascent of which, step by step, affords more comprehensive knowledge of the world through experience within it. In modern satellite imagery, the scholar experiencing the world from within, is displaced by an observer viewing the world from without.

This descriptive standpoint favors observation over experience. Local (interpretive) knowledge, originating in experience, is downgraded as partial, parochial, and ultimately unreliable. Global knowledge is treated as universal, total, and real.

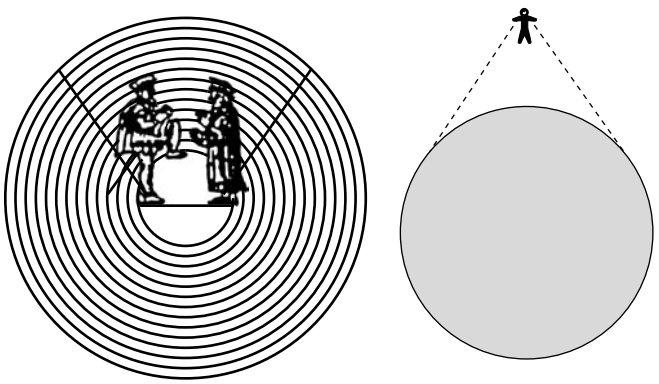

Figure 4 Local and global standpoints. (Reproduced by permission of Routledge in Ingold, 1993)

Against this view, Ingold argues that:

> The difference between them (local and global perspectives) is not one of hierarchical degree, in scale or comprehensiveness, but one of kind. In other words, the local is not a more limited or narrowly focused apprehension than the global, it is one that rests on an altogether different *mode* of apprehension; one based on an active perceptual engagement with components of the dwelt-in world, in the practical business of life, rather than on the detached, disinterested observation of a world apart.
>
> (Ingold, 1993, 40–41)

If the two standpoints are so different in kind, how can a potential for complementarity be applied to a global environmental change issue? The descriptive approach provides an absolutely vital link between the social sciences and natural science analyses of global environmental change. Collaboration between natural science and the descriptive approaches has revealed much about what would happen under various scenarios, but it does not help in choosing among the probable or feasible scenarios. To understand these issues, we also require interpretive approaches that can introduce qualitative and value-related parameters. For example, both approaches are highly relevant to current negotiations about how to implement the Framework Convention on Climate Change (FCCC).

The FCCC states that The ultimate objective ••• is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere that would prevent dangerous anthropogenic interference with the climate system . Further, policies and measures to deal with climate change should be cost effective so as to ensure global benefits at the lowest possible cost . A particular ceiling for greenhouse gas concentrations can be maintained in a variety of ways. Some will be more costly than others. Economic analysis in the descriptive tradition can show that it is more expensive for all nations to stabilize emissions individually than for the world to stabilize emissions jointly. But some regions might be better off under an individual stabilization scheme. Descriptive analysis can identify conditions under which high population countries would have an incentive to drop out of an international agreement to control fossil fuel carbon emissions in the post-2000 period, even if emissions rights were allocated on an equal *per capita* basis. Descriptive analysis can also highlight the need to construct dynamic international agreements, capable of being modified as global changes occur and societies evolve. But the descriptive approach cannot successfully explore social and ethical dimensions of different political options and has difficulty dealing with tradeoffs between equity and efficiency.

Redressing the disconnection in style, scale, and standpoint within the social sciences will at least require bringing together the descriptive and interpretive methods. Using and broadening established mechanisms, researchers can adopt

either a *multidisciplinary* or an *interdisciplinary* approach. In the former, scientists from various fields work together on a problem that has been defined within the framework of one particular discipline. A truly interdisciplinary approach involves people from different fields working on a problem that they have defined together in a way that it cannot be defined from within any single discipline. Interdisciplinary research often yields insights not otherwise attainable.

Perhaps the strongest reason for exploiting the complementarity between the two approaches is the nature of global environmental issues. The dimensions of global environmental change simply cannot be adequately addressed without using both approaches. Furthermore, strong linkages between the two can provide a further bridge to rich resources within the humanities that can also help to deal with fundamental issues such as social justice.

For example, the development of eco-feminism (*see* Ecofeminism, Volume 5) represents just one linkage between research in the humanities and social sciences, centering on an environmental debate. Arguments about the right relation between humans and non-human nature often have their basis in spiritual and moral values which rely on evidence from theology, moral philosophy, and literary imagery as much, if not more than, scientific data. Eco-feminism, which has been linked with neo-paganism (specifically, goddess worship), draws its rationale from a sociological critique of the twin oppressions of the domination of women and nature (Merchant, 1992, 185). Sociological, political, and image-rich arguments are blended, for example in *Woman and Nature: The Roaring within Her* (Griffin, 1978). Drawing on such diverse notions as the reconstitution of the subject and elemental divinity, Griffin and others seek to demonstrate the importance of women (and women's work) and non-human nature. Part of the pro-feminist argument revolves around the idea that women, as the carrier of children, are the first environment and thus have a special link with other nurturing systems in nature. Another part of the argument relies heavily on statistics about the type and value of women's work in agricultural and other economic systems.

LINKING SCIENCE AND HUMAN VALUES

At the human level, global environmental change is ultimately an ethical issue. Just as technical analyses and arguments prove insufficient to persuade communities to use imported technologies, human decisions about the threat of global environmental change are not merely technical. They are decisions about equity, what is fair in our relationships with each other and about natural ethics, what is right with respect to our relationships with nature.

While the analysis and description of ethical systems as social phenomena belong in the social sciences, the normative exercise of ethical reasoning is traditionally the province of philosophy and theology. Thus, bridging the gap between the descriptive and interpretive traditions in social science (and even exploiting the commonalties between interpretive approaches in the social sciences and the humanities) is an imperative for effectively linking the practice of scientific and moral reasoning in confronting global environmental change.

A further practical imperative to integrate the descriptive and interpretive methods is the need to understand human choice in social change as well as aggregating market behavior and mapping demographic change. Following in Ricardo's footsteps, the descriptive method assumes continuity of human preferences and consistency of human behavior over time. The descriptive models do not seek to explain the values that humans hold. They therefore cannot anticipate sudden ruptures in social behavior resulting from changes in values and the institutional arrangements that embody those values, or to assess the potential for changing human motivations through political or other forms of social intervention. Because a vast array of human behavior involved is effectively compressed into drivers and responses, the descriptive approach encourages the adoption of behaviorist kinds of explanations for the actions of social systems and the individuals within them. Hence, policy prescriptions based solely on the descriptive paradigm are limited to instrumental tinkering with technology and prices.

But, social systems involve human choice; unlike a billiard ball shot across a table or an electron orbiting the nucleus of an atom, a human being has the ability to make conscious decisions about the directions in which he or she is moving and at what speed. Although social decision-makers are often constrained by their own paradigms and the initial conditions of the problem they are attempting to resolve, the existence of human choice means that their actions cannot be accounted for in purely deterministic terms.

VALUES IN SCIENCE

Human choice also raises a methodological problem for the construction and operation of descriptive social science. Science, whether natural or social, is conducted by humans and is thus itself subject to human choice. Humans choose what to study and what to ignore, what methods to use in their analysis, and what criteria to apply in determining the validity of the data gathered. For instance, do we study energy conservation or geoengineering? Do we assess quality of life or longevity? Must we have an untreated control population or can we learn from studies that treat all subjects?

In making these choices, researchers and decision-makers inevitably make value judgments. However, when the value-based assumptions embedded in the theory or model

disappear into the background, they come to be seen as natural and are uncritically accepted, often without any conscious thought about either their presence or their implications. Indeed, the more that scientists reduce human choice within descriptive models, the more that they interfere as agents. Excluding human agency from applied social science research is itself a powerful and constraining assertion of the researcher s own choice upon society. Since we humans cannot stand outside of history and society to observe and describe them, we must use the insights of interpretive social science to make the underpinnings of our analysis as explicit as we can.

Interpretive social science brings to the conduct of scienti c inquiry an awareness of the impact of human choice, by introducing *re exivity* into the research and policy making processes. Re exivity is the self-conscious examination of the implicit assumptions that are inevitably embedded in any analytical approach. In the descriptive approach, assumptions may be systematically laid out but are typically unquestioned within the research study. This is consistent with the outside observer stance of the descriptive researcher. If, however, these assumptions are made explicit, the researcher has an opportunity to question them, rather than taking them as given. The interpretive contribution of keeping assumptions visible adds meaning to the research results by providing clear boundaries and caveats. Thus, if research in the two paradigms can be integrated, a more complete analysis can be accomplished.

The descriptive approach only works effectively when scientists take their assumptions for granted, so that they can structure experiments that will have meaning within those assumptions. Acting scienti cally means acting on the assumption of a determinate nature waiting to be described by a neutral observation language (Fish, 1994). In the natural sciences, Kuhn (1970, 163 164) notes:

> that once the reception of a common paradigm has freed the scienti c community from the need constantly to re-examine its rst principles, the members of that community can concentrate exclusively upon the subtlest and most esoteric of the phenomena that concern it. Inevitably, that does increase both the effectiveness and the ef ciency with which the group as a whole solves new problems.

Humans must reproduce and extend cultural conventions that are unquestioned in everyday life. As Alfred Whitehead has said in another connection,

> it is a profoundly erroneous truism ••• that we should cultivate the habit of thinking what we are doing. The precise opposite is the case. Civilization advances by extending the number of important operations, which we can perform without thinking about them. This is of profound signi cance •••. We have developed these practices and institutions by building upon habits and institutions which have proven successful in their own sphere and which in turn become the foundation of the civilization we have built up.
>
> (Hayek, quoted in Koford and Miller, 1991, 22)

However, while in daily life the ability to do more things with less deliberation may be a sign of technical and social development, it also increases the danger of unwelcome surprise. The interpretive social sciences have the capability to make the implicit explicit, to provide society with the tools of re exivity and to enhance society s resilience to shocks.

Combining the re exivity of the interpretive with the instrumental knowledge of the descriptive method seems an obvious course for improving our understanding of the human dimensions of global environmental change and use in policy making. A re exive social science drawing effectively on both the descriptive and interpretive methods could help identify the multiplicity of characteristics needed to achieve successful solutions, both immediate and longer term, associated with varying alternative global environmental management strategies.

SOCIAL SCIENCE RESEARCH AREAS IN GLOBAL ENVIRONMENTAL CHANGE

Global environmental change may not be the deciding factor in whether humanity as a whole ourishes or declines. The resilience of human institutions and their ability to monitor and adapt to changing conditions seems to be more important. Therefore, the social sciences have much to contribute towards illuminating issues such as pollution, climate change, and biodiversity. This section provides a brief discussion of issues taken up by social scientists in climate change research (Rayner and Malone, 1998) to indicate the breadth of social science contributions to global environmental change research.

Insight into how scientists choose to study global environmental change and how they form a scienti c consensus demonstrates the basis on which issues are taken up: and on what basis they could be taken off the agenda. To avoid promoting unrealistic public and policy-maker expectations of scienti c prediction and control over nature, the scienti c community thus must work for acceptance and public authority through patiently constructing communities of belief that provide legitimacy through inclusion, participation, and transparency.

Similarly, knowing why and how people decide that global environmental change is worthy of attention reveals the variety and roots of human values and concerns. Forms of social solidarity appear to be a crucial variable in shaping people s sensitivities to risk in general and threats to environmental and climate change in particular. Furthermore, equity is a crucially important issue, but at least three equity principles can be applied: proportionality, priority, and parity (Thompson and Rayner, 1998). Recognizing the broader debates inherent in environmental change issues (development is another) may allow policy makers to address a number of important problems concurrently.

Sorting out causal explanations and prescriptions for change puts the debates about environmental change in a new light and provides new ways of finding common concerns and areas of agreement. For example, in climate change debates different groups cite population, consumption, or the market as the villain; since all of these diagnoses are partial explanations, debates among groups can lead to stalemate. When confronted by such a dilemma, social scientists can examine alternative framings of the problem and solution that will be helpful in resolving the issues.

The rational-choice model of decision-making is an inadequate guide in global environmental change issues. Social science research can identify and delineate alternative decision-making frameworks that include quality and meaning issues. A broadly based framework may help to reveal win-wins that have been overlooked.

Resource management practices (for land, water, energy, etc.) are the immediate cause of environmental degradation. Social science research can describe the human activities that give rise to environmental concerns, identify possible mitigation actions, indicate where adaptations will be necessary, and illuminate how institutional and cultural structures and abilities to change will both constrain and open up possibilities to make and implement policy.

Social science research demonstrates that the process through which choices articulate across scales is not a linear mechanism that consistently produces the most rational alternative at the next highest scale. Rather, it is a social as well as a knowledge process that requires a high level of trust and agreement (including standardization of methods and results) to gain recognition at another scale. Research that describes choice processes is important; equally important is research that describes processes by which individuals can be persuaded to conform with new normative requirements of corporations and governments, as implemented by the decision-makers who are their officials.

ENVIRONMENTAL JUSTICE: UTILITY- AND RIGHTS-BASED APPROACHES

The descriptive and interpretive approaches embody quite different normative imperatives for decision-makers. The tendency of the descriptive paradigm towards high levels of aggregation gives rise to a top-down decision-making rationality. The quantitative aspect of the paradigm leads to an essentially utilitarian perspective on decision-making. That is, the practice of inventorying the stocks and flows of goods and bads creates the conditions for a decision framework based on a technique for calculating societal happiness measured by their distribution (Bentham, 1748–1832). The rise of *utilitarianism* as an explicit decision-making principle in the 18th and 19th centuries paralleled the development of systems of national accounting and statistics designed to assess and facilitate the development of industrial capitalism but which also held out the prospect of civil or corporate leaders being able to rationally assess the impact of decisions on the wellbeing of the statistical population.

It is but a short step to turn the possibility of such a means for calculating what would contribute to the greatest happiness of the greatest number into the imperative that one should pursue that goal. The solution that provides the greatest happiness of the greatest number also must be an efficient solution, since any departure from efficiency, also by definition, reduces the amount of good available for distribution. A bias toward the value of efficiency is inherent in the methods of policy analysis and utilitarianism has been the ideological position most forthrightly incorporating this standard as a central value (Heineman *et al.*, 1990, 38). However, it can be seen that efficiency is not merely a technical issue or an indication of rational behavior within utilitarianism, but is also an intrinsically moral imperative that arises from the descriptive paradigm itself.

Thus, the utility principle domesticated moral diversity for decision-making authorities by offering the capability to measure and monitor the stocks and flows of societal good, the usual proxy for good being wealth in some form. By the same process, decision-maker awareness of alternative ethical considerations was systematically attenuated. The imperative to provide for societal good at the highest level of aggregation provides no guidance for securing the happiness of minorities and individuals, even of those individuals in the happy majority.

> The guiding criterion for policy is the greatest good for society, quantitatively defined. But contemporary utilitarians, primarily economists and theorists of public choice, like Bentham, still have no principle for distributing this social good according to manifest principles of equity.
>
> (Heineman *et al.*, 1990, 40)

In contrast, the tendency of the interpretive tradition to focus on the individual rather than the nation state directs the attention of scholars working in that paradigm to the particular circumstances of decision-making rather than to the aggregate outcome. Attention to disaggregated particulars, combined with the dominance of methodological individualism, articulates smoothly with an orientation towards bottom-up, rather than top-down decision-making. The insights of the interpretive paradigm are more likely to be of interest to those who espouse libertarian or egalitarian ethics, emphasizing the rights of the individual or the minority in the face of majority preferences, as, for example, in Kantian ethics and the Jeffersonian political tradition in the US. Hence, the interpretive paradigm is often associated with a critical stance towards the *status quo*, and is often equated with and labeled as the critical tradition in social science, which marginalizes its significance by definition.

Increasing insight into the diversity of motives, values, and preferences of individuals, however, actually tends to frustrate utilitarian social accountancy, which depends on blending out such distinctions in the process of aggregation. It is hardly surprising therefore, that the insights of the interpretive paradigm are not merely considered irrelevant to, but actually have to be excluded from utilitarian decision-making in order to preserve the rationality and legitimacy of the utility principle.

Hence, the distinction between two social science paradigms is not merely an artifact for the history of ideas or a scholarly distinction of mere academic interest. It actually lies at the heart of the crisis of governance that pervades the local, national, and global communities at the start of the 21st century. That is, the tension is very real between interdependence and independence, between pursuit of the greatest happiness of the greatest number, and the assertion of individual, local, or ethnic rights that ought not to be violated even at the expense of the aggregate good. Whereas Kant's principle that every person is to be regarded as an end in him or herself is generally recognized as a form of the doctrine of human rights, Bentham dismissed the concept of rights as plain nonsense and the imprescriptible rights of man as nonsense on stilts (Russell, 1946, 742). He denounced the articles of the *Declaration des droits de l'homme* as falling into three classes: (1) Those that are unintelligible; (2) those that are false; and (3) those that are both (Russell, 1946, 742).

Similar vituperation for the social inefficiency of rights-based ethics is not unheard of among contemporary utilitarians. For example, in response to proposals by sociologist Robert Bullard that current inequities in the distribution of environmental burdens on minorities and the poor should be addressed on an environmental rights basis, rather than according to risk-based criteria, economist Albert L. Nichols responded:

> This framework has considerable popular appeal, but it ultimately is counterproductive from the perspectives of both society as a whole and even the specific groups it tries to champion. Moreover, it provides little practical guidance to environmental decision-makers trying to set priorities. ••• Bullard's proposed environmental justice framework makes continued inequities in protection more likely •••.
>
> (Nichols, 1994, 267)

Bullard replied that his proposals

> are no more regressive than the initiatives taken in the 19th century in eliminating slavery and Jim Crow measures in the US. This argument was a sound one in the 1860s when the 13th Amendment of the Constitution was passed despite the opposition of proslavery advocates, who posited that the new law would create unemployment (slaves had a zero unemployment rate), drive up wages (slaves worked for free), and inflict undue hardship on the plantation economy (loss of absolute control of privately owned human property).
>
> (Bullard, 1994, 260)

Clearly these are not merely technical arguments about the best way to clean up the environment. Similar clashes between the utilitarian- and rights-based views arise over the projected costs of climate change. In response to damage estimates that climate change will result in a decline of global productivity of less than 1% over the course of this century, utilitarians have expressed the view that only low-cost mitigation measures can be justified. On the other hand, those who espouse a rights-based approach point out that even less than 1% of global productivity over 100 years may translate into considerable suffering and premature death for millions of poor people in vulnerable regions of the less industrialized world.

The issues of risk and justice provide good loci for probing inextricable links between analytic methodologies and underlying social commitments to the Kantian individual in him or herself or the Benthamite aggregate good. Often such issues seem to be intractable when descriptive research and analysis provide the only framework for addressing them.

Typically, policy makers do approach risk characterization as a technical issue: exposure pathways, dose, response, etc. However, the technical information is unlikely to influence citizens living in an area where environmental risk is present. If the science–policy relationship remains squarely in the descriptive mindset, the response to citizen objections is likely to be collecting more technical data; the inclusion of values and worldviews will not be an option. However, if the science–policy relationship is collaborative and includes interpretive data, science will be more integrated into the policy context, more contextual and openly value laden, less oriented to mastery over natural and social processes, and more accessible to the public at large (Robinson, 1992b, 249). To the extent that scientists, policy makers, and the public can learn about each other's positions and preferences, the solution space for a problem of risk analysis becomes larger and a solution more possible.

USE OF SOCIAL SCIENCE RESEARCH

In the same way that collaboration is needed between researchers who use descriptive and interpretive approaches, researchers and policy makers need to forge more collaborative relationships. An important element of this collaboration must be the use of both approaches and multiple tools to illuminate many facets of the issues at hand. Current arrangements and policy discourses tend to favor the descriptive approach, although this was not always the case. The policy analysts of the Reformation were the hermeneutic (interpretive) religious scholars who advised both Catholic and Protestant kings and princes about all aspects of policy based on the interpretation of holy texts and secular precedents.

The descriptive approach to policy making is usually considered to be more appealing to policy makers because of its immediate potential for instrumental use. Quantitative analyses of responsiveness to tax rates or the effectiveness of regulation can, in principle, be directly translated into a set of policy choices about whether to implement a carbon tax or appliance efficiency standards, and even at what level taxes or standards should be set. In other words, descriptive research usually manages to come up with a bottom line. Generally, interpretive social science tends to be dismissed by policy makers and their social science advisors as lacking this potential to provide practical guidance. How can social scientists provide powerful, practical research findings sufficiently mindful of research limitations? Can we replace or redefine the model of scientific truth being directly used by policy makers? And what would such a research–policy relationship look like?

First, we can recognize that our model does not actually mirror reality, i.e., policy makers do not frequently make direct use of descriptive research's bottom lines. Empirical research in the US (where the instrumentalist emphasis on the bottom line is probably most strongly emphasized) shows that, despite a generally positive attitude to such analysis, it is seldom acted upon in any directly identifiable fashion (Rich, 1977; Weiss and Bucuvalas, 1980; Whiteman, 1985; House and Shull, 1988).

These studies indicate that the actual impact of descriptive policy analysis is much more diffuse. Indeed, Weiss (1982) suggests that the real usefulness of policy analysis may lie in enlightenment rather than instrumental purposes, less as a tool for solving specific problems than as a way of orientating people towards issues. And much of this is not deliberate, direct, and targeted, but a result of long-term percolation of social science concepts, theories, and findings into the climate of informed opinion (Weiss, 1982, 534).

The apparent concreteness of descriptive social science information in practice seldom makes it any more usable by decision-makers for obtaining enlightenment than the results of interpretive studies. Both may contribute equally. However, once a course of action is chosen, descriptive data may be more frequently invoked for the purposes of rationalization and persuasion (Patton, 1978; Whiteman, 1985).

Speaking (scientific) truth to (policy making) power is thus revealed as a coercive illusion worthy of Frank Baum's Wizard of Oz. The answer to what will we do if we abandon speaking truth to power? is that we will do what we have always done but with greater awareness of what we are doing . Abandoning illusions is the first step on the path to authentic empowerment of individuals and communities.

Once that step is taken, we find that paradigms do exist for the relationship of science researchers and policy makers. For example, Robinson, in a series of articles (Robinson, 1982, 1988, 1990, 1991, 1992a) has argued that the Dragnet view of science (named for the US television series whose no-nonsense detective hero would prompt witnesses to deliver Just the facts ma'am) is at the root of perhaps the most fundamental misconception underlying standard views of the science/policy relationship: that it is a one way flow of objective information from science to policy (Robinson, 1982). He proposes instead a model relationship in which researchers, policy makers, and the public form mutual learning systems (Robinson, 1992a) that use modeling tools to explore alternative futures (backcasting) rather than trying to predict the future (forecasting). Elements of this model include the explicit recognition that policy questions are not essentially questions of fact but of value, and that both a physical flows perspective and an actor-system perspective are needed to provide a usefully integrated approach to policy questions (Robinson, 1991).

Such a collaboration would also help researchers and policy makers cope with both uncertainty and ignorance about how the social and biogeophysical systems interact. Indeed, uncertainty about these interactions is of such magnitude as to be better characterized as indeterminacy. Furthermore, this indeterminacy is likely to persist well beyond the timeframe in which actions would need to be taken to prevent, mitigate, or manage potential undesirable aspects of the human nature interactions.

Making assumptions explicit is essential to make natural and social science more relevant and more effective in policy making. When applying a model or theory to a particular situation, the reflexive researcher considers carefully whether or not the assumptions embedded in the approach actually match the policy context in which the knowledge is being used. If they do not, then the information obtained will not be valid for that context; knowledge is thus conditional. Policy decisions that ignore this conditional aspect often meet with strong opposition from people who do not feel that the assumptions are valid for the case at hand. For example, in democratic societies, if political institutions base their policy decisions on assumptions about human behavior that seem irrelevant to the public's experiences of itself and the world around it, they risk eroding the very legitimacy they rely upon to implement their policies.

An important effect of a collaboration between (both kinds of) science and policy would be the inclusion of social science analyses from the industrializing world. The Southern sensibility has emerged from an experience with weak institutions of governance (Banuri, 1993). Consequently, Southern critics have challenged the modern descriptivist features of instrumentalism, impersonality, and legitimization of impersonal violence. Further, the Southern sensibility sees environmentalism as based in an integrated perception of humans and nature, placing emphasis on issues of justice, equity, institutions of governance, and property rights. Including these perspectives as data in the global environmental change debate acknowledges the

genuine interdependence of rich and poor nations and broadens the solution space for global policy making.

Re-forming the relationship between environmental science research and environmental policy making would make space for the useful research that exists within interpretive science, for the alternative world views of less industrialized peoples, and for policy making strategies that account for uncertainty and indeterminacy. The environmental science and policy community would then include needs, wants, and beliefs in its data sets alongside measurements and statistics. Policy decisions and agreements would explicitly include social organization data and cultural assumptions as well as market and consumption data in global environmental policy decisions to make them more implementable and effective.

The Emergence of Global Environment Change into Politics

JOHN DUNN

University of Cambridge, Cambridge, UK

Unlike most major elements of contemporary politics, global environmental change entered the political eld, not under the peremptory impress of immediate political incentives, but through a slow, vague, diffuse and uneven shift in belief. The beliefs in question, moreover, were not about the properties or potential conduct of fellow human beings, but about the residually non-human setting of human life in its entirety. Local environmental change, apparent or real, has been seen as politically signi cant throughout the history of our species, in myth since Noah's ood, and in recorded reality since at least ancient Egypt. Even today most environmental changes which are seen as politically important are relatively local in incidence or highly differentiated in their spatial signi cance (Elliott, 1998; Held et al.*, 1999). Global warming has very different medium-term implications for the inhabitants of the Maldives or the Sahel than it does for those of Berkshire. The holes in the ozone layer, when they appear, cover some bits of the humanly inhabited map and not others. To see global environmental change as a factor and focus within contemporary politics is not to ignore (still less to deny) this drastic variation in impact and signi cance. It is simply to register the cumulative effect, and the awesome prospective signi cance, of a novel practical preoccupation and a fresh way of seeing the setting and destiny of human political life as a whole. It is easier, naturally, to plot the cumulative effect thus far than to assess the prospective signi cance (Dunn, 1998). But since the impact so far in practice is relatively modest, and the prospective signi cance at the limit genuinely eschatological (the termination of human life through the consequences of human action), it would be an error of judgement to concentrate principally on the more tractable topic.*

Since global environmental change emerged into politics in the first place through a hesitant change in belief and not an abrupt alteration in the matrix of political incentives in any definite political location, it can only be understood adequately by identifying where that shift came from. At present we do not really know. We still have no compelling and thorough intellectual history of the interactive dynamics of the large range of natural sciences whose combined cognitive resources give us our best assessment, either of how much damage the natural setting of human existence has already undergone, or of how rapidly we can expect it to continue to deteriorate, or even of what could, in principle, be done effectively to retard, halt or reverse some of these processes of deterioration. We have no coherent synthetic study of the often very idiosyncratic and obsessive personal odysseys of individual scientists or publicists who picked out major sources of continuing damage to habitat, and conveyed them eloquently to mass audiences in countries which permitted such communication. Either of these would be an exacting technical exercise in the contextual history of ideas (Dunn, 1996). Each, if it was done convincingly, would carry important implications. Because the major capitalist countries today still make the primary contribution to global environmental deterioration through the continuing momentum of their productive systems, and since they also, at present, continue to provide much the best access to public media and the least obstructed channels for mass communication, some of the main political ambiguities of their emerging preoccupation are already writ large in both of these two histories. As yet, however, none of us can do much more than guess intelligently at the contours of the histories themselves. It is extraordinarily difficult in principle to explain why any important passage of intellectual history should have gone as it did, not least because these passages necessarily contain episodes of real intellectual creativity (Quinton, 1999). Intellectual creativity, for reasons made familiar by Karl Popper's supposed proof of the impossibility of predicting the future of any natural science (Popper, 1957), may just in detail be beyond human explanation.

What certainly is important in this sporadic and amorphous shift in belief, however, is its timing, its

location, and its dependence on rapid diffusion of images and judgements, on the relative independence of such diffusion from the immediate purposes of holders of political authority, and perhaps, too, on a certain dedicated obstinacy and crankiness on the part of some of its main carriers. For major shifts in belief to be practicable at all, it is necessary for their protagonists to be able to endure loneliness and unpopularity, and to be willing to seem and go on seeming damagingly eccentric.

Many very different things happen as global environmental change emerges into politics, but one disconcerting and inevitably elusive thing which does so is that quite bizarre and apparently personal obsessions of the far periphery move insistently towards the centers of power, responsibility, judgement and eventual choice in world politics. This is not a process which anyone's personal or professional experience of politics can equip him or her to chronicle with much ease or assurance. It is a standing temptation to confident misjudgements from virtually any angle. But it is every bit as important for the human future to learn to see it more accurately as it is to learn to judge more accurately just how deeply and in what ways we are still damaging our habitat, and what we can do to improve our judgement adroitly and at some speed. If we are to do so, we must improve our collective assessment of whom or what to trust (or distrust) to instruct us on the risks which we are running, on how these risks can be minimized, and against which of them we can, to any significant degree, insure ourselves by other courses of conduct which remain open to us. All of these are political tasks as much as cognitive puzzles. None of them is a matter about which any individual human or group of humans can yet be said to know exactly what is the case (let alone what could become the case). Some of them are matters about which the very idea of exact knowledge is probably confused in the first place.

When social scientists or politicians now speak of the emergence of global environmental change into politics, what they have in mind is not merely this morass of political suspicion and bemusement. It is also the appearance, in a readily specifiable set of institutional sites, of a relatively determinate agenda of novel concerns (Hurrell and Kingsbury, 1992). The concerns themselves may have come originally from quite personal and historically contingent acts of judgement on the part of particular individuals, but they have become an agenda through an increasingly definite and insistent political process. They have imposed themselves first on the attention, and then on the purposes, of those in authority (insofar as they have any) by at least threatening to limit or were remove the power of those who were previously unaware of them or were more than prepared to ignore them. By this stage, plainly, they had indeed altered the matrix of political threats and rewards faced by professional politicians in and out of office, and made their inroads precisely by doing so. In this process personal change of belief broadens out into the modulation of public opinion, and public opinion, in turn, in due course condenses into an effective political force pressing political leaders in novel directions.

To map this diffusion accurately it would be necessary to relate together very variegated sorts of changes, from the creation and development of political parties, non-governmental organizations (NGOs) or pressure groups, through the impact of each of these on the dynamics of party competition in different nation states, and on to the impact of all of them together on state bureaucracies, inter-state negotiations, treaties and their enforcement, and the creation or modification of international organizations, initiated by state decision but exerting, for some purposes, at least a persuasive or normative authority over the states which have created them. As global environmental change emerges into politics, it does not merely create a new agenda and a novel political field centered on that agenda. It also forges a multiplicity of fresh institutions and practices which take that agenda for their own and press different elements of it to what they take to be their own (and the globe's) advantage: this provides both a milieu of existence and an endless series of actual or potential teams of action, usually competing more or less acrimoniously for attention, financial resources, influence, and even power.

While the agenda and many of the participants are novel enough, many of the constituents of this new field are altogether more familiar. They were there before; and they depend neither for their power nor for their *raison d'être* on this novel field. This is uncontroversial in the case of nation states and much of their public bureaucracies. It is uncontroversial for the main legal and organizational frameworks of the national economies, from whose interactive global dynamics the environmental changes largely emanate. It is even uncontroversial in the case of the principal international sites of political or legal authority – above all the United Nations (UN) itself.

The new institutional sites are at most subordinate agencies of older institutional sites which still clearly hold greater authority, or (in the case of Green parties in a number of countries as yet principally in Western Europe) competitors of limited efficacy with older and better entrenched institutions in the same settings. Only in the field of pressure groups or NGOs (Greenpeace, Friends of the Earth) has the novelty of the agenda yet bred correspondingly novel types of agent with the vitality and innovative capacity to press it home in essentially unprecedented ways.

All of these sites offer an opportunity for careers open to talent, energy and luck, and redirect political initiatives accordingly. There is no *a priori* reason why some of them should be more important, more dependably benign, or more irredeemably corrupt than others. Some analysts or participants put such trust as they can muster in NGOs

or in the conceptually still more diffuse substance of civil society, global or national. Others not merely focus on, but presume the essential practical rationality of, at least some existing states or institutional processes of inter-state cooperation. Others still place altogether greater confidence in the heuristic delicacy and epistemic reliability of market processes, confining their political attention to the question of how to minimize impediments to the latter's functioning by designing an optimal regulatory regime.

None of these viewpoints is simply inane. But none offers a privileged perspective on the bewilderingly complex and still largely opaque field which the agenda of global environmental change is attempting to address. This is not as yet a field which can be surveyed as a whole with any assurance from any given human vantage point. There is no strong reason to believe that it will ever become such. To improve our understanding of it, we must divide it up into more manageable components, and postpone asking how these components in the end bear upon one another until we have mustered a reasonably complete and accurate inventory of each of them.

It is best to begin with the immediate sources of the most drastic global environmental changes, which plainly fall in the realm of economics. Some important, and often environmentally highly destructive, forms of economic production are closely tied to the logic of military competition today (Held *et al.*, 1999), as they have been for several centuries in the past (McNeill, 1983; Kennedy, 1988). But the principal dynamic source of environmental degradation is still a process of acutely competitive expansion in the production and exchange of goods and the diffusion of services, driven on the supply side by the quest to accumulate capital and on the demand side by the quest for greater and more rewarding consumption. There is little agreement, unsurprisingly, on whether the global economy forms in any real sense a unity, or whether it is governed by a single overarching logic (Brenner, 1998; Wallerstein, 1995; Little, 1982; Lal and Myint, 1994). There is still less agreement as to whether the process of economic development itself implies a predestined direction for the future evolution of economies and polities across the world, or even on where that direction is most likely to lie. Is the world trading system likely to be more liberal or less so in 25 years time? Are there likely to be many more, or far fewer, or roughly the same number of clearly consequential sites for major political or economic choice in the world in several decades time? But while there is sharp dispute over the degree, scope and significance of present globalization, and the inevitability or otherwise of future globalization, and some variation in optimism about the possibility of generating more sustainable patterns of development within the next generation or two, virtually no coherent analysis of the politics of global environmental change assumes marked and protracted retardation of growth in the production and consumption of goods and services, the velocity of economic transactions, or the flow of international trade. This may be more an index of cowardice or failure of imagination than of rationally secured belief. But the continuity of assumption across sharply contrasted personal dispositions and political tastes is an important political factor in itself, and has done much to shape the sequence of international diplomatic negotiations on response to global environmental change which have centered on the new agenda and provided its most prominent and potentially consequential entree into politics.

To focus in this way on global economic dynamics is not to presume that all political action is prompted in the last instance by a narrowly economic causality. But it certainly is to accept the decisive role of economic struggle and effort in setting the limits to political possibility in this domain, as it does throughout modern politics (Dunn, 1990b). Politics sets its own limits, in return, on how economic activity can be and is organized (Dunn, 1999). But in a human world so comprehensively reshaped by the history of capitalism, it does so throughout on terms which are obtrusively set by the requirements for competitive success on markets which, however doctored they may be, can never be fully controlled by political choice. One very important practical question which is already being tested in the domain of global environmental change is whether (and how far) collective political intelligence and can hope to re-establish control over the blind, convulsive, irresponsible dynamics of competitive economic effort. This has been under spirited dispute for several hundred years; and the answer remains disconcertingly open, not least because a less discerning review of political will, examined over time, makes it all too clear how much easier it is to disrupt or obstruct large-scale economic activity than to bring it under firm control. This is as much a truth about economic organizations themselves as it is about the interaction of formally political with formally economic institutions. But its political significance is every bit as momentous as its significance within narrowly economic activities.

What made it politically impossible to ignore global environmental change any longer was the transformation brought about by the great economic boom after the Second World War which came to an end in 1973 (Brenner, 1998). The next quarter of a century may have seen less rapid growth in the more advanced capitalist economies, and some degree of regression for extended periods of time in state socialist economies and their uncomfortable successors (Brenner, 1998). But, virtually throughout, it also saw a continuation of net global economic growth, and growth from an initial level so high that the pace and scale of global environmental degradation became at least blearily apparent to the most myopic and irresponsible holders of state authority. (See Held *et al.*, 1999, 390–396 for an account of the progress of global environmental degradation and its economic embedding.) As it did

so, it set up and intensified a steadily more obtrusive and extensive network of diplomatic interactions, institutional invention, and attempts to modify economic and political practices to diminish the harm which they were so conspicuously inflicting. At stake throughout this political and economic adjustment were both the urgency and relative priority of minimizing particular threats, the range of expedients through which the diminution might most effectively be undertaken, and the necessarily vexed question of who precisely was to pay for it and at whose expense. The relative urgency of minimizing particular threats was initially the preoccupation, principally of political amateurs, with a high degree of sensitivity to environmental vulnerability. But even it penetrated the world of professional high politics with some rapidity from the early 1980s, reaching as unlikely targets as Britain's Prime Minister Margaret Thatcher. The assessment of how best to meet these threats clearly required diplomatic and economic expertise but she soon convinced career politicians and public officials of the importance of addressing it. The allocation of responsibility for meeting the bill, still more clearly, was the stuff of high politics and intense interstate diplomatic activity throughout.

The core of this process of recognition and incipient political response was a series of major international conferences, running from the UN Conference on the Human Environment in Stockholm in 1972, to the UN Conference on Environment and Development in Rio in 1992 (Elliott, 1998, Chapter 1). Before 1972, international agreements which bore directly and explicitly on the protection of the environment, focused principally on the preservation of wildlife, the law of the sea (alongside the law of war, the first major focus of efforts to develop a truly international law), and from the 1970s onward the attempt to contain the obvious and acute threat of nuclear armaments, like the menace of nuclear winter (Elliott, 1998, 8–11).

The danger posed by nuclear weapons, for obvious reasons, was a focus of very high and distinctly arcane politics from the point at which the scale of their potential for destruction first became clear to anyone but nuclear physicists – in effect from the Manhattan Project onwards. An intensely controversial issue throughout this history has been just what did in fact determine the political and military choices made by state powers, not merely over the deployment or use of nuclear or thermonuclear weapons, but even over the development of civil nuclear power as a basis for national electricity supply (Alperovitz, 1995; Clark and Wheeler, 1989; Freedman, 1981; Gowing and Arnold, 1974; MccGwire, 1987). Because it has been so intensely politicized and so evidently consequential throughout its history, both within particular states and still more so in the more conflictual relations between them, this has been the last area of global environmental degradation in which public opinion has made a clear political impact. Even in countries like Sweden, where popular attitudes have been deeply affected by Green awareness for decades, the politics of transforming a domestic electricity industry, largely based on nuclear power, have been as slow as they have proved painful. Not even the disastrous explosion in the Chernobyl nuclear reactor in 1986, the pollution which this scattered so rapidly over such immense distances, and the dramatic impact of this on European, and indeed, world public opinion, proved sufficient to accelerate the shift from nuclear to other energy sources for electricity production. What it may well have done in retrospect, however, is to halt the formidable momentum of the nuclear industry up to that point.

The concern for the preservation of wildlife had a protracted imaginative past in the slow modulation of European conceptions of the proper relations between human beings and other living creatures (Thomas, 1983; Dunn, 1969; Passmore, 1974). But it had, of course, a very different imaginative past in other areas of the world, whose religious traditions had long taken a less anthropocentric view of the relative significance of humans and other creatures (Gombrich, 1971; Carrithers *et al.*, 1985). In European colonial or imperial territories, and above all in British India, the practices of preservation were often more closely linked to the preservation or extension of elements in the lifestyle of a land-owning aristocracy or gentry than they were linked to the systematic commercial exploitation of natural resources, or the attempt to contain the damage which this was always likely to inflict.

In the peculiarly ecologically vulnerable continent of Africa, interstate agreements between the European powers to preserve wildlife were signed as early as 1900, virtually as soon as the scramble for Africa was completed, and well in advance of the more far-reaching Convention on Nature Protection and Wildlife Preservation of 1940 which covered the western hemisphere as a whole. In the African case, it seems clear, the 1900 agreement was not a response to extensive damage already plainly done, but rather a conscious prophylactic exercise in stewardship, reflecting a deliberate acknowledgement and assumption of human responsibility for non-human nature (cf. Passmore, 1974). This may have had very limited effect on the dynamics of subsequent ecological degradation. But it certainly confirms that concern for such degradation is neither a recent prerogative nor necessarily an index of deep political disaffection in the face of existing political or economic power or privilege.

A purer case of eventual cultural revulsion at the environmental destructiveness and brutality of the exploitation of land resources over a far longer period – in fact several centuries – is given by the territorial subjugation and ethnic displacement which marked Europe's impact on the North American continent (Cronon, 1983, 1992). In the United States, popular organizations for the preservation

of wilderness areas and bird and animal species (the Sierra Club, the National Audubon Society) helped both to prompt and also to respond the opportunities provided by the National Parks network (Runte, 1997), and furnished a potent basis of organization and experience for the very much larger numbers of private citizens who began to sense the ecological crisis which faced their country in the 1960s and 1970s.

One way of seeing what has happened in the emergence into politics of global environmental change is to see this as the rapid and disconcerting confluence of two startlingly different sorts of political setting and two starkly contrasted types of human meaning. One setting is the exercise of statecraft from the summits of highly organized and always prospectively coercive pyramids of power and authority. The interpretation of the goals of statecraft and the constraints upon it is always open to fierce dispute; but over time it strongly favors a focus on the distinctive rationality and the often singularly perturbing *mores* of states as such: on *raison d'êtat* (Meinecke, 1957). The other setting is the movement of the individual soul or sensibility, increasingly importuned within the cultural history of the West, to respond with Romantic excitement and veneration to the wonder of the rest of nature, the non-human setting of human life, and to measure itself by the depth and energy of its response (Taylor, 1989, 1992; Unger, 1999).

A third setting and type of meaning, the economic rationalization of production and exchange under an increasingly globally pervasive capitalism, has penetrated both ruling elites and popular sensibilities quite deeply, but in very different ways. It has moved the imperative of economic efficiency ever closer to the center of *raison d'êtat* (Dunn, 1990b; Baldwin, 1992; Keohane, 1984; Gilpin, 1987). But it has also inflamed the post-Romantic sense of spiritual self-regard in the face of the dizzy commodity fetishism of modern mass consumption, and has intensified revulsion at the cumulative damage which this inflicts. In the earlier stages of these twin developments, it was easy to doubt that their simultaneous occurrence could be of any enduring political importance. How could the personal, the aesthetic, and the often self-consciously unworldly, converge effectively with the carefully self-protected and heavily armed sites of ultimate coercive authority and organizational control in collective human life (in their own vision, largely impersonal, deeply inured to ugliness, at least at a safe distance, and worldly to the last degree)? This was an encounter for which neither element could genuinely and clear-headedly wish, especially in its earlier stages: at best a collision which was bound to deform many of the purposes which came together in it, at worst a nightmare chaos which threatened all that each held dearest. For state elites, even in a representative democracy, this perspective cannot readily change. For them, the shifting preoccupations of their fellow citizens are always more likely to prove an irritation or inconvenience than a steady source of gratification. But the citizens, consumers and producers, who give these elites their power as well as their legitimacy, have their own lives to live and naturally prefer their own wills and sentiments to bear on the ways in which they are governed. In representative democracies, moreover, they are assured that this is both a right and a genuinely available opportunity (Dunn, 1992).

The increasingly hazardous and alarming momentum of global environmental change was thus a brusque threat to the format of existing politics and to the imaginative habits and practical routines fostered and reinforced by that format. Above all, it was a challenge to the implicit assumption that these were in good working order and could be confidently trusted to take effective care of the ongoing destinies of modern human populations on the latters' behalf, and without too close invigilation from outside the ranks of their habitues. It was also thus a challenge to the existing institutional division of political, social and economic labor, and to the professionalization of political and public bureaucratic life. What it suggested, above all, was not that the existing incumbents of high political and bureaucratic roles should be cashiered and promptly replaced with human alternatives with different tastes, dispositions or purposes, in the manner suggested by the development of the routine organizational apparatus of modern representative and administrative politics since the French Revolution (Finer, 1997; Manin, 1997; Dunn, 1992, 2000). Instead, it was that these roles, as a whole, should somehow be deinsulated, and opened up to far more diffuse, and often instrumentally pretty unreasonable, movements of taste and surges of anxiety, dispersed across the population at large. This was a prospect calculated to dismay any self-respecting political class or professional stratum; and it was obvious enough that it could readily and rapidly do far more harm than good (as it may already have done in a number of prominent instances, like the Brent Spar oil platform disposal decision). What was not obvious was how it could well be avoided, or what more promising model of overall political and institutional transformation was in principle available.

As it emerged into politics, the hazards of global environmental change underlined, above all, a need for rapid large-scale transformation of many prominent human practices. A case can be made for seeing the key site for this change in three distinct ways – as lying in the realm of culture (in the conceptions of the goals of human life and the consequent living priorities of given human populations); as lying in the main organizing logic of economic activity; or as lying in the genesis and strengthening of new institutions of coordination and control, which can determine how every human population will in fact respond to the newly recognized, and ever less comfortably parochial, context of its physical existence. These different locations of the

need for change clearly imply very different strategies for fomenting change. Judging their current plasticity or potential responsiveness is not merely largely the prerogative of different academic disciplines. It also requires, at least in the first instance, a hypothetical presumption of relative stability in each of the other two.

A world of generalized and indeterminate flux cannot be assessed coherently from any particular angle, and precludes firm judgement, even in principle, on how best to respond to it. Such a world is no more tractable in practice; but at least it does not rule out comprehension in principle. Seen over time, moreover, it is distinctly less discouraging even in practice. Thirty years ago, very little of our present scientific basis for assessing the more salient elements in global environmental change was yet available. Much of what we can now determine with relative accuracy was a matter for the purest (and most projective) speculation. Today many of the most consequential judgements of the degree and imminence of the peril in which we stand remain alarmingly unclear, and hence continue to be fiercely contested even by the ablest scientists directly concerned. Some of the most devastating potential scenarios are likely to remain effectively imponderable in any foreseeable future. But we have no reason whatever for seeing our world (as a whole) as a domain of generalized and indeterminate flux, and every reason to hope that we may succeed in determining what, within it, is modifying what, and in what ways, far more accurately and sensitively, even in the next few decades. To do this, we need above all to learn to take the formats of our existing fields of academic or cognitive specialization more lightly and less literally – to see these formats more as precarious and politically driven artefacts, and less as cultural treasures or dependable deliverances of the obvious. When and if we learn to do this, the hypothetical bracketing of adjacent cognitive domains will become both easier and more natural, and we can begin to learn how to judge how each given domain bears on the others. In place of a categorical assumption of external fixity grounded mainly in intellectual habit, or an epistemically gratuitous presumption of infinite social and political plasticity grounded solely in personal temperament, we can hope to develop a controlled heuristic strategy of open inquiry. Such a strategy could (and would need to) interrogate all elements of the motivation, interactive dynamics and institutional context of human behavior, in face of a still rapidly deteriorating habitat, and address throughout the question of how that deterioration can be arrested or reversed.

If we think of these three potentially decisive sites for adjustment, and see the adjustment itself as a single collective task for our species over time, it is clear at once how hard it is to judge how much of the task can sanely be assigned to each site. If the crucial site proves to be the domain of culture, the task is one for the human spirit: this is because the fundamental, but endless choice of all human beings is what sort of persons we wish to be and what sort of lives we wish to live. Assessing grounds for hope (or despair) in this domain is an ancient human preoccupation: a task in the first place for religious practitioners or moralists, and then perhaps, more academically, for theologians and philosophers, historians, sociologists or psychologists, especially, in the end, perhaps for psychologists. The inductive record here is certainly discouraging. Grounds for despair come at least as readily as grounds for hope. And hope itself, when it does come, seems often to come less from grounds of any specifiable kind than from sheer biological vitality. Can psychologists learn to judge the fundamental properties of the human spirit? Can they in principle ever tell us, even over a very long span, whether or not a human being is a kind of creature which could learn, morally, to live far more responsibly, temperately and delicately than ever before in any numbers? Can a person learn a very different level of patience, tolerance and generosity towards immense numbers of fellow humans quite far away, of whom very little is known? Modern capitalist civilization is founded on the focusing and intensification of the effort to get what we want and to live, within its ever shifting contours, as happens to please us: on the pursuit of modern liberty (Constant, 1988, 313–328). Can this, in principle, be transposed into a tissue of tasteful and dependable self-inhibition in the service of a threatened global ecology? On balance the historical odds seem clearly against it. Perhaps no psychologist (perhaps not even psychologists as a profession in their entirety) can be said to know this to be a task beyond the unmediated resources of the human psyche. But insofar as it is cumulative at all, the intellectual history of psychology as a would-be science leads us to expect it to prove so. And however limited their present contribution to telling us whether we collectively possess the spiritual resources to preserve our global habitat, it is at least less paltry than the advice which they can yet offer on the question of how best to mobilize the resources which we do have for the purpose.

If the crucial site is the organizing logic of economic activity, the task is principally for economists, for those who design and implement governmental economic policy, and above all for those who lead and manage very large economic enterprises. The key problem here is how to modify structures of incentives so that at least as much continues to be produced and exchanged indefinitely, but with altogether less attendant damage. The task is to alter the grounds for action of economic agents, to limit negative externalities, and to do so without impairing the dynamism, or flexibility of adjustment, of the overall economic activity off which, through which, and within which, human populations all now live. There has been very extensive study of the economics of global environmental problems over the last three decades, and some definite intellectual

headway in analyzing both their sources and the range of means through which it might be possible to handle them effectively (Dasgupta and Maler, 1997; Mabey *et al.*, 1997; Swanson, 1996; Haugland *et al.*, 1998).

What is already clear from this study is that, whilst there are no rigid economic obstacles to lessening the pace and scale of environmental damage, the costs of halting or reversing such damage, even where it could in principle be reversed, are vast enough to preclude its reversal in many fields in the imaginable future. Equally clearly, the allocation of these costs between different groups of human beings over time is a matter of politics through and through, and certain to remain just as bitterly contentious for the imaginable future as it has already proved over the last quarter of a century.

If the crucial site of decision is neither in culture nor in the technical design of economies, but in the devising and implementation of novel institutions of coordination and control through which to recapture some degree of control over our cumulative damage to our habitat, the challenge in the end is to our capacities for reflexive prudence and political cooperation (Dunn, 1990a, conclusion). The task is, above all, one of political understanding and political action.

A pessimistic view would see all three of these tasks as already unmistakably beyond us. The spiritual assignment of chastening greed, enhancing temperance and composure, and guiding us back into a more serene harmony with the rest of the world which we have so deformed and defiled, suggests familiar Platonic remedies for spiritual corruption: a harsh censorship, a formidable closure of experience, a rigid structure of authority, made politically credible only by uninhibited cultivation of dubiously noble lies. This defies the logic of modern politics and modern economics more or less in their entirety. There is no reason whatever to believe that the power could still be mustered to impose it, and every reason to fear that the harm which it would certainly do would massively outweigh any possible good that might also flow from it.

The economic assignment of internalizing the negative externalities suggests an endless battery of technocratic expedients, of which the only aspects about which we can yet be reasonably confident is that most of them will not work in practice, and that, in their entirety, they will largely reproduce the drastic inequalities in life chances everywhere embodied in existing economies, and reinforce the acute resentment which these already arouse. The political assignment of judging together what our predicament really is, choosing together how to respond to it, and cooperating with one another to ensure that these choices are implemented, suggests familiar oscillations between the invention and parading of international institutions for cooperation, and sustained haggling and mutual intimidation within these (along with other older sites) to impose the costs even for the outcomes which we do, on balance, favor on others who are even worse placed to afford them: an unrelenting struggle in which the strongest members of society will still take what they can and the weak still yield what they must (Thucydides, 1921, 158).

Neither the spiritual, the economic nor the political task, however, can safely be written off. In all three, some degree of contribution is almost certain to prove indispensable, if any secure headway is to be made in such a devastatingly complicated, slow, unobvious and sequentially uninviting endeavor. The least rewarding to focused thought in the short run is the direct assault on the psyche, not least because the focus in question is so extraordinarily hard to maintain. Much more promising is a careful reconsideration of the relative elasticity of technocratic economic expedients and more overtly open-textured political conceptions and practices. The economic expedients (above all the design of regulatory regimes and tax systems) can articulate with some precision with the still more plainly technical appraisal of the dimensions and rectifiability of environmental degradation, to make up a joint agenda of what most imperatively needs to be modified, and how it can best be modified. This would certainly not show that we can so modify it in practice. But it would make it as clear as it can be made that we must possess some good reasons for wishing to modify it. The agenda of global environmental change over the last quarter of a century has been an attempt to capture such a joint assignment (Brenton, 1994; Vogler and Imber, 1996; Tolba and Rummel-Bulska, 1999; McCormick, 1995). The diffuse but sometimes very vigorous political processes which came to bear on the major international environmental meetings from the Stockholm summit of 1972 to the Rio Summit of 1992 and since (Thomas, 1994), and which now permanently surround all governmental and intergovernmental environmental policy-making, have been a sustained attempt to interpret and implement that agenda in practice as their participants judged best.

The UN Conference on the Human Environment, held in Stockholm in June 1972 (Elliott, 1998, 12) in the presence of the Prime Ministers of Sweden and India, set the pattern for subsequent diplomatic and organizational initiatives in limiting environmental damage by issuing a declaration, adopting an Action Plan, and spawning the new UN Environment Programme (UNEP), founded in 1973, with its headquarters in Nairobi, under the leadership first of the Canadian Maurice Strong and then of the Egyptian Mostafa Tolba (Tolba and Rummel-Bulska, 1999). From its foundation, this organization represented a precarious (and very poorly funded) compromise between the competing anxieties of the wealthier and poorer countries, and a clear concession to the fears and jealousies of existing UN agencies. But its subsequent impact on a string of influential meetings to assess and respond to global environmental

change in many different fields (Elliott, 1998, 109) was not merely a testimony to the skills and determination of its own leadership, but also an index of the increasingly evident urgency of the issues at stake, and the diplomatic and political advantages of approaching these, not through the political apparatuses of individual sovereign states, or the cumbersome machinery of the UN General Assembly, but through a specialized institution fully devoted to the purpose. In the two decades between the Stockholm meeting and the much larger and more ambitious UN Conference on Environment and Development held at Rio de Janeiro in June 1992, the agenda of global environmental deterioration became much more dense and more differentiated and acquired a quite new political momentum. It also generated a wide range of new institutions, practices and agreements to monitor or respond to the many different dimensions of environmental degradation. By the time of the Rio meeting, the national delegations accredited to the conference were larger and more numerous, and in many cases led by their respective Presidents or Prime Ministers. In addition they were officially supplemented by over 1400 accredited NGOs; and the conference itself was paralleled by a Global Forum with more than 30 000 participants, held under NGO auspices and organization (Elliott, 1998, 19). Both the conference itself, and the activities surrounding it, were the focus of unprecedented media attention. By its close, the conference had adopted three wide-ranging formal agreements and drawn up two major new conventions, one on climate change and the other on biodiversity.

Even in retrospect it is hard to distinguish the ultimate effect of this flurry of diplomatic activity from the rhetorical vigor and invention lavished upon it, and the individual and institutional careers advanced by it. A skeptical assessment would see the main clear gains as lying in the strengthening and extension of the global apparatus of scientific monitoring, and the political affirmation of the urgency and priority of the goal of limiting further ecological degradation, rather than in the relatively modest and still largely unimplemented provisions for forest protection embodied in the Rio Statement of Forest Principles (Elliott, 1998, 85–89), the precariously coherent Framework Convention on Climate Change, the practical impact of which remains very much in contention (Elliott, 1998, 68–73), or the Convention on Biological Diversity, which has little immediate prospect of slowing the rate of species loss in marine or forest environments (Elliott, 1998, 73–89). In all of these domains, what does decide the ultimate outcome of such initiatives is not the personal political taste of a small range of powerful political leaders in wealthy countries (let alone of a much larger range of leaders of much poorer ones). It is the balance of political and economic force in intensely fought distributive struggles across the economies and societies of the world. It is never, in principle, possible to see what that balance is at any point in time, although it sometimes becomes quite easy to judge in retrospect what it must have been, with several decades of hindsight.

In interpreting the pace and vigor of political response to perceptions of environmental deterioration, it is most illuminating to consider separately the relative technical tractability of the project of arresting or reversing the damage, and the structures of interest involved both in suffering the damage itself and in bearing the cost of averting it. Where great concentrations of wealth or economic power have a large stake in things as they are (the eating habits of Japanese consumers at the height of the bubble economy, the energy industries of western powers, or indeed of the former Union of Soviet Socialist RepublicsUnion Of Soviet Socialist Republics (USSR) and its successor states), the political assignment of altering them rapidly is virtually impossible. Where the great majority of the world's present population have a large (and in the short term an inextricable) stake in things as they are, it is also normatively uninviting. Assigning the costs for arresting global warming with any rapidity is not merely a matter of balancing the power of very powerful interests against the human needs of very large and poor populations; it is also a matter of balancing huge short-term costs against potentially even vaster long-term gains, in a political context in which the losses are devastating and impossible to overlook, while the gains cannot in principle be guaranteed to accrue at all, and will accrue, if they eventually do, only to persons who are in many cases quite different from those who now bear the costs (Parfit, 1984). Ecological degradation harms the interests, and arguably violates the rights and threatens the needs, of future generations of human beings. But any allocation of the costs of seeking to forestall it is bound to entrench on the interests of some present or future human beings, and quite likely in practice to impair the rights, or even encroach on the needs, of many groups of human beings who have no idea of what is at stake and no means of defending themselves against the measures in question. The politics of global environmental change cannot therefore be validly understood as a struggle between virtuous, clairvoyant and deft NGOs, consciously devoted to world salvation, and vicious, obtuse and clumsy states or corporations, more or less inadvertently committed to world destruction. Nor, self-evidently, can it be validly understood as the mirror image of such a struggle, with the normative signs reversed. What it is above all is a very maladroit and confused exploration of just how dangerous and destructive global environmental change really is, and an understandably acrimonious range of quarrels about who is to blame for its grimmest aspects, and who has either the responsibility or the power to begin to cope with them. Anyone who finds this surprising would simply show that they do not understand what politics is really like or why it is as it is (Dunn, 2000).

The speed and clarity with which environmental damage is identified and challenged in the first place has depended, throughout human history, both on the freedom, confidence and political effectiveness of its immediate victims, and on the salience of the damage itself. The pace at which that damage is arrested and reversed depends at least as much on the technical tractability of the process to intentional human intervention. When the Iraqi occupying forces set fire to the oil wells of Kuwait, their political master fully intended the scale of destruction which he unleashed. But most important environmental damage is an unintended side effect of activities pursued for quite other reasons; and a very large proportion of it is still as unwelcome as it is unanticipated.

If we consider six of the major dimensions of global ecological degradation in relation to one another – cross-border acid rain, stratospheric ozone-depletion, deforestation, loss of biological diversity, and global warming (with its attendant threat of massive climate change), it should by now be possible to explain much of the pattern of political response by relating together their relative salience, the political strength or weakness of their immediate victims, the power of those with a major stake in the activities which principally cause them, and the costs and technical tractability of beginning to remedy them. Unsurprisingly, no one has yet attempted an overall interpretation of this ambition. (For a thoughtful and well-informed synoptic view see Held *et al.*, 1999). But it is not difficult to suggest its main outlines.

Marine pollution has been one of the earliest foci of interstate environmental concern, both because of the obtrusiveness of some of its aspects, and because it is so plainly, in most cases, beyond the authority or power of any particular state to control or rectify. In the case of more vulnerable seas in areas with relatively wealthy populations (the Mediterranean, for example), the dangers were identified relatively early, and attempts made to remedy them. But the main threat of marine pollution has come from the vast expansion in world water-borne trade since 1945 and the hectic development of the world oil industry, especially from off-shore fields in the last quarter of a century. The starkest destruction thus far has come in the case of huge inland water bodies in the former Soviet Union (Lake Baikal, the Aral Sea), where the immediate victims were effectively politically impotent, and from major oil spills. Particularly vulnerable major sites at present include the Arctic and Antarctic regions (where the international attempt at environmental protection has been especially strong, not least because initial territorial appropriation was still minimal), and the Caspian Sea, which is both a fully enclosed water body and the site of vast oil and gas reserves in a populous and still relatively impoverished region.

Marine pollution remains extraordinarily difficult to police, with the relation between those who inflict and incur its costs in most instances impossible as yet to turn into structures of clear mutual accountability. But it is reasonable to expect much further effort to make them more so, because the interests in marine pollution cannot in principle, over time and under accurate interpretation, outweigh the interests in preventing it. Since the interests in its continuance for the most part also lack tight and firm links to major state powers, and the technical possibilities for enhanced surveillance must be virtually limitless, in the end this effort is likely to win some success. Only in the case of the oil industry is it hard to imagine rapid progress in arresting marine damage; and here the explanation is less the sinister political linkages of major oil producers than the virtually worldwide mass interest in continued access to low cost energy supplies, especially for transport, cooking, and over much of the world, heating. It is not an accident that the most prominent and entrepreneurially dynamic executive of a major oil company over the last few years, Sir John Browne of BPAmoco, should also be the most prominent exponent of the imperative for the industry to respond effectively to the cumulative threat of its environmental damage.

In Western Europe cross-border acid rain was the first major political focus for environmental concern and resentment in the post-war epoch, with the forests and lakes of Scandinavia as the most evocative site of harm, and the principal perpetrators seen as the cars, trucks and power stations of the UK and Germany (Held *et al.*, 1999, 404–405). Due to the relative diplomatic and economic intimacy of Western Europe, some degree of accountability for these harms was established with comparative ease, and sustained effort has been made for at least a decade to modify the technologies of power stations and road transport to cut levels of nitrogen and sulfur dioxide emissions. A more recent and alarming example of cross-border atmospheric pollution was the month-long smog which engulfed much of the Malay peninsula and Northern Indonesia in the summer of 1997 as a result of Indonesian forest fires. Here, the prospect of rapid adjustment to avert further damage seems poor, since the level of cooperation and mutual confidence embodied in the South–East Asian Nations (ASEAN) is still distinctly lower than in the case of the European Union, the immediate economic circumstances of the majority of the populations in question already straitened, the dynamics of economic growth severely disrupted, and the political coherence and efficacy of the Indonesian state still far below those of any Organization for Economic Cooperation and Development member. An even less promising site for prompt rectificatory action is the atmospheric pollution induced by traffic, power stations, and in many instances wood-burning, in the vast metropolitan urban agglomerations of the world's poorer countries, from Delhi to Mexico City.

Paradoxically, the most encouraging instance of political response to global environmental damage has come

from one of the more recently identified and unnerving examples – the damage to the ozone layer, with its sharp prospective increase in harmful radiation. The source of that damage has been the use over the last half century of chlorofluorocarbons (CFCs), principally in refrigeration (Held *et al.*, 1999, 396–397). The decisive evidence for the scale and immediacy of this threat came from scientists of the British Antarctic Survey (Rajan, 1997, 44–45), gathered between 1982 and 1984 and published in 1985. The complex process of initial international political response to this evidence, commercial haggling over, and subsequent enterpreneurial adaptation to, its implications by major producers of CFCs, and political bargaining between wealthier and poorer countries over distributing the costs of adjustment, was bound to take some years (Rajan, 1997, Chapters 3 and 4). But in retrospect, the time-span between the publication of the British Antarctic Survey team's article in Nature in May 1985, the signature of the Montreal Protocol restricting CFC use in September 1987 (Rajan, 1997, 54), and its coming into effect in an amended version late in the summer of 1992, in a form which took better account of the interests of the poorer countries, was remarkably brief. We do not know quite why the response was this speedy. The startlingly grim implications of the Antarctic data? The unambiguous source of the damage? The relatively small number of major producers of CFCs and the clear (if expensive) availability of means to replace them with a far less damaging alternative? But the combination of shock and available remedy does offer some insight into how we might hope to alleviate other equally clear but less imminent menaces at a less hectic pace, where the costs of doing so are not too forbidding.

Deforestation, and loss of biodiversity through this and many other means, have proved far harder to arrest. Assessing responsibility for each, and allocating the costs of even attempting to bring them to an end, have been bitterly politically contentious, both within many individual states, and between groupings of wealthier and poorer states across the world. The complexities of perception and ambivalences of sentiment evoked by each reach back as far as civilization itself, and are inextricable from the history of class or ethnic conflict in most human societies (Thompson, 1975; Cronon, 1983). With the massive human population growth of the last half century and its prospective extension into the next few decades, levels of deforestation, to which the English or Italians became accustomed several centuries ago, and which the subcontinent of South Asia has undergone over the last century, now prospectively threaten the great rain forests of West and Central Africa, and even in the end the Amazonian basin itself. The extension of agriculture and stock-raising at the expense of forest cover, so long seen as the least equivocal index of human advance, now appears not as a single unambiguous good, but a potentially ever less coherent sequence of increasingly wanton actions. The political impetus to persist with each remains extremely powerful; but the overall practical rationality of doing so is steadily harder to defend. No area of world trade today is as dominated by the political power of sinister and consequentially damaging interests as the agricultural exports of North America and the European Union, with their massive internal subsidization. The relation between markets and food supplies has been morally fraught throughout modern history; and even the most compelling case for laissez-faire in the field of food is hard to reconcile with the levels of market distortion locked into the routine politics of most long-established capitalist democracies. This is not an aspect of human social existence in the world today which any extant ideology articulates clearly and evaluates compellingly, though there is, of course, widespread and sometimes sophisticated understanding of the harms and benefits that flow from the bewildering variety of individual practices.

The most effective arguments for the imperative of preventing further deforestation are prudential, and center on its prospective impact on global warming, and hence on climate change. The gap between recognizing the force of the arguments and halting (or even reversing) deforestation is immense, and certain to remain for a long time as economically perturbing as it is politically challenging. But at least deforestation is a relatively salient phenomenon, something which could, in principle, in due course be tracked accurately by satellite camera (*see* Global Forest Watch, Volume 4). The loss of biodiversity is inherently more nebulous, and far harder to measure until it is already too late. The prudential arguments for the urgency of arresting it involve far more speculative judgements, many of them about future scientific advances, while the normative arguments for the same conclusion, stressing the enormity of eliminating natural differentiation itself, have little solid foundation in the great majority of extant human cultures, and receive scant tendential support from the spread of the industrialized economies and ever more commoditized forms of life. It is hard to be confident, in the case of plant, marine or animal life, that net loss of biodiversity will slow in the near future, and just as hard to believe that the domestic political judgement and diplomatic finesse of states today equip them to focus effectively on this issue and cooperate firmly and deftly with one another in responding to it (Rajan, 1997, Chapters 7 and 8).

The most politically interesting and potentially consequential dimension of ecological degradation so far identified is the process of global warming through the combustion of fossil fuels, and its prospective impact on climate across different human habitats. Whilst the scale and timing of disruption are thus far impossible to estimate accurately, it is striking how rapidly the levels of risk ultimately at stake, have come to be accepted, even by those with the clearest immediate stake in continuing

to deny them (Houlder, 1999a). In marked contrast with British governmental vacillation over the hazards presented by genetically modified food crops (Houlder and Wigton, 1999), and the collapse of the UN Cartagena meeting in February 1999 on the biosafety protocol in the face of US insistence on pressing its entitlement to export genetically modified crops under the rules of the World Trade Organization (1999), there now appears to be little coherent governmental opposition in international negotiations to the need to lower emissions of greenhouse gases and enhance the efficacy of energy use with some rapidity. This is certainly not an index of the limited scale or political importance of the interests which will suffer directly and immediately from any such adjustment. In each case, these could hardly be more extensive. What it reflects, above all, is the universality of the interest in having a viable habitat, the imponderability of the scale of risk in question, and the relative simplicity and obtrusiveness of the mechanism which will initiate the harm (however complicated its subsequent mediation proves to be).

Unlike older and starker preoccupations like desertification (where there has been extensive international coordination to limit the threat, under the auspices of the UNEP (Elliott 1998, 90–94), or shrinking or degenerating water resources (Houlder, 1999b), what drives home the significance of global warming is not its immediacy or concreteness, but the potential limitlessness of its incidence and the comprehensiveness of its scope. It is these two together which explain the density and tenacity of the diplomatic negotiations which led up to the UN Framework Convention on Climate Change of May 1992 and its signature at Rio, and which overrode the very limited practical gains of the Convention itself (Elliott, 1998, 68–69) and the sharp divisions of interest which had ensured these, to establish a far more definite (and perhaps even prospectively effective) set of mechanisms for addressing the issue a mere five years later in the December 1997 meeting which drew up the Kyoto Protocol (Grubb *et al.*, 1999). A core provision of the Kyoto Protocol is the system for trading permits for the provision of greenhouse gases, which is intended to redistribute the physical burden of limitation in such a way as to meet the agreed limits, rapidly and at the lowest net cost in individual welfare or economic growth foregone. Any process of bargaining and coordination which involves parties with highly unequal assets is likely to generate results which are disquieting on grounds of justice (Barry, 1989). But no large-scale political process of this kind can be conducted behind a veil of ignorance. To produce any measure of concrete agreement, and still more to secure agreements which stand any real chance of being implemented in practice, it is essential to identify outcomes which reflect a clear common interest, which is evidently more important than the necessarily even clearer conflicts of interest over how the costs of securing it are distributed between the parties. Only extended experience of trading emissions permits, in the context of an evolving international trading regime and a world economy whose dynamics are certain to remain highly erratic for the foreseeable future, will show whether the Kyoto Protocol has established a formula for adjusting global production over time to the need to lower fossil fuel consumption in the longer run.

What is already clear is that the Kyoto Protocol, even if observed, will at most slow the accumulation of greenhouse gases for many decades to come, and that the process of coordination is certain to remain arduous across the different forms through which it must be pursued – from individual national industries or nation states, through economic blocs like the European Union, the North American Free Trade Agreement (NAFTA) or ASEAN, to the global panoply of UN organizations. The unintended effects of policy instruments like national energy taxes on the international competitivity of high energy use industries such as steel show the indispensability of coordinating widely. The laborious and often opaque activity of diplomatic haggling throughout the global negotiations on climate change of the last two decades, shows the proliferating costs in time, patience and analytic effort in every further attempt to coordinate policies. Strong *a priori* grounds for doubting whether coordination in face of sufficiently discrepant structures of interest can be either possible or rational (Olson, 1965; Hardin, 1982, 1995; but cf Axelrod, 1997) must be offset by weaker inductive grounds for recognizing that a great deal of coordination does in fact sometimes occur. In the end, what does and will decide the degree of coordination is the internal process of political judgement itself, a process led by active cognitive interest, but also distorted throughout by personal folly and sometimes far from benign passions (Dunn, 2000).

What has emerged into politics with the agenda of global environmental change is an overwhelming new political challenge. The most myopic of us can readily see that this challenge is bound to intensify many old political problems, and not unlikely to impair some of our existing resources of organization and mutual confidence for dealing with many components of our familiar political predicaments. What is less easy to see is whether the challenge itself might, or could not, generate fresh resources, whether of organization or of mutual confidence, with which to try to confront it. Hardest of all is to judge how the balance between sharpening challenge, faltering institutions and weakening mutual confidence, and tentative genesis of new institutional structures and changed sensibilities and dispositions, is likely to come out over time. But even this is best seen in the end, less as a question about how to interpret the human world, than about how to change it for the better. It is not

a scientific question with an, as yet unknown, scientific answer, but a practical question which can be answered only in practice.

It will, of course, be answered by what we and our descendants prove to do, and fail to do. There is every reason to fear that it may be answered very badly, as, in a sense, it now turns out, it has been answered for most of recorded human history. Since, for the first time in that history, we now have good reason to believe that we hold the fate of our own species fully in our own hands, there is clear urgency to learn to answer it far better. This is a challenge not just to our moral imaginations and limited self-control, but to the very core of our practical good sense: our will and capacity to preserve ourselves individually and collectively over time. Above all, today and for the imaginable future, it is a challenge to our political judgement (Dunn, 1998).

The Environment and Violent Conflict

DANIEL M SCHWARTZ

University of Toronto, Toronto, Canada

Increasingly, violent con ict - and the potential for such con ict - is being linked to environmental problems such as water pollution, over- shing, deforestation, and global warming. Research suggests that it is developing nations that are most vulnerable to this environmentally induced con ict.

Environmental stress is rarely considered to be the sole factor in precipitating con ict, which can take the form of both con ict between and within nations. In many cases environmental stress is a relatively distant factor, acting in combination with other economic and social factors such as poverty and weak governments. In other cases, con ict breaks out when rival nations, or rival groups within a nation, battle for diminishing supplies of environmental resources. Although environmental stress is usually only one cause of con ict among many, the evidence suggests that it can play an important role, and that violence may be avoided by addressing environmental problems.

Interest in the linkages between environmental stress and violent con ict has grown rapidly in the last two decades. In part, this is because the end of the Cold War has shifted discourse on the issue of security in both academia and policy circles. Although traditional threats to security - such as conventional and nuclear war - still exist, there has been an increasing recognition that security is also tied to less apparent dangers such as chronic poverty, infectious disease, and the depletion and degradation of environmental resources.

INTRODUCTION: THE CHANGING NATURE OF SECURITY

In 1977, Lester Brown of the Worldwatch Institute published *Rede ning National Security*, a pioneering work, which argued that the most significant security dilemma facing humankind was an ever-widening gap between the supply of, and demand for, environmental resources (Brown, 1977). This idea challenged mainstream conceptions of security and launched a debate on the topic of redefining security that has grown increasingly sophisticated over the last two decades.

In the mainstream schools of thought that focus on the issue, security is (and always has been) largely synonymous with state security. In a world comprised of self-interested and calculating individuals, the state is seen as the purveyor of authority and security. Without the state, individuals would live in what 17th century philosopher Thomas Hobbes termed a state of nature, and life would be solitary, poor, nasty, brutish, and short. Moreover, mainstream security analysts believe that the greatest challenge to state security comes from outside the state in the form of military force or organized violence. The most effective means for a state to repel an outside threat of force is to engage the enemy with military force of its own.

Academics and policymakers who agitate for a redefinition of security, contest these assumptions made by mainstream analysts. Some proponents of redefining security argue that the focus of security should be shifted away from the state, and nearly all contend that threats to security should include non-military ones – especially environmental stress. These proponents champion the concept of environmental security to challenge the near monopoly that mainstream security analysts have held in the past.

Environmental security analysts that encourage a move away from state security, favor either a shift upwards to the global level, or downwards to the individual level. A shift upwards to the global level is encouraged by those who contend that environmental problems such as global warming and ozone depletion transcend national boundaries and highlight the oneness of a world divided along arbitrary and increasingly meaningless political boundaries. Those who favor a shift downward to the individual (or human) level, assert that environmental problems such as urban pollution often affect human wellbeing more than they affect an abstraction such as the state. Other environmental security analysts, however, do not favor a shift away from state security. They insist that as long as the state continues to be the central organizing principle in global politics, state security should continue to be the focus.

Although some environmental security analysts do not agitate for a movement away from state security, most maintain that non-military threats to security are at least as important as military threats. They point out, for instance, that the annual toll of individuals suffering from infectious diseases, such as the Ebola virus and AIDS, far outnumbers the global number of battlefield casualties in the last decade (Pirages, 1996, 13). In short, these analysts contend that security must not be measured only in terms of military might, but also in terms of economic wellbeing, social stability, and environmental health.

Environmental security analysts have made some tangible headway in their attempt to redefine security. At the national level, for instance, the US Department of Defense, in 1993, created the position of Deputy Under Secretary for Environmental Security. At the international level, the North Atlantic Treaty Organization and the United Nations Environment Programme have explicitly recognized the issue of environmental security (Schwartz and Singh, 1999; Gleditsch, 1997).

But efforts to redefine security have also been met with suspicion and outright scorn. Skeptics argue that proponents of environmental security are mere opportunists, dressing up environmental concerns in security garb, with the intention of shifting resources away from military budgets to environmental budgets. Moreover, critics contend that too broad a definition of security renders the concept meaningless for all intents and purposes.

But there is yet another way in which environmental stress and security may be inextricably linked. Recent research has discovered various ways in which environmental stress can lead to the outbreak of violent conflict. Environmental stress can contribute to resource shortages, which can provoke conflict between nations and induce conflict within nations. Environmental stress can also engender and interact with economic and social phenomena – such as poverty and weak governments – to create conflict between and within nations. These linkages are discussed in detail below. For our immediate purposes, however, it is important to note that even if we hold to a mainstream conception of security – in which military threats prevail – the environment-conflict nexus suggests that the environment can be an important component of security. If environmental stress can in fact contribute to violent conflict within and between nations, then even the staunchest of mainstream security analysts must recognize the importance of environmental issues.

ENVIRONMENT AND VIOLENT CONFLICT

The notion that disputes and violent conflict can erupt over access to environmental resources appears commonplace: international wars and civil conflicts have been fought over access to land and resources since time immemorial. Three factors, however, make modern-day analyses on environment and conflict novel. First, there has been a shift in focus from non-renewable resources such as oil and minerals, to renewable resources such as water, cropland, forests, and species. Most experts concur that conflicts over non-renewable resources will continue to erupt. The Gulf War, for instance, was fought, at least in part, over access to oil. But for the first time, renewable resources are being considered as systematic factors in the explosion of hostilities.

Second, modern-day analyses on environment and conflict emphasize the role of population growth in fostering environmental stress. Throughout this essay, I use the term environmental stress (or environmental problems) to indicate the degradation and depletion of renewable resources. Although I will not make explicit reference to it on every occasion, I consider population growth to be intimately connected to environmental stress. As a population grows, the demand on environmental resources increases; and as the demand on environmental resources increases, the abundance of the resource itself shrinks while the existing supply is often over-taxed. Although some demographers have recently predicted that population growth will actually begin to decline worldwide in approximately 50 years, there is also an overwhelming consensus that the global population will hit between 7.5 and 10.5 billion in the year 2050. With such large increases predicted for the near future, population growth will continue to be intimately connected to environmental stress.

Finally, as will be discussed in detail below, modern-day analyses on environment and conflict often focus on the manner in which environmental stress can combine with other economic and social factors to produce conflict. Whereas past analyses focussed solely on conflict over environmental resources, modern-day analyses also assess how the degradation and depletion of renewable resources can act in conjunction with social and economic conditions to produce conflict between and within nations.

In what follows, I examine the various ways in which environmental stress can precipitate violence. Before examining these linkages, however, I distinguish between wide-ranging environmental stress and localized environmental stress. By wide-ranging, I refer to environmental problems that are affecting the entire globe or large areas of the world simultaneously. Two prominent examples are global warming and depletion of the stratospheric ozone layer. By localized environmental stress, I refer to environmental problems that are affecting small areas of the globe at different times. Examples include deforestation and water pollution.

This distinction notwithstanding, it is important to emphasize the global nature of all environmental stress. The interconnectedness of the environment makes it likely that even the effects of localized environmental problems will spread beyond their initial boundaries. Water

pollution, for instance, can easily spread beyond the immediate boundaries of its inception through groundwater and tributaries. Moreover, global economic and social forces make it likely that the roots of localized environmental problems can be traced back to forces outside of the area immediately affected. Deforestation in many developing nations, for instance, is partly the result of growing demand for lumber and wood by-products in developed nations.

INDIRECT INTERNAL CONFLICT

Evidence to date indicates that environmental stress is most likely to result in conflict when it engenders and interacts with social and economic factors to produce conflict within a nation. Because the evidence for this type of conflict is abundant, and because the processes identified here will shed light on all of the various conflict types discussed below, I will spend a good deal of time explicating indirect internal conflict.

I consider this type of conflict to be indirect, because conflict does not arise over a particular environmental resource. Rather, the conflicts are often typical ones, including ethnic conflicts, class conflicts, revolutions, insurgencies, etc. But the cause of these conflicts can often be traced back, in part, to environmental stress.

Conflict is internal when environmental stress produces violence within the boundaries of a nation. The process that leads to conflict can often have cross-border dimensions, such as when cross-border migrations that are induced by environmental stress play a role in creating conflict. And, as noted above, local environmental stress itself is often the result of global environmental change and economic forces. Nevertheless, if the conflict itself is confined to within the perimeters of a particular nation, we can consider the conflict to be an internal one.

There are at least five pathways to indirect internal conflict that involve environmental stress: economic decline, migrations, social segmentation, erosion of civil society, and curtailment of the state. These pathways rarely work in isolation from one another. In most cases, the various roads to conflict are very complex and involve elements from a number of pathways working in synergy. To better understand the role that environmental stress plays in engendering conflict, however, it is useful to parcel out these pathways and examine each one individually before considering the ways in which they criss-cross one another to form the broader roads to conflict.

Economic Decline

Perhaps one of the most evident and widely cited social effects of environmental stress is economic decline. There are many types of environmental stress that can contribute to economic decline, including wide-ranging environmental problems such as global warming and stratospheric ozone depletion, as well as more localized environmental problems such as deforestation, water pollution, and over-fishing. Although environmentally induced economic decline can lead to general economic malaise in society, it is more likely to affect the poorer segments of society and thus widen the differential between rich and poor. This is because it is the poorer segments of society that are more likely to be highly dependent on environmental resources, and less able to buffer themselves from the effects of environmental stress (Homer-Dixon, 1999, 88).

It is essential to keep in mind that environmental stress is only one cause among many contributing to economic decline and widening income gaps. Nevertheless, it appears that it can be an important factor. Global warming, for instance, could lead to a rise in sea level and produce more frequent extreme weather events such as hurricanes and tornadoes. These events, in turn, could cause major property damage to coastal regions and result in the injury to, and/or loss of, human life. Global warming may also lower precipitation in some regions and yield pest infestations. These effects would strain the economic resources of local regions and nations. Myers (1993, 174), for instance, contends that global warming could cause the United States' grain belt to become unbuckled, with as much as half of the farmlands in the Southeast failing, California running out of water to irrigate its huge areas of cropland, and many of the country's woodlands and forests fading from the scene. Most analysts, however, including Myers, note that it is developing nations that will likely bear the brunt of global warming. For example, regions that are already plagued with fragile environments, such as the Sahel and the Indian subcontinent, could face severe droughts that significantly undermine their agricultural productivity.

Stratospheric ozone depletion can also induce conditions that lead to economic decline. For instance, by depressing immune systems, stratospheric ozone depletion can increase disease rates in humans and animals. Some experts suggest that recent increases in the occurrence of skin cancers and eye cataracts in the Southern Hemisphere are already attributable to depletion of the stratospheric ozone layer. Stratospheric ozone depletion can also adversely affect agricultural productivity. Studies suggest, for instance, that stratospheric ozone depletion could reduce crop yields by anywhere from 5% for wheat to 90% for squash. Finally, and perhaps most ominously of all, stratospheric ozone depletion can wreak havoc on entire ecosystems. Phytoplankton-based food chains in the sea, for instance, could be disrupted. If phytoplankton are affected, higher levels in the food chain – such as zooplankton and fish – would likely be affected as well (Myers, 1993, 166–167).

If these impacts from stratospheric ozone depletion materialize – increased disease rates in humans, declining

agricultural productivity, and ecosystem damage – government coffers would inexorably feel the pinch between increasing demand on national and regional health care systems, and decreasing revenues from agricultural and fishing sectors. Although developed nations would hardly be immune to the impact of stratospheric ozone depletion, it is again developing nations that would likely suffer the direst economic consequences because they often lack the infrastructure and economic flexibility to mitigate the impacts.

If the potential ramifications from global warming and stratospheric ozone depletion are sound in theory, there is little documented evidence to date that would support the connection between these wide-ranging environmental problems and economic decline. The socio economic effects of global warming and stratospheric ozone depletion, quite simply, have not yet begun to play themselves out in any systematic way, although there are indications that this is beginning to happen.

The link between more localized environmental stress and economic decline, conversely, has been evident for years. Many regions, especially in the developing world, are already feeling the financial sting of localized environmental stress.

Deforestation, for instance, has had particularly pernicious consequences for regional and national economies. Large-scale unsustainable logging practices may reap short-term rewards for a nation, but these logging practices can also sow the seeds of long-term economic decline once initial supplies are exhausted. Barber (1997, 53–54), for example, argues that Indonesia's unsustainable deforestation practices over the last three decades created huge amounts of wealth, but also sacrificed future profits that are now sorely missed by the nation's economy. Deforestation can also reduce the available supply of fuel wood – the wood that many people in developing nations are highly dependent upon for their daily energy requirements. As the supply of wood dwindles, prices rise, forcing poor families to spend an increasing portion of their budget on this resource. In Chiapas, Mexico, for instance, rapid deforestation of the Lacandon rainforest over the last two decades has deprived local citizens of much needed wood. The lack of fuel wood, in turn, has contributed to widespread poverty in the region (Homer-Dixon and Percival, 1996, 17–20). Finally, deforestation can foster silting, soil erosion, and desertification; change regional hydrological cycles and precipitation patterns; and decrease the land's ability to retain water during rainy periods. All of these effects limit agricultural productivity, cause damage to pivotal infrastructure such as roads and bridges, and reduce the hydroelectric capacity of rivers. Homer-Dixon (1999, 81–93) notes that in China, South Asia, Southeast Asia, and the Middle East, much cropland has been lost or degraded by erosion. And on the Filipino Island of Palawan, only half of the potential farmland is irrigable because of the hydrological effects of decreases in forest cover.

Water pollution has also created economic decline by limiting agricultural activity and fostering disease. These effects have been particularly acute in the Middle East. Homer-Dixon (1999, 90–92), for instance, contends that in Gaza, water aquifers have been salanized from over-pumping and severely polluted from agricultural run-off. The result has been damaged soil, declining crop yields, and severe reductions in potable water. Routine consumption of polluted water has led to widespread health problems in Gaza's Palestinian population, straining health care budgets and retarding economic development.

Finally, over-fishing has induced economic decline. Some developed nations have seen their economies eroded by the collapse of fisheries. Canada, for instance, has at various times imposed moratoriums on commercial cod fishing on the East Coast and severely restricted commercial salmon fishing on the West Coast. But once again, it is developing nations – especially regions that are highly dependent on their fisheries – which have been most affected by the depletion in fish stocks. For example, Lang (1995) traces regional and national economic decline in Kenya back to a combination of water pollution and over-fishing in Lake Victoria – a key body of water for the nation and a pivotal source of revenue for many citizens.

Migration

A second pathway from environmental stress to conflict is through migration. Wide-ranging and localized environmental stress, in conjunction with other social and economic factors, can induce movements of people within national borders as well as between nations. Sometimes large and spontaneous migrations are caused by environmental factors, such as floods, droughts, and locusts. Flooding in Mozambique and Madagascar during February and March, 2000, for instance, caused large and rapid movements of people in these African nations. The degradation and depletion of renewable resources, however, is often a distant cause of migration. It may, for instance, contribute to economic decline, which subsequently contributes to migration. Further, this type of environmentally induced migration rarely involves large and spontaneous upheavals of people. Rather, the migration occurs slowly over long periods of time. These two caveats notwithstanding, migration induced by the depletion and degradation of renewable resources can be an important pathway to conflict, especially in developing nations where people's livelihood is often tied intimately to these resources.

The availability of arable land is likely one of the most important factors contributing to migration. This is especially evident in developing nations where agriculture can constitute a sizeable portion of local economies. Of

course, it is not the availability of arable land *per se* that induces migration, but rather the economic prospects that correspond to this availability. A scarcity of arable land will create economic decline, which acts as a push factor and decreases the quality of life, thereby inducing migration. Moreover, the prospect of migrating to verdant regions, where land is not scarce, can create a pull factor by offering migrants an enhanced quality of life. Large in uxes of people can often lead to a host of new environmental problems in the migrants destinations, thereby perpetuating a cycle of environmental stress and migration.

A scarcity of arable land is often caused, in part, by environmental stress. Deforestation, in particular, can induce ooding, soil erosion, and deserti cation, which can then degrade the nutrient base needed for agriculture. Hazarika (1993) identi es just such a process in Bangladesh during the 1980s. By deforesting upstream areas in the Himalayas, downstream soil was exposed to rain and winds. Consequently, the ooding which naturally occurs in this area was signi cantly exacerbated, and land degradation ensued. Combined with rapid population growth, land degradation forced farmers to divide the remaining arable land into ever-smaller portions. As the prospects for farming became increasingly grim, Bengalis began to look across the border to the relatively plush lands in Northeast India. The result was a gradual movement of over 10 million Bengalis to Northeast India. Similarly, Renner (1996, 106) contends that massive deforestation and soil erosion played an important role in decreasing the agricultural productivity of peasants farming the highland areas in Ethiopia. As a result, large numbers of peasant farmers migrated to the Ogaden area in southeastern Ethiopia where the prospects for farming were perceived to be substantially better.

Environmentally induced land scarcity is not the only factor that can lead to economic decline and migration. Smil (1992, 17 19) posits that water and air pollution have engendered migrations from the interior provinces of China to the country s eastern and southern coastal regions especially coastal cities where prospects for earning a decent wage are widely considered to be far superior to those in the interior provinces. Similarly, Wegemund (1996, 307 311) points to a shortage of fuel wood (caused primarily by rapid deforestation) as well as a scarcity of water (caused in part by water pollution and in part by increasing demand on the resources) as two key environmental problems that have yielded signi cant migrations in Africa s Senegambian region.

Social Segmentation and Erosion of Civil Society

While studies on the linkages between environmental stress, economic decline, and migrations are quite common, the impact of environmental stress on social segmentation and civil society has yet to receive widespread attention. Homer-Dixon (1999, 96 98) demonstrates, however, that environmental scarcity can produce social segmentation by deepening divisions among ethnic, religious, and linguistic groups. Homer-Dixon also shows how environmental stress can fray the web of networks in society made up of nongovernmental organizations, unions, and community service organizations. These societal networks form the core of civil society, and are key to mediating the relationship between individuals and the state. Just as migrations can occur as a result of both environmental stress and economic decline, social segmentation and the erosion of civil society can occur as a result of a complex interaction between environmental stress, economic decline, and migrations. Again, environmental stress in these cases is a distant but potentially important cause.

Homer-Dixon argues that environmental stress can contribute to a scarcity of resources, which can then deepen the fault lines between those who pro t from those scarce resources and those who are impaired by the scarcity. Environmental stress, he argues, encourages competition among groups for control of resources critical to survival and prosperity, and it encourages resource-dependent groups to turn inward and to focus on narrow survival strategies. This competition over resources often takes place against a backdrop of economic decline, which is also, in part, the result of environmental stress. Moreover, the vicious cycle between poverty and migration, discussed above, can also play a role by increasing competition for ever-scarcer resources in recipient nations.

Critical to his analysis of social segmentation, is what Homer-Dixon has called *resource capture*. Resource capture occurs when environmental stress and population growth combine to encourage powerful groups within a society to shift resource distribution in their favor. By shifting the resource distribution in their favor, these powerful groups capture the resource and prosper from speculation and monopolistic pro ts. Although this process increases the wealth of powerful groups in society, it also produces a signi cant scarcity of environmental resources for weaker and poorer groups in society. As competition for resources increases, tensions between rival groups within the poorer segment of society are heightened. Moreover, tensions are often in amed by powerful group leaders, who use divide and conquer tactics to solidify their clout.

Social segmentation is intimately tied to the erosion of civil society. When a society segments and the various factions turn inward, the myriad societal networks that are crucial to the functioning of a society can quickly disappear. Researchers have argued convincingly that these networks are crucial to the functioning of a society because they help to build bonds of trust between people of differing ethnic, religious, and linguistic backgrounds. Moreover, as these networks erode, civil society quickly weakens, thereby

reducing the ability of marginalized people to articulate their demands on the state.

These processes of social segmentation and erosion of civil society are illustrated by Homer-Dixon's analysis of events in South Africa from the mid 1980s to mid 1990s. With the collapse of Apartheid, large numbers of blacks began to migrate from their homelands – which often suffered from severe environmental deterioration and poverty – to the country's urban centers. The migrants settled in peripheral and ecologically sensitive lands in the urban centers, such as hillsides and river valleys. The huge influx of people onto these lands induced further environmental problems such as water pollution and deforestation. These environmental problems, in turn, promoted economic hardship and provided a window of opportunity for powerful warlords – local leaders who control their own paramilitary – to seize control of the remaining resources. With scarce resources firmly in their hands, warlords were able to illicit the support of their local groups, which were often divided along ethnic lines (e.g., the Zulu and Xhosa) and family-based lines. The warlords exploited these societal divisions in order to promote their own interests. Consequently, competition between local groups increased, social segmentation solidified, and the societal networks that form the core of civil society were severed.

Curtailment of the State

The fifth and final pathway from environmental stress to conflict is through curtailment of the state. Environmental stress, in conjunction with other social and economic variables – including economic decline, migration, and social segmentation – can curtail key institutions of the state. The state generally consists of the group of institutions in society that wield authority and make binding rules for the nation, or regions within a nation.

Homer-Dixon (1999, 98–102) identifies at least two ways in which environmental stress can curtail key state institutions. First, environmental stress may increase the financial burden on the state. Environmentally induced economic decline, for instance, may compel the state to increase the size of subsidies; and environmentally induced migrations into urban centers can greatly augment infrastructure requirements such as sewers and water piping. For instance, Homer-Dixon argues that to deal with acute water scarcity in China – induced by a combination of pollution and population growth – the state must spend huge sums on new infrastructure such as wells, dams, canals, pipelines, and irrigation systems; and it must build large facilities to control industrial and municipal pollution.

Second, environmental stress can affect state elites, such as high-ranking officials and business people with close connections to the upper echelons of decision-making in the state. In particular, environmental stress can threaten the incomes of elites that depend on the extraction of an ever-degrading and depleted resource base. Consequently, these elites may turn to the state for compensation, or they may act to block institutional reforms that would distribute more fairly the costs of rising scarcity. Alternatively, environmental stress can increase the scarcity and value of resources, thereby generating opportunities for powerful coalitions of elites to gain control of these resources in a process similar to that of resource capture, described above. As these elites become increasingly powerful, they can challenge the authority of the state. Increasing land scarcity in the southern Chinese province of Guandong, for instance, has created huge profits from land sales, inducing developers and corrupt officials to illegally control these revenues and ignore dictates from the state in Beijing.

The Roads to Conflict

The five pathways from environmental stress to conflict – economic decline, migrations, social segmentation, erosion of civil society and curtailment of the state – rarely work in isolation from one another. The pathways are often complex, and involve shared elements. For example, social segmentation can involve both economic decline and migrations, both of which can be induced by environmental stress.

But how do these pathways actually interact to produce conflict? Here the complexity gets ratcheted up another level. There simply are no necessary or sufficient causes of conflict, and there is no single pathway to conflict that one can consistently discern. Nevertheless, by mapping out the criss-crossing pathways and their complex interactions, one can begin to make out some broader roads to conflict. These roads can be traversed along many different combinations of pathways. Figure 1 illustrates the various combinations. Below I discuss a number of these possible combinations and provide some examples to illustrate the processes.

One possible road to conflict involves both economic decline and curtailment of the state. As noted above, environmentally induced economic decline rarely affects an entire society or nation uniformly. Rather, it usually widens the gap between rich and poor, which then fosters grievances among the poorer segments of society. If this element of society perceives the state to be the over-arching cause of the economic injustice they are experiencing, they might initiate conflict with the state in an attempt to reverse their plight. These challenges to the state can assume various forms, including armed rebellion, guerrilla warfare, terrorism, and *coups d'état*.

But challenges to the state are likely to occur only if challengers perceive the state to be vulnerable. Conflict with the state, then, is most likely to take place when a segment of society is aggrieved and when the opportunity for reversing

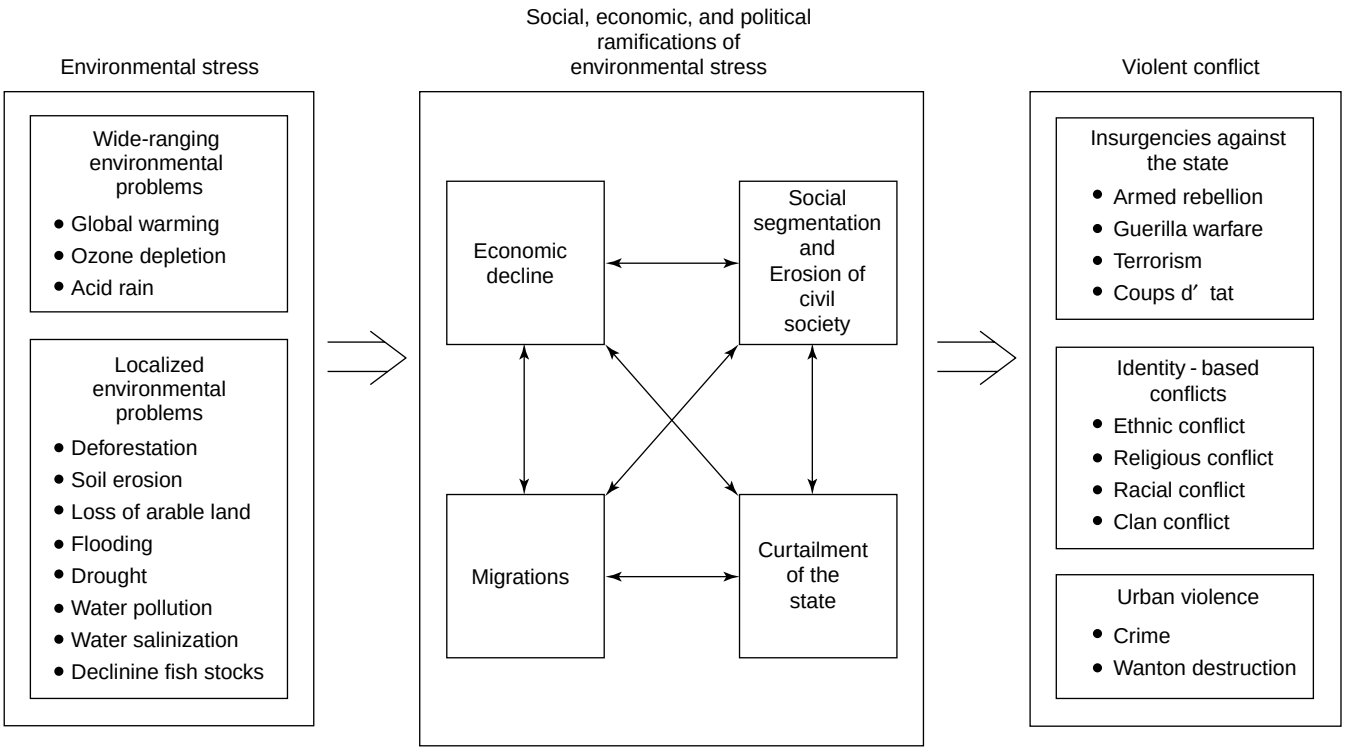

Figure 1 The roads to conflict

their status is present. Environmental stress, as discussed above, can influence both of these factors by contributing to economic decline and curtailment of the state.

Suliman (1992) contends that the road to conflict in Sudan has followed these pathways. Since 1983, violent attacks by the Sudan People's Liberation Army have been taking place against Sudanese state institutions, as well as businesses associated with the state. A majority of analysts trace the roots of this conflict to development projects conducted by the state – controlled largely by elites in Northern Sudan – in which resources are extracted from the South. Many Southern Sudanese consider these development projects to be a form of economic exploitation that would enrich only the state and its cronies.

Suliman, however, traces the roots of this conflict back further than most analysts. He contends that state-led development projects in Southern Sudan were initiated, in part, because deforestation and an increase in large-scale mechanized farming had induced desertification and land degradation in the northern regions of the country. Economic decline in Northern Sudan not only compelled the state to look south, but also strained their financial resources. Given the grievances of Southern Sudanese, and the compromised power of the state, many Sudanese have supported and participated in violent attacks against state institutions.

Another possible road to conflict involves economic decline, migration, and social segmentation. As discussed above, environmental stress can contribute to economic decline which, in turn, can engender small-scale but persistent migration. When migrants enter a new territory, they often upset the existing political balance and consequently deepen divisions in society. The result can be a society consumed by conflict.

The type of violence that this combination of events can trigger is often different from the conflicts discussed above, which featured attacks directed against the state. When social segmentation sets in, conflicts between identity-based groups are more likely to result. The identities upon which these groups are based include race, language, religion, and lineage.

Events in Northeast India during the 1980s illustrate this process. As discussed above, Northeast India received millions of Bengali migrants during the 1980s. These Bengali migrants were driven to the Indian states of Assam and Tripura, in part by environmental stress and economic decline. In Assam, Bengali migrants were perceived as economic competitors and religious outsiders. Moreover, Bengali migrants shifted the balance of political power by developing significant influence in local institutions. As a result of these processes, social segmentation hardened between the predominantly Hindu Assamese and the primarily Muslim Bengalis. More than 4000 lives were lost in ensuing violence between 1979 and 1985. In Tripura, a similar series of events created small-scale but persistent

violence between identity-based groups that continues to the present (Homer-Dixon, 1999, 141–142).

A final example of a possible road to conflict involves all of the pathways identified above – economic decline, migration, social segmentation, erosion of civil society, and curtailment of the state. This combination of processes can be especially pernicious when the migration involves large movements of people from rural areas to urban centers. Violence in these cases may not only take the form of insurgencies against that state and identity-based conflict; it can also take the form of urban violence that includes crime and wanton destruction. Because rapid urbanization is a characteristic common to many developing nations today, this process is especially salient.

Events in South Africa during the 1980s and 1990s illustrate this process. As described above, environmental stress in South Africa induced rural–urban migration, which combined with further environmental stress and economic decline to engender social segmentation. As a result of this social segmentation in South Africa's urban centers, societal networks were eroded or simply unable to take hold in the first place. Compounded by increasing demands on the state and a decreasing ability of the state to meet these demands, a number of urban centers in South Africa – most notable in the Johannesburg and KwaZulu–Natal regions – began to experience widespread political and criminal violence that persists today.

Homer-Dixon (1999, 164–166) contends that Pakistan has traveled a similar road to conflict. In Pakistan, water pollution, deforestation, and soil erosion have engendered economic decline and large movements of rural–urban migration. In Karachi, Pakistan's largest urban center, the massive influx of people has created urban slums that suffer a chronic shortage of basic urban amenities such as potable water, garbage disposal, and electricity.

This squalor and shortage of basic amenities, has induced resource capture – the process identified above whereby local group leaders gain control of a resource and prosper from speculation and monopolistic profits. In Karachi, this process has manifested itself in local mafias that obtain water from illegal hydrants or from poorer districts in the city and then sell it for exorbitant profit – often to the very people from whom the water was pilfered. This process of resource capture has not only furthered economic decline, but has also hardened social segmentation between Karachi's many competing ethnic groups, and eroded many of the societal networks that make up the city's civil society.

Underpinning all of these factors are crippled state institutions that cannot meet the increasing demands of the urban populations. Environmental stress has not only reduced Pakistan's state revenues but has spurred rural–urban migration that has simultaneously increased financial demands on local and national governments. Moreover, corruption and cronyism plague both national and local governments. With institutionalized channels of protest and action stymied, Pakistani loyalties and allegiances have become increasingly localized and social segmentation has further solidified.

The result of the interaction of all these pathways to conflict has been increasing urban violence. This violence has taken the form of all three types of conflict described above, including urban violence (e.g., rising crime rates), ethnic-based violence (e.g., conflict between the Punjabis, Pathans, and Sindhi ethnic groups), and violence directed at the state (e.g., attacks on the Karachi Electricity Supply Corporation).

INDIRECT INTERNATIONAL CONFLICT

Just as environmental stress can engender and interact with social, economic, and political factors to produce conflict within nations, a similar process can lead to conflict between nations. I call these conflicts indirect international conflicts.

International conflict between El Salvador and Honduras in 1969 involved some of the processes identified above. On July 14th, 1969, El Salvador launched an invasion of Honduras, commencing a battle that has been coined the Soccer War, because hostilities were launched immediately following a series of hotly contested World Cup matches. The conflict lasted only 100 days, but claimed the lives of several thousand individuals, turned 100 000 into homeless and jobless refugees, and inflicted severe economic losses on both nations.

Although many pundits have blamed the outbreak of conflict on a bitter rivalry cultivated during the World Cup soccer matches, Durham (1979) shows that environmental stress was one of the key underlying factors contributing to this international war. Deforestation and soil degradation, in conjunction with rapid population growth, forced landless peasants in El Salvador to migrate to Honduras, where many poor Hondurans were already struggling with their own scarcity of arable land. Large landowners in Honduras, who had previously been held responsible by poor Hondurans for their economic plight, successfully redirected blame onto the newly arrived El Salvadoran migrants. Hondurans reacted by expelling the El Salvadorans, which then prompted the government of El Salvador to officially close its borders to Honduran refugees and eventually declare war on its neighbor.

Molvoer (1991) contends that a similar process of environmental stress and migration combined to produce conflict between Somalia and Ethiopia in 1977–1978. Overgrazing induced widespread deforestation and desertification in Somalia, which prompted large migrations of Somali pastoralists into Ethiopian territory. The migrations brought the Somali pastoralists into increasing competition with Ethiopian groups dependent on local resources.

The bitter competition between these groups fuelled tensions between Ethiopia and Somalia that eventually found its outlet in armed conflict between the nations.

These two cases suggest that environmental stress – especially localized environmental problems such as deforestation and soil degradation – can contribute to conflict between nations in much the same way that environmental stress can contribute to internal conflicts. Just as with the internal conflicts described above, it is developing nations that are most at risk of succumbing to these forces, because these nations are often highly dependent on environmental resources and lack the ability to mitigate the effects of environmental stress.

Developing nations, however, may not be the only nations at risk of environmentally induced international conflict. With the onset of wide-ranging environmental problems such as global warming, acid rain, and stratospheric ozone depletion, the spectre of international conflict that involves developed nations are portrayed as increasingly likely scenarios.

Lipschutz and Holdren (1990, 126–129) argue that, to date, the connection between environmental stress and international conflict has been weak, because localized environmental stress tends to affect the offending country more than any other nation. The damage incurred from this localized environmental stress has only rarely been sufficient to evoke a significant shift in a nation's conduct in the international arena. With the onset of environmental problems such as global warming, however, these dynamics may shift. Wide-ranging environmental stress threatens to produce unprecedented magnitudes of change: change that could foment large social and economic upheavals that inexorably drag developed nations into the fray. For the time being, of course, the potential for indirect international conflict that involves developed nations is based on reasoned conjecture rather than empirical evidence. Nevertheless, the scenarios conceived by some analysts are not beyond reason.

Perhaps the most apocalyptic scenario sees hemispheric conflict between developing nations in the South and developed nations in the North. The most common underlying environmental cause in this scenario is global warming. Although the impact of global warming may be gradual, the possibility of non-linear effects remains. If global temperatures pass a certain unknown threshold, for instance, changes in the planet's physical systems may be rapid and advance at a greatly increased magnitude. The grave scenarios involving hemispheric conflict sometimes draw on the potential for these non-linear effects of global warming.

Gleick (1989, 338) notes that global warming could affect key goods and services such as freshwater availability and food productivity. The societal impacts of these climatic changes, he writes, will be widely distributed, but they are likely to be felt far more severely by poorer nations, posing important and still unresolved questions about equity, fairness, and international environmental ethics. Similarly, Lunde (1991) contends that diplomatic disputes over responsibility for the generation of greenhouse gas emissions, as well as disputes over the potential ramifications of global climatic change, are likely to play into already-existing tensions between southern and northern nations. And Renner (1996) asserts that the politics of global warming is quickly shaping up as a dispute between the industrialized North, accounting for the bulk of emissions, and the South, which perceives itself to be a victim of global warming. While all three aforementioned analysts reject the notion of an all-out international conflict between North and South, they caution that global warming is an issue that can cause tensions between these hemispheric counterparts to rise steeply, increasing the likelihood of such violence.

Another route to conflict between northern and southern nations is through large-scale migrations and dislocations of people. Localized environmental problems, such as soil degradation and over-fishing, can cause small-scale but persistent migrations in developing nations. Some analysts contend that wide-ranging environmental problems such as global warming, coupled with rapid population growth and increasing disparities in wealth, could induce large-scale migrations from the developing to the developed world. Although small-scale migrations from the developing to the developed world already exist – migrations from North Africa to Europe, for instance, are common – wide-ranging environmental problems could exacerbate this process. Large-scale migrations could increase tensions between northern and southern citizens, and eventually induce hemispheric violence.

Renner (1996, 109–112) notes that citizens in many developed nations have become fearful that they are now being invaded, not by armies and tanks, but by migrants who speak other languages, worship other gods, belong to other cultures, steal their jobs, and threaten their way of life. Many industrialized nations, including the United States, Germany, and France, have witnessed significant domestic movements to curb the growing tide of refugees pounding at their borders on a daily basis. The spectre of massive influxes of people from the developing nations to developed nations elevates the possibility of the rest of the world against the West.

Other scenarios for international war envisage regional wars between developing nations and developed nations, as well as between developing nations. Again, wide-ranging environmental stress is predicted to be the catalyst of such wars, especially given the potential for non-linear effects. Myers (1993, 118–121), for instance, forecasts a potential downside scenario for the Indian Subcontinent, where global warming produces chronic shortages of food and water. These conditions aggravate tensions between India

and Pakistan, and eventually escalate into nuclear threats and hostilities. Similarly, Myers (1993, 146–148) downside scenario for the Americas sees huge numbers of Mexicans illegally migrating into the United States because of resource shortages, disease, and chronic poverty caused by global warming. The massive influx of illegal migrants then compels the United States to invade its southern neighbor in an effort to cut off the routes traveled by the migrants.

DIRECT INTERNATIONAL CONFLICT

If environmental stress may contribute indirectly to international conflict, it is the potential for direct international conflict that has garnered the most attention from scholars, government officials, pundits, and the general public alike. By direct conflict, I refer to violent hostilities that arise when two or more parties vie for control and/or access to environmental resources. In these instances, two or more nations engage in conflict over particular renewable resources in the same way that nations have fought wars in the past over non-renewable resources such as minerals and oil.

There are a number of renewable resources that could potentially elicit international conflict, such as cropland, fisheries, and forests. Indeed, international incidents over fisheries have already taken place. In 1995, for instance, a Canadian warship fired shots across the bow of a Spanish trawler, in a feud between the two nations over fishing rights along Canada's east coast.

It is the increasing competition over access to water resources, however, that constitutes the greatest threat of direct international conflict. Access to freshwater resources—lakes, rivers, and groundwater aquifers—is perceived by many to become the most important *casus belli* of the 21st century. Government officials have long made portentous claims about the advancing threat of water wars. In 1979, for instance, Egyptian President Anwar Sadat declared, "The only matter that could take Egypt to war again is water." In 1990, Jordan's King Hussein made similar declarations. Academics studying the issue have made equally portentous claims about the potential for conflict over water. Cooley (1984, 3), for example, contends that "Long after oil runs out, water is likely to cause wars, cement peace, and make and break empires." And Starr (1991, 19) argues that "Water security will soon rank with military security in the war rooms of defense ministries."

Water attracts such widespread attention as a potential *casus belli*, because this resource is a mainstay of life. Gleick (1998, 3) notes that freshwater is integral to all ecological and societal activities, including the production of food and energy, transportation, waste disposal, industrial development, and human health. Yet the availability of freshwater resources is declining significantly in many regions in the world. As population growth heightens the demand on water resources, water pollution and climatic change are combining to simultaneously decrease the supply. If annual water availability drops below 1700 m^3 per person, domestic self-sufficiency becomes almost impossible. Gleick estimates that there are already over two dozen nations that fall below this threshold, including nations in Africa, the Middle East, Asia, and the Caribbean.

Moreover, freshwater resources do not respect the political boundaries created by humankind. Gleick estimates that more than half the land area of the world, and perhaps 70% of inhabitable land areas, is in an international watershed where river flows or lakes are shared. And he notes that over 220 river basins are shared by two or more nations. Furthermore, these water resources are neither distributed nor shared equally. In the Nile river basin, for instance, Egypt is endowed with a renewable supply of just 1.8 $km^3\ year^{-1}$, but extracts as much as 55.1 $km^3\ year^{-1}$—far more than their renewable supply. In the same river basin, Ethiopia is endowed with a renewable supply of 110 $km^3\ year^{-1}$, but extracts only 2.2 $km^3\ year^{-1}$.

Conflicts over water resources have already been documented. Indeed, Gleick notes that water wars are nothing new to human history. Forty-five hundred years ago, the control of irrigation canals was the source of conflict between the states of Umma and Lagash in the ancient Middle East. Twenty-seven hundred years ago, Assyria and Arabia clashed over the control of water wells. In the modern era, Israel and Syria have engaged in international conflict over water resources on at least two occasions. In 1965–1966, Syria tried to divert headwaters of the Jordan away from Israel, prompting Israel to attack the Syrian diversion facilities. And the 1967 Yom Kippur War in the Middle East was initiated, in part, because of disputes between Israel and Syria over the Jordan River.

With increasing environmental stress, there is a fear that conflict over water will become much more frequent in the near future. There are already many disputes over water resources that threaten to boil over into conflict. In the Middle East, the issue of water scarcity remains largely unresolved. An agreement between Israel and Syria over access to the waters of the Banias River, for instance, is still on the bargaining table. Jordanian concerns about Syrian dams on the Yarmouk River also remain unresolved.

But the spectre of conflict over water is not unique to the Middle East. In Europe, Czechoslovakia and Hungary nearly came to blows in 1992, because of a dispute over the construction of a dam and the diversion of waters on the Danube River. In Africa, Bostwana, Nambia, and Angola have disputed access to the shared waters of the Chobe River since the 1980s. In Asia, Cambodia, Laos, Thailand, Vietnam, and China have all engaged in disputes over the waters of the Mekong River. In South America, Ecuador and Peru engaged in small-scale armed skirmishes in 1995, in part because of disagreement over the control of the

headwaters of the Cenepa River. And in North America, Mexico and the United States continue to vie for control over the waters of the Rio Grande.

Despite growing fears that environmental stress could exacerbate water resource conflicts, some experts on environment and conflict maintain that these scenarios are based more on hyperbole than theoretical and empirical strength. Homer-Dixon (1999, 139), for instance, contends that international wars over river water are likely only when a narrow set of conditions hold: The downstream nation must be highly dependent on the water for its well-being; the upstream nation must be able to restrict the river's flow; there must be a history of antagonism between the two nations; and the downstream nation must be militarily much stronger than the upstream nation. He argues that these restrictions explain why international disputes over river water have only rarely escalated to international armed conflict.

Others argue that social and economic forces mitigate the threat of water wars. The potential for international conflict over water resources is eased, for instance, by global awareness of the interconnectedness of environmental issues, the expansion of economic interdependence, the involvement of international organizations, the evolution of international law in the field of transboundary water resources, and the potential for new technologies that relieve environmental stress.

DIRECT INTERNAL CONFLICT

Just as nations may clash over renewable resources, populations within nations may likewise come into conflict. Although direct internal conflict may occur over water, other renewable resources such as fisheries and arable land may also be sources of tension.

Compared to international conflicts over water, the threat of direct internal conflict has received very little attention in academic and policy circles. This is not entirely surprising, given that nations often contain relatively robust legal/institutionalized mechanisms for resolving disputes that occur within national boundaries, whereas these mechanisms are often relatively impotent in the international system.

Nevertheless, conflict over resources can occur (and has occurred) within national boundaries. The mechanism that ignites these conflicts is much the same as that for direct international conflict. When a resource becomes increasingly scarce within a nation, tensions may rise between groups that are competing for these resources. Environmental stress can contribute to the scarcity of resources. Population increase, for example, may increase the pressure on available arable land, while deforestation and soil degradation may decrease the supply of this arable land.

Groups that compete for these resources may be divided in a familiar way along ethnic, religious, or linguistic lines. Alternatively, these groups may be divided along vocational or professional lines. Loggers, for instance, may come into conflict with naturalists over the preservation of forests. Conflict can also occur between competing groups within a given vocation. Indigenous loggers, for example, could clash with non-indigenous loggers vying for the same forestry resources.

Developing nations are once again the most vulnerable to direct internal conflict. This is because these nations are often characterized by deep fault lines between competing groups, and because they often lack sufficient legal/institutionalized mechanisms for dealing with disputes between competing groups. Gleick (1998, 5–6) notes, for example, that for much of the 1970s and 1980s, India's Karnataka and Tamil Nadu peoples clashed over irrigation rights to the Cauvery River. A 1991 Interim Order handed down by the Cauvery Waters Tribunal – an institution set up by the state of India to resolve the ongoing dispute – only exacerbated tensions between these two groups, resulting in the deaths of over 50 people.

Although developing nations are the most susceptible to these types of internal conflicts, developed nations are not entirely immune. In the United States, for instance, the Los Angeles Valley aqueduct was repeatedly bombed in 1924 by a group of farmers perturbed that water was being diverted from their communities to urban centers in Southern California. The same region almost witnessed conflict in 1935, when the state of Arizona came to the brink of conflict with the state of California over plans for construction of the Parker Dam and subsequent diversion of water from the Colorado River (Gleick, 1998, 5). More recently, in 1999, native and non-native fishers on the East Coast of Canada clashed on several occasions, after the Supreme Court of Canada granted natives the right to fish year round for lobsters.

CONCLUSIONS: RESEARCH DEBATES AND POLICY IMPLICATIONS

The evidence presented above appears to highlight a disturbing trend in the international system. Increasingly, violent conflicts are being linked to the depletion and degradation of renewable resources. These conflicts may take the form of violent clashes between and within nations over particular renewable resources such as freshwater and fish stocks. Or the degradation and depletion of renewable resources may engender and interact with other economic and social factors – such as poverty and weak states – to foster conflict between and within nations. Environmental stress is almost never the only factor leading to conflict. Nevertheless, it can be an important one.

Although copious evidence exists to support the environment-conflict linkages, a number of theoretical and methodological criticisms have been leveled at the research, calling into question the validity of existing evidence on the environment-conflict nexus. I will not offer a comprehensive review of the controversies here. Rather, I will briefly highlight a few criticisms that my colleagues and I have dealt with in detail (Schwartz *et al.*, in press). These criticisms deal with issues that I consider the more pertinent ones under contention.

One of the most important theoretical criticisms of environment-conflict research is that linkages between environmental stress and violence are overstated, because humanity shows astonishing capacity to adapt to environmental problems. Markets stimulate human inventiveness and commerce that open up new sources of scarce resources, encourage conservation, and create technologies that allow substitution of relatively abundant resources for scarce ones. Critics contend that environment-conflict researchers have failed to consider these adaptive processes in their theoretical models.

Although adaptive processes certainly operate in many cases, societies often fail to adequately adjust to environmental stress. This is especially true for many developing nations, where institutions and markets can be weak and inflexible. Moreover, environmental stress itself can have debilitating effects on some economies, societies, and social groups. It is for these reasons that developing nations are more susceptible than developed nations to the social manifestations of environmental stress.

Environment-conflict research is also criticized on theoretical grounds for neglecting to consider the role that social phenomena play in the creation of environmental stress. Critics contend that the causal arrow that traces a route from environmental stress (e.g., soil degradation) to social and economic phenomena (e.g., migration and poverty) through to conflict (e.g., ethnic strife) is misleading, because environmental stress itself is caused in large part by social and economic factors. They argue, therefore, that the causal arrow should begin with social and economic phenomena.

There are at least three reasons why the causal arrow can begin with environmental stress. First, environmental stress is not only influenced by social variables like institutions and policies; it can itself affect these institutions and policies in harmful ways. This is the case when shortages of a renewable resource, such as cropland or forests, motivate elites to seize control of the resource's remaining stocks (the process of resource capture, explained above). In other words, we should not assume that social variables are completely independent and external starting points in the causal chain; it turns out that they can be affected by environmental scarcity, sometimes negatively. Second, the degree of environmental stress a society experiences is partly a function of the particular physical characteristics of the society's surrounding environment. These characteristics are, in some respects, independent of human activities. For instance, the vulnerability of coastal aquifers to salt intrusion from the sea and the depth of upland soils in tropical regions are physical givens of these environmental resources. Third, once environmental stress becomes irreversible – as when most of a country's vital topsoil washes into the sea – then the stress is, almost by definition, an external influence on society. Even if enlightened reform of institutions and policies removes the underlying social causes of the stress, it will remain a continuing burden on society – because the environmental stress itself is irreversible.

Aside from these important theoretical criticisms, environment-conflict researchers have also faced methodological criticisms. At issue in these methodological critiques are key issues pertaining to causation – i.e., the notion that one or more factors can cause an outcome to occur. The concept of causation has been debated in philosophical circles for hundreds of years. Although some consensus has emerged on how social scientists can show causation, the issue has hardly been resolved with any finality.

In order to show causation, mainstream social scientists favor quasi-experimental methods, in which potentially confounding variables are controlled and cases are selected in a random manner. The single case-study method neither controls for confounding variables nor selects cases in a random manner. Consequently it is widely perceived to be flawed by mainstream social scientists. Critics contend that because environment-conflict researchers have used the single case-study method rather than the quasi-experimental method to gather evidence, they are not able to make legitimate claims about causation.

My colleagues and I argue that the single case-study method in fact plays an important role in complementing the quasi-experimental methods preferred by mainstream social scientists. In order to demonstrate this, we draw on a distinction between causal effect (i.e., the impact that one variable has on another variable) and causal mechanism (i.e., the linkage between two or more variables). We argued that both causal effect and causal mechanism are essential to showing causation. Although quasi-experimental methods can estimate causal effect, they say little about causal mechanism. The single case-study method, on the other hand, can trace casual mechanisms but can not estimate causal effect.

We argue that research to date on environment and conflict has demonstrated the causal linkages between environmental stress and conflict (i.e., causal mechanism), but has not yet determined the degree to which environmental stress plays a role relative to other factors in the generation of conflict (i.e., causal effect). We conclude that a next crucial step in environment-conflict research is to estimate the causal effect of environmental stress.

While theoretical and methodological debates surrounding environment-conflict research continue in academic circles, at least some policymakers in foreign policy circles have begun to incorporate the research into their agenda. The US Central Intelligence Agency (CIA), for instance, has conducted a State Failure Task Force Report on the relationship between environmental stress and the outbreak of violent conflict such as revolutions, ethnic strife, and genocides (Esty *et al.*, 1999). And the Canadian counterpart to the CIA, the Canadian Security Intelligence Services (CSIS) has also recognized the linkages between environmental stress and violence (Gizewski, 1997).

For some, interest by the CIA and CSIS in environment-conflict research has only confirmed their worst fears: that by including environmental issues in debates over security, actions pertaining to the environment may become increasingly militarized. Although these fears may have some basis, environment-conflict research does suggest that if policymakers want to mitigate conflicts and enhance security in the future, they must pay attention to the state of the environment.

Development and Global Environmental Change

WOLFGANG SACHS

Wuppertal Institute for Climate, Energy, Environment, Wuppertal, Germany

The notion of development, offering language to the desire of many nations for justice and dignity, has been a powerful idea forcing global environmental change. The article traces the rise and decline of the development idea over the past 50 years. It attempts to uncover the concept's many layers of meaning as they built up during post-war history; it exposes the bitter legacies - socially, culturally, environmentally - which have been left behind by this period; and it points to the recent transition from development to globalization. Finally, some prospects are sketched out for achieving more equity outside the framework of conventional development.

HISTORY

The rise of epochs often go unnoticed, but the dawning of the development age occurred at a precise date and time. On 20 January 1949, President Harry S. Truman, in his Inaugural Address to Congress, dubbed the home of more than half the world's people underdeveloped areas. This was the first time that the word *underdevelopment* (OED, 1989, XVIII, 960), which was later to become a key category ordering global relations, was used by a prominent political figure. Truman, after drawing a sharp line between democracy and communism in the first part of his speech, directed the attention of his audience to the Southern Hemisphere with the following words:

> Fourth, we must embark on a bold new program for making the benefits of our scientific advances and industrial progress available for the improvement and growth of underdeveloped areas. More than half the people of the world are living in conditions approaching misery. Their food is inadequate. They are victims of disease. Their economic life is primitive and stagnant. Their poverty is a handicap and a threat both to them and to more prosperous areas. For the first time in history, humanity possesses the knowledge and the skill to relieve the suffering of these people.
>
> (Truman, 1949)

With these high-flying words of the Point Four Program, the development age, the particular period in world history following the colonial era, was opened (to be superseded some forty years later by the globalization age). In this period, the relationship between Europe/America and the rest of the world was being shaped by specific assumptions about time, geographical space, and relevant social actors. These assumptions came to frame the development discourse; they stand in continuity and contrast with the assumptions of both the earlier colonial and the later globalization periods.

Linear Global Time and the Rule of Gross National Product (GNP)

In the light of the concept development , all peoples on the globe appear to move along one single road. The lead runners show the way; they are at the forefront of social evolution, indicating a common destination even for countries which had highly diverse trajectories in the past. Many different histories merge into one master history, many different time scales merge into one master time scale. The imagined time is linear, only allowing for progressing or regressing; and it is global, drawing all communities worldwide into its purview. In contrast to cultures which may embrace a cyclical view of time or which live out stories enshrined in myths, the linear view of time privileges the future over the present, and the present over the past. As the concept of linear global time spreads, indigenous peoples like the Rajasthani in India or the Aymara in Peru, for instance, are compelled to put aside their particular chronographs. They are inevitably pulled into the perspective of progress.

Of course, the belief in progress predates the development age by almost two hundred years. The European Enlightenment was already able to interpret the multiplicity of cultures in space as a succession of stages in time, viewing history as a never-ending process of improvement. Taken from biology, the metaphor development constructed history as a process of maturation; society is likened to, say, a flower which develops according to inner laws, in a continuous and irreversible fashion, towards a final stage of bloom. However, since about 1800,

development has only been used as an intransitive concept (Wieland, 1979); authors such as Hegel, Marx, and Schumpeter conceived it as a process of history's own making, but not yet as a project to be carried out under the direction of human will and reason (Lummis, 1996). This changed with the advent of the development age. Development took on an active meaning; it turned into a project of planners and engineers who set out to systematically remodel societies to accelerate maturation; a project to be completed within several decades, if not years.

Such optimism was facilitated by the fact that economic performance had become the all-encompassing measure of a country's excellence only after 1945. Sir Frederick Lugard, the inspirer of British colonial theory in the 1920s, had still conceived the task of a colonial power as a dual mandate; as both the economic development of colonial territories for the benefit of industrial countries and as moral concern for the native populations (Lugard, 1922). Economic progress and the welfare of the natives had been considered as two distinct duties; the civilizing mission had comprised both developing resources such as land, minerals and timber, and elevating the natives to a higher level of civilization. It was only at the time of Truman that the double mandate collapsed into one: development. The former distinction between an economic and a moral realm vanished, a sign of a conceptual shift. From then on, not only resources figured into the development formula, but people as well. Inversely, the moral concern for people was eclipsed by the economic concern for growth. This shift indicated that a new worldview had come to the fore: the degree of civilization of a country can be measured by its economic performance.

As it happened, this measure of excellence has been available only since 1939, when Colin Clark for the first time compiled national income figures for a series of countries, revealing the gulf in living standards between rich and poor (Arndt, 1987, 35). GNP *per capita* provided a ready-made indicator for assessing the position of countries moving along the road of development. Informed by an economic worldview and aided by a statistical toolkit, experts for decades to come de ned development as growth in output and income per head. A developing country is one with real *per capita* income that is low relative to that in advanced countries like the United States, Japan, and those in Western Europe (Samuelson and Nordhaus, 1985, 812).

Hierarchic Global Space and the Imperative of Catching-up

As already indicated, the chrono-politics of development was, and is, accompanied by a particular geo-politics (Di Meglio, 1997). Through the prism of development, the confusing diversity of nations across the globe appears as a clear ranking order shaping the orientation of both the powerful and the less powerful. After all, the very metaphor of development implies predominance. Just as immature fruit can be only recognized by comparing it to a mature fruit, the stages of underdevelopment can only be recognized by displaying particular societies as examples of maturity. Development without predominance is therefore like a race without direction; assigning the positions of leaders and followers is part and parcel of a developmentalist construction of history.

While inequality between nations in colonial times was understood within an authoritarian framework, which can be likened to a father-child relationship; in the development age it was seen in an economic framework, which can be likened to a race between differently endowed runners. Indeed, staying with that image, it can be said that development policy basically had two objectives: rst, bringing countries onto the racetrack, i.e., into the orbit of the world market; and secondly, turning them into competent runners, i.e., putting them on a path of sustained growth. However, it was only after the diversity of living conditions had been reduced to a hierarchy of aggregate national income gures that the enormous distance separating rich and poor countries leaped into view. No matter what ways of life the Kikuyus in East Africa or the Gujaratis in India cherished, no matter what ideals they aspired to, in the development mindset their diversity is crammed into one single category; they are underdeveloped. Thus, entire peoples found themselves locked into being de cient, de ned not according to what they are and want to be, but according to what they lack and are expected to become.

As is so often the case, the de nition of the problem already implied the solution. When low income is considered the salient problem, raising incomes is the key solution. Any desire for change in Southern countries was thus reinterpreted as demand for economic development, casting aside other possible interpretations: for example, that oppression or dependency might be the problem which would call for liberation or autonomy as a solution. Nor was there a notion that cultures might in the rst place aim for non-economic ideals, be it the integrity of the clan or the celebration of religious rituals. On the contrary, the race in the economic world arena, like any race, was seen to be dominated by the imperative of catching up. Indeed, the chrono-politics and geo-politics particular to the development idea engendered a monumental historical promise: the promise that, at the end of the day, all societies would be capable of bridging the gap to the rich and sharing in the fruits of industrial civilization. It may be in this promise that the foundation of the development creed in Christian thought becomes most palpable (Rist, 1997). Development can be understood as a secular salvation story, constituting an ecumenical community, which places its trust in the good works of providence and faithfully follows the path of predestination (Tenbruck, 1989).

Rising Nation States and the Social Contract

After World War II it was incumbent upon the United States to project a New World Order. Germany and Japan had been defeated; France and Britain seriously wounded. As the colonial powers lost their grip on the world, independence movements sprang up in the South and claimed the right to nation states. A power vacuum opened which threatened to be filled either by violence or communist takeovers. In this situation, the US launched (following its own self-image) self determination, free trade, democracy, and international cooperation as the core values of a future order. A world was presented which is held together by economic interdependence and not any longer by political dominion. Economic strength had taken the place of military power. As colonialism had occupied overseas territories, the doors to political freedom would be thrust open: provided, at least, that trade could flow freely. The US, having itself emerged as a nation from an anti-colonial struggle, readily backed the process of de-colonization, proclaiming at the same time economic development as an overarching goal. Development was thus a conceptual vehicle for American dominance with a liberal face; it allowed for heralding national independence while expanding predominance. A new model of power appeared on the horizon: anti-colonial imperialism.

Decolonization implied the building of numerous nation states in Asia and Africa. As in 19th century Latin America, the nationalist leaders aspired to that model of political organization, which had been forged into a European norm through centuries-long struggles against the Pope, local lords, and foreign intruders. The nation, after all, is an imagined community, residing within the confines of a particular territory and governed by a sovereign state (Anderson, 1983). Establishing the nation as the relevant community (as opposed to family clans or religious affiliations), carving out governable territorial units, and imposing the authority of a bureaucratic state, was an arduous task which called for a mobilizing narrative. The development idea provided legitimation; it became the *raison d'être* for the emerging states. The new governments largely internalized the image thrust upon them by the countries perceived as advanced; they saw in the fight against underdevelopment the mission of their nations. In a certain sense, the right to self-determination had thus been acquired in exchange for the right to self-definition (Rist, 1997, 79).

Moreover, the perspective in which one would eventually catch up with the rich countries restored self-respect and pride to countries, which had been humiliated by colonialism. Such a perspective promised the new countries an equal standing among nations; the demand for development expressed the desire for recognition and justice. What fuelled the determination to catch up was a double asymmetry in power between the South and the North. Culturally, the West had become the intimate enemy (Nandy, 1983) of the indigenous elite, giving shape to their imagination of success; and politically, the might of the North had become so formidable that pure survival instinct forced the South to seek similar economic and technological means. As this asymmetry widened during the decades which followed, the demand for development grew stronger and more desperate up to the point of codifying a right to development in the United Nations General Assembly of 1986. Then and before, the emerging countries reinterpreted the power gap as a development gap. Apart from some exceptions, they saw no other choice than to join the race.

However, the rich nations also had a stake in making development a global project, in whose name a social contract of cooperation could be forged between North and South. After the horrors of war, it was commonly held belief in the UN that peace could only be preserved by launching economic development on a worldwide scale. Virtually all countries rejected at that time the supremacy of the market and believed in the active management and planning of the economy by the state (Hobsbawm, 1994). In particular the US, attributing the outbreak of war in Europe to economic disorder, remembered their own successful management of the crisis during the New Deal, when J M Keynes had recommended state action to counter unemployment and underproduction. Freedom from fear and want had been already held out by President Roosevelt in the Atlantic Charter of 1941; it is from this point that development became a cornerstone of the mission of the UN. For the sake of stability and peace, the need for economic growth (steered along through public intervention) was projected upon the world. In this sense, development can be seen as an exercise in global Keynesianism to keep disorder at bay. Both the hegemonial needs of the North and the emancipatory needs of the South converged upon the prospect of development.

The Poor as Target and the Dethronement of GNP

The situation was rather straightforward in the two post-war decades. Despite differences in approach, development had been identified with economic growth, if not plainly with industrialization. No matter if shortage of physical capital or shortage of human capital was seen as the major deficit, both answers (capital formation or schooling) had aimed at increasing the flow of goods and services. However, the concept of development began to be contested in the 1970s when attention shifted to the poor, exposing the failure of growth to benefit the large majority of people. Robert McNamara, incoming President of the World Bank, put a finger into the wound:

> Growth is not equitably reaching the poor ••• Rapid growth has been accompanied by greater maldistribution of income in many developing countries ••• We should strive to eradicate absolute poverty by the end of the century. That means in practice the elimination of malnutrition and illiteracy, the reduction

> of infant mortality and the rising of life expectancy standards to those of the developed nations.
>
> (McNamara, 1973)

Merely watching the rate of income growth was not enough anymore, the social content of development now mattered. For whose benefit? emerged as the benchmark question. As a consequence, the scope of attention expanded; not only the middle classes boosting market output, but also the populations left out by growth, and even the victims of growth, all became targets for specifically designed interventions. Development was thus redefined as something transcending growth, as economic growth plus redistribution, plus participation, or plus human development. In this vein, throughout the years that followed in quick succession, areas like employment, equality, poverty eradication, basic needs, informal sector, and women were established as fields of development action, each of them bringing a new set of tools and a new tribe of experts to the fore.

With these extensions, a conceptual inflation set in. Soon, development meant everything and nothing, the concept ceased to denote anything in particular, it just connoted good intentions. It had no content, but retained a function: it justified any action in the name of some higher evolutionary goal. However, what the concept lost in semantic precision, it gained in political versatility. Opposing camps both claimed to promote development; the struggle over meaning reflected from now on the struggle over policy. In particular, the controversies turned again and again on the role of economic growth, with a focus on GNP growth lined up against a focus on social or (later) environmental quality. While the first focus cherished the positivism of growth, the latter centered on non-economic wealth. While the first pushed output, the latter cured the consequences. It thus follows that development can be both the injury as well as the therapy.

At any rate, this dichotomy continued to shape the development debate for subsequent decades (Nederveen Pieterse, 1998). A straight line runs from the International Labour Organization (ILO's) world employment strategy in 1970 to the basic needs approach and finally the Human Development Reports of United Nations Development Programme (UNDP) in the 1990s. Similarly, a line can be drawn from the export promotion of the Asian Development Bank in the 1970s to structural adjustment in the 1980s and finally the bailing-out policies of the International Monetary Fund (IMF) in the 1990s. Some growth skeptics have subsequently redefined development as enlarging people's choices and capabilities, a formula which provided the foundation for the Human Development concept with its emphasis on literacy, health and participation. Its essence is to place development at the service of people's well being rather than people at the service of development (Banuri *et al.*, 1994, 16). Even this view, however, (along with more recent creations like the social capital approach) cannot escape the shadow of the development creed; the Human Development Index is, much like the GNP, a deficit index; it ranks countries hierarchically, assuming that there is only one best way of social evolution.

A New International Order and the Rise of Third Worldism

The states, which had emerged out of the crumbling colonial empires, did not stay long without a voice in international affairs. After the Nonaligned Movement had formed at Bandung in 1955 so as to put some clout behind the de-colonization process, the G 77, set up in 1963 at the eve of the first United Nations Conference on Trade and Development (UNCTAD) Conference, aimed at articulating collective bargaining power in the world economic arena. Development ceased to be seen as an objective to be achieved in individual countries, but was thought to require a less hostile international economic structure. Obstacles to development are not just to be found in domestic habits and institutions, as suggested by the modernization discourse; they now present themselves as well in the detrimental terms of international trade. This framing of the development problem was intellectually prepared and further elaborated by the so-called dependency theory , which identified structures of unequal exchange and in general the gradient of economic power as the source of continuing underdevelopment. Responding to their structurally peripheral position, Southern countries, perceiving themselves as sharing the same destiny, formed a coalition demanding a new international economic order. The South opposed itself to the North: a constellation which reached its high-point in the 1970s as the oil exporting countries successfully displayed their collective market power with regard to the affluent economies.

Although the demand for redefined rules in the world economy weakened as the oil cartel collapsed and the debt crisis exploded in the 1980s, the G 77 continued to be a major player in UN politics, in particular after the rise of East-Asian countries as serious competitors. In 1991 the South Commission restated the call for a fair world order (South Commission, 1991). More specifically, the moment the North began to call upon the South for cooperation in environmental matters, the Southern coalition, all internal differences notwithstanding, renewed their grievances about the asymmetry of power. Since then, in environmental negotiations, the claims to greater economic space are bargained against demands for a wiser use of the biosphere. Until today, however, this quest for equal power and recognition remains focussed on relations between states, leaving the question of inequality within countries in the dark. Just as the Declaration on the New International Economic Order of 1974 had failed to mention domestic inequality even once, the calls for greater justice still sounded

hollow in the nineties because the ongoing marginalization of social majorities remained hidden behind the veil of national sovereignty.

Disrupted Nature and the Conservation of Development in Time

In the 1980s, the promise of development received a second blow. While a decade earlier the persistence of poverty had begun to undermine the concept's social viability, now the emerging natural limits to growth cast doubts on its long-term viability. Combustion based on fossil energy, the core of industrial metabolism, threatened to overburden the atmosphere and the growing world economy's voracity for living resources threatened to destabilize forests, water quality and soils across the globe. Against the backdrop of emerging biophysical limits to economic growth, the development idea underwent yet another round of conceptual inflation. Following the logic of turning victims into clients, development had to be reworked to allow for both infinite growth and preservation of nature. Again, a qualifier was attached, defining *sustainable development* as development that meets the needs of the present without compromising the ability of future generations to meet their own needs (World Commission on Environment and Development (WCED), 1987, 8). The formula pointed to the future, but to a bleak future of scarcities rather than a bright future of progress. It called for development choices that would not drastically restrict the environmental space available for future generations.

Although highlighting justice in time, the canonical formula underemphasized justice in social space. Constraints imposed by the present generation on future generations were given prominence over constraints imposed by powerful groups on less powerful groups within one generation. Needs and generations, after all, are socially neutral terms; they do not allow for vertical distinctions. Yet such distinctions are crucial when it comes to intra-generational equity. Whose needs and what needs are supposed to be met? Is sustainable development supposed to meet the needs for water, land and economic security or the needs for air travel and bank deposits? Is it concerned with survival needs or with luxury needs? Leaving these questions up in the air, the acceptance of sustainable development in circles of privilege and power was facilitated, obfuscating the point that there may be no sustainability without restraint on wealth.

Furthermore, by linking *sustainable* to development, a terrain of semantic ambivalence was created. The new concept subtlely shifted the locus of sustainability from nature to development; while sustainable previously had referred to renewable resources, it now referred to development. With that shift, the perceptual paradigm changed. The meaning of sustainability slid from conservation of nature to conservation of development. Given that development had conceptually become an empty shell, which may cover anything from the rate of capital accumulation to the number of latrines, exactly what should be kept sustainable was unclear and contentious. Hence all sorts of political players, even fervent protagonists of economic growth, have in subsequent years been able to couch their intentions in terms of sustainable development. The term had soon become self-referential, as a definition offered by the World Bank neatly confirms: What is sustainable? Sustainable development is development that lasts (World Bank, 1992, 34).

LEGACY

For fifty years, development has been much more than just a socio-economic endeavor; it has been a perception which models reality, a myth which comforts societies, and a fantasy which unleashes passions. However, perceptions, myths, and fantasies rise and fall independent of empirical results and rational conclusions. They rise when they are pregnant with promises, and they fade when they turn into sterile commonplaces. Achievements such as the average rise of *per capita* GNP in Southern countries from 1960 to 1997 at a rate of 2.1% per year, the success story of a number of East-Asian economies, or the declining rates of infant mortality even in the group of low-income countries, are not indicative enough to fortify the faith in development. In the same way, the enumeration of failures, such as the rising absolute number of poor people (living on less than $1 per day) worldwide, and their slowly increasing relative number in Sub-Saharan Africa as well as in Latin America, is not necessarily forceful enough to undo that faith. Instead, a world-view, like development, loses appeal when the implicit promises cease to command credibility. This is what has happened in the last 10–15 years; the three founding promises: that economic development will spread across global space, improve human destiny, and continue for ever in time, have turned stale.

Social Polarization

After fifty years of development, the promise of greater justice in the world has largely evaporated. In the international arena, the notorious gap in income between North and South has not been bridged; on the contrary it has widened to an extent that it is now unimaginable that it could ever be closed. In 1996, the 20% of the world population living in affluent countries had an income at their disposal 82 times higher than the poorest 20% of the world population; in 1960, it was just 30 times higher (UNDP, 1998, 29). Upon closer inspection, to be sure, the picture is far from homogeneous because these relative figures hide, for instance, that *per capita* income in oil-exporting and in East Asian countries has sharply risen during the last 20 years.

But absolute impoverishment proceeds at the same time; *per capita* income in more than 80 countries is today lower than it was 10 or more years ago (UNDP, 1999, 3). Social polarization among countries advances, while the size and the composition of the poles may change. The world might have developed, indeed: but in two opposite directions. Looking at the over-all picture, it is probably no exaggeration to say that the aspiration of catching up with the rich has ended in a blunder of planetary proportions.

This is even more true if one considers the destiny of large majorities of people within most countries; the polarization between nations (often, but notably not in India and a number of East Asian countries) repeats itself within each country. In Brazil, for example, the share of the poorest 50% of the population in national income amounted to 18% in 1960, while it fell to 11.6% by 1995 (UNDP, 1998, 29). Economic growth, it turns out, has often failed to reach its most heroic objective; to alleviate the burden of the poor. Investments in ports, roads, steel mills and fertilizer plants might have fuelled national income, but they have rarely trickled down to the poor. In fact, it has taken decades of misplaced development assistance to discover that there is only a loose relationship between levels of economic growth and levels of poverty. Growth, it turns out, is certainly not sufficient for mitigating poverty; land rights, community coherence, and self-organization have been shown to be at least as important. Yet, precisely these conditions of livelihood have often been undermined in the pursuit of growth. Dams displace people, machines substitute rural workers, cash crops replace subsistence crops, urban migration follows the loss of self-affirmation. More often than not, the natural and social base of livelihood economies have thus been exploited for building the base of a market economy. Against this backdrop, it is not astonishing that the spread of misery has often accompanied economic growth.

The development perception, having for a long time seen poverty as simply a lack in income, failed to appreciate life-enhancing, non-market resources for the poor, such as rights, social capital, and natural resources. As a consequence, the application of growth recipes had a polarizing effect; it turned frugality into misery, making a minority better off in the process. Moreover, in staying true to its bias that only income growth matters, the development perception remained blind to the effect of unequal power relations. However, as access to money and non-money resources is determined by power, growth without redistribution of power enabled the urban middle classes, manufacturers, and big farmers to corner the gains of prosperity, shifting the cost to small farmers, indigenous people, and the urban proletariat. And still today, a totally disproportionate share of economic gains in Southern countries goes to the rich and politically well connected (Ayres, 1998, 126). Through development, furthermore, countless people have been drawn into the money economy, a transition which modernized both poverty and wealth (Illich, 1971). Where the gradient of power and prestige is calibrated according to purchasing power, expectations tend to explode while opportunities remain limited. Given that satisfaction is relative to expectations, fuller integration into the money economy may therefore even increase the feeling of poverty. Television sets in shacks have become symbols for the unbridgeable gulf between means and expectations.

Unsettling of Cultures

The most dramatic and far-reaching social change of the second half of the 20th century, the one which separates the modern world forever from the past, is the death of the peasantry (Hobsbawm, 1994, 289). This marked the end of several thousand years of cultural evolution when the overwhelming majority of the human race lived by agriculture, raising livestock or harvesting the sea as fishers. After the peasants of rural Europe and Japan had more or less stopped tilling the land by the 1960s, Latin America, large tracts of Asia, and North Africa followed suit in the last decades of that century. Only three regions of the globe remained essentially dominated by their villages and fields: Sub-Saharan Africa, South and continental South East Asia, and China. However, while in the Northern countries the population of the shrinking agrarian world was largely absorbed by the expanding industrial world, in the Southern countries only a minority in this transition found a dignified living in towns and cities. Nevertheless, urbanization has continued to change the human condition on an ever more massive scale. Just during the last 25 years, the share of the world population which is living in urban areas went from slightly more than one third to one half, a figure which is expected to rise to two thirds by 2025 (World Bank, 2000, 46). Development policy, indeed, had set out to propel agrarian societies into the urban-industrial age. It sought to replace traditional Man by modern Man, an endeavor which, however, ended in fatal success; while traditional Man has vanished, modern Man has by no means arrived. Living in a no-man's land, exiled from tradition and excluded from modernity, has become the destiny of most of the world's people.

Nothing less than turning entire societies upside down has been the intent of development planners right from the start. For example, the 14-person mission to Colombia, the first of its kind sent out by the Bank for Reconstruction and Development (later the World Bank) in 1949 arrived at the following conclusion:

> Piecemeal and sporadic efforts are apt to make little impression on the general picture. Only through a generalized attack throughout the whole economy on education, health, housing, food, and productivity can the vicious circle of poverty ••• be

> decisively broken. But once the break is made, the process of economic development can become self-generating.
>
> (Escobar, 1995, 24)

In this engineering spirit, experts set out to remake societies from a host of locally based subsistence communities into nationally integrated economies. They aimed at reorganizing social ties in functional terms, as called for by the ambition to set up machinery geared towards producing growing amounts of material wealth. Under the expert s gaze, time-honored ways of living and knowing faded into oblivion, reduced to obstacles to development . Instead, decontextualized production models, depicting people and nature as abstract objects to be changed, were projected upon in nitely diverse human realities. People rarely g-ured as agents in the framework of rationalist planning (Hobart, 1993); their interests, passions, and knowledge hardly mattered against the backdrop of grand schemes for resource mobilization. Small wonder that development strategies based on such models failed time and again; they were too much in dissonance with the dynamics of a given community. It is for this reason that development has always produced both order and chaos.

At any rate, development has often failed to grasp the rich complexity of non-economized societies. It could not appreciate, for instance, that such settings can be regarded as symbolic sites (Zaoual in Rahnema, 1997; Apffel and Marglin, 1998) where communities live out narratives that link them to their divinities or where social energy is primarily invested in the upkeep of a network of friends, relatives or clan members. In such circumstances, any modernization will run quickly into communitarian constraints, as relations to divinities or to fellow citizens are likely to collide with the requirements of functional performance. To put it in more general terms, development has aimed at achieving that decisive shift which distinguishes modern civilization from all others: primacy is not given any longer to the relations between people, but to the relations between people and things (Dumont, 1977). In the rst case, events are evaluated in the light of their signi cance with regard to neighbors, relatives, ancestors, and gods: whereas in the second, they are judged according to what they contribute to the acquisition and ownership of things. This impersonality postulate (Banuri in Apffel and Marglin, 1990) according to which impersonal relations are inherently superior to personal relations can well be regarded as speci cally Western; to make it prevail is what development as modernization was all about.

It is probably true that this shift has been a mixed blessing for large majorities of the world s people. On the one hand, it moved many regions and classes into the modern world with its liberties and conveniences; on the other, it disembedded countless persons from their cultures, sending them to join the global majority of underconsumers. As long as cultures (both large and small ones) are con ned to themselves, people everywhere have tended to view the corner of the world they inhabit as particularly favored and their own ways of life as good: that is, quintessentially human (Tuan, 1986, 1). However, as all cultures are drawn into the maelstrom of global interaction and assimilation, reinforced by the transborder ow of images, this self-con dence can hardly be maintained. As borders limited the space of comparison, they facilitated limited, but attainable satisfaction, while a borderless world, making the space of comparison explode, offers unlimited, but often unattainable satisfaction. This goes a long way in explaining why both excitement and dissatisfaction grow along with globalization.

Nature's Predicament

After the Second World War, the US, along with other industrialized nations, could still feel it was at the forefront of social evolution. After 50 years this premise of superiority has been fully shaken (if not shattered) by the ecological predicament. Using the racetrack metaphor, development may have been a race, which was conducted unfairly, and which has driven the majority of runners to exhaustion, but its demise is imminent before the tribunal of history because the horses appear to be running in the wrong direction. From the local to the global level, many experiences have shown that the sources (water, timber, oil, minerals etc.), sites (land for mines, settlements, infrastructure), and sinks (soils, oceans, atmosphere) for the natural inputs of economic growth have become scarce or have been thrown into turbulence. As a consequence, the promise that development will continue for ever has collapsed. For instance, if all countries followed the industrial example of emitting *per capita* on average 11.4 tones of CO_2 annually, the emissions of six billion people would amount to roughly 68.4 billion tones; more than ve times the 13 billion tones the earth is capable of absorbing. In other words, to bring all countries up to the present standard of living in af uent countries, ve planets would be needed to serve as source for the inputs and sinks of economic progress. Against this backdrop, development has moved into an impasse. With biophysical limits to economic expansion (hard to pin down and ever contestable, but nevertheless real) emerging in the last quarter of the 20th century, the North cannot be held up as a model any longer; the trail-blazers are without a compass. The recognition of the niteness of the earth has been a fatal blow to the idea of development as envisaged by Truman.

In fact, ecological constraints represent only half the story; they are compounded by the fact that approximately 20% of the world population consume 80% of the world s resources. The majority of the global consumer class roughly those that have a bank account, some career prospects, and access to a car can be found in the North.

It is those 20% who eat 45% of all meat and fish, consume 68% of all electricity, 84% of all paper, and own 87% of all cars (UNDP, 1998, 2). They can be called the omnivores (Gadgil and Guha, 1995), namely those who are capable of cornering environmental resources to their benefit at the cost of other groups. In the global context, the industrialized countries tap into the patrimony of nature to an excessive extent; they draw on the environment far beyond their national boundaries. The ecological footprint (Wackernagel and Rees, 1996) (*see* **Ecological Footprint**, Volume 3) that they produce is larger (and in some cases much larger) than their own territories; a great deal of the resources and sinks they utilize are not available for other countries anymore. In fact, the Organisation for Economic Cooperation and Development (OECD) countries surpass the (in terms of ecology and equity) admissible average size of such a footprint by a magnitude of about 75–85%; as matters stand today, the wealthy 25% of humanity occupy a footprint as large as the entire biologically productive surface area of the earth. In a closed environmental space, the question of how much is tolerable therefore becomes intermingled with the question, who is getting how much?

But also within countries, in particular Southern nations, the consumer classes often succeed in sequestering themselves against environmental burdens, leaving the noise, the dirt, and the ugliness of the industrial hinterland at the doorsteps of less advantaged groups. In 1994 13% of Southern urban citizens lacked access to clean drinking water, and almost twice as many did not even have the simplest latrines (World Bank, 2000, 140). Contrary to the *fata morgana* of development, health conditions for the poor in cities are today worse than in rural areas. Moreover, just as in the case of the citizens of the industrial world, the Southern middle classes live off the resource base which supports the ecosystem people (Gadgil and Guha, 1995), that third of the world population (UNDP, 1998, 80) which derives their livelihood directly from free access to land, water, and forests. Building large dams and extracting ore, drilling groundwater wells and capitalizing agriculture for the benefit of the urban classes often degrades the ecosystems on which they depend. As the appropriation of resources can often only proceed after the rights of inhabitants have been denied, human rights violations frequently go hand in hand with resource conflicts (Johnstone, 1994). Such kinds of pressures, adding to others like unequal landholdings or a growing population, may turn ecosystem people into landless and rootless squatters who have no other choice than exhausting fragile lands and woods. It is only a slight exaggeration to say that development in these cases deprives the poor of their resources in order that the rich may live beyond their means.

In sum, environmental degradation arises from two contradictory settings: one of success and domination, the other of marginality and powerlessness. In the first instance, corporations and consumers of the affluent world dispose of the economic power to mobilize, if necessary over long distances, huge amounts of resources, producing pollution, devastation, and turbulence in the process. In the second instance, poor people without purchasing power degrade their habitats, after having lost their traditional rights or any other kind of entitlement to secure sufficient sources of livelihood. Both the degradation by the affluent and the degradation by the poor can be largely considered the outcome of one and the same process of economic development. Resource voracity on the part of the powerful, and resource scarcity on the part of the powerless, combine in pushing the planet to the brink.

TRANSITION

It is not just its own fading promises, but also shifts in the world economy that have contributed to the decline of the development age. Since the mid-1980s the accelerated rise of globalized markets along with the arrival of an information-based economy has profoundly changed the post-war international order, a transformation which played itself out fully the moment that the East–West division of the world collapsed in 1990. In essence, studies on development had concentrated on the transition of nation states from agrarian to industrial. With globalization, the coordinates of modernization have changed; the agenda is now dominated by the shift of power from nation states to transnational markets and from industrial structures to informational structures. Deterritorialization and dematerialization (*see* **Dematerialization of the Economy**, Volume 4) have emerged as powerful trends, which escape the categories of development, without however, canceling the aspirations behind it. For the hopes which nourished the development creed are more alive than ever – the hope of the poor for a life in dignity as well as the hope on the part of Southern elite to be finally on an equal footing with the affluent North.

Globalization Instead of Development

In the course of globalization, what can be called the Westphalian constellation (Menzel, 1998) is reaching its end. For it was after the Peace of Westphalia in 1648, which established the principle of territorially bounded sovereignty that a particular form of polity, the European nation-state, came into existence. In its idealized version, the nation-state circumscribed a territory upon which a polity, an economy, a nation, and a culture rose. Like a container, it was supposed to hold society in all its layers within a demarcated space, creating a self-enclosed entity which in turn engaged with other such entities on the international level (Beck, 1997). Though reality never conformed to this

conception entirely, these containers finally burst open with globalization. Goods, money, information, images, people flow across borders, giving rise to a transnational social space where interactions occur over long distances, sometimes even in real time. As a consequence, the former (though always partial) integration of economy, polity, and culture within a territory breaks apart, turning states into just one player amidst transnational networks of exchanges in many spheres of life.

Against the background of these changes, development loses both its object and its agent. As a matter of course, the development discourse had focussed on the transformation of territorially bounded societies; they were thought to be the units by which social evolution proceeds. States were thus the privileged sites of development. However, as societies are perforated by transborder flows (be it through foreign capital, satellite television or migrants), the objective of development planning begins to dissolve. Attention no longer focuses on developing national economies, but either on inserting certain players successfully into the world market or on securing livelihoods for local communities. Likewise, the agents of development change. While previously the state was expected to be the engine of development, several new agents, all of them moving largely irrespective of borders, now diminish the role of the state. In this vein, private foreign investment has overtaken public assistance, television imagery has superseded national narratives, and non-governmental organizations (NGOs) have shouldered many development projects. At the present time, the development concept looks strangely out of place in the era of globalization.

Furthermore, the development creed had been embedded in a conception of linear worldwide progress, which fails to resonate with a globalist mindset. During the heyday of industrial modernity, history had been conceived as a movement with a direction, a universal process whose pointer was called rationalization or liberation (Bauman, 1992). This predominance of time over space in ordering worldviews, however, has been turned around by the shift in consciousness, which is connected with globalization. For what captures the attention of the post-modern mind is not a clear universal sequence of social change, but the simultaneous presence of a plurality of differences across geographical or virtual space. In perception, space gradually gains the upper hand over time; it is not the sequence of things that matters, but their possible combinations. The present change in guiding metaphors can be taken as an illustration; the road of progress is being replaced by the connectivity of networks. While the former saw societies as progressing along a time scale, the latter sees shifting patterns of flows between non-contiguous locations. In the transnational and digital world where success depends on being inserted into relevant, ever shifting circuits and not primarily on the position of one's country on the racetrack, the development idea ceases to express the excitement of the day.

The New Divide

Among other things, *globalization* tends to undercut social solidarity, both nationally and internationally. As societies are less and less contained within nation states, the reciprocal links between social classes, which constitute a polity, become weakened. After all, the nation state, in particular as long as social Keynesianism had been on the agenda, was capable of rebalancing the relations between the rich and the poor, be it as welfare state in the North or as developmentalist state in the South. Under the pull of the transnational economy, however, the social contract which lay at the core of the redistributive state has begun to unravel. As the elites aspire to catch up with the vanguards of the international consumer class, their old-style sense of responsibility for the disadvantaged sections of their own society withers away, because they themselves, instead of feeling superior with respect to their countrymen, feel now to be inferior with respect to their global reference groups. Following this drift, governments are inclined to ally themselves with the globalizing forces and increasingly show disregard for the majority of their citizens who live outside the global circuit (Kothari, 1993). Committed to promoting the insertion of their industries and middle classes into global markets, they consider the non-competitive social majority a liability rather than a boon. As a result, in many societies a split opens up between the globally oriented middle class on the one side and (in terms of the world market) superfluous populations on the other. While globalization removes barriers between nations, it thus erects new barriers within nations.

Equally, the social contract between rich and poor nations, which, all counter forces notwithstanding, had laid the base for international development policy after the Second World War, did not survive the onslaught of transnational competition. Neither within nor between states is there much concern any longer for redistribution. Already in the 1980s the politics of structural adjustment largely replaced the development consensus, giving priority to macroeconomic stability in favor of an unhampered transborder mobility of capital. Deregulation and liberalization were supposed to bring indebted countries up to the standard of a free-trade player: yet in many cases the less advantaged sections were just brought to their knees. Disregarding social and environmental costs, currency stability became the entrance ticket to the circuit of transnational capital flows, and thus became the overriding objective of the IMF and the World Bank. This implied a shift of focus; the concern of dominating development agencies was now creating a stable playing field for transnational corporations and was no longer interested in improving the welfare of

the people. However, the process by which development institutions could become agents of the world market rather than agents of societal welfare was facilitated by the success of about ten emerging markets in export-led growth. Along with the former rise of oil producing economies and the dissolution of the Eastern Block, this success finally split the Third World as a somewhat homogenous group of nations. South Korea, for example, which in 1960 had still been on a par with Bangladesh, produced in 1996 as much output as the entire Sub-Saharan African region. Globalization, in other words, made a number of Southern economies (or regions therein) into players on the world market, at the price, however, of driving a deeper wedge between them and the large majority of countries in the South.

The more that shifting transnational space encompasses not entire countries, but only larger or smaller sections of a country, the more obsolete the North–South division becomes. Indeed, the dividing line, if there is any, in the world of globalization does not primarily run between Northern and Southern countries, but the line separates the global middle class on the one side and the excluded social majority on the other. The global middle class is made up of the majority in the North and a smaller elite in the South; its size equals roughly that 20% of the world population which has access to an automobile. Globalization accelerates and intensifies the integration of this class into the worldwide circuit of goods, communication and travel. But an invisible border separates in all nations, in the North as well as in the South, the rich from the poor. Entire categories of people in the North, like the unemployed, the elderly and the competitively weak, just as entire regions in the South, like rural areas, tribal zones and urban settlements, find themselves excluded from the circuits of the world economy. Even information-based capitalism, by linking valuable players and places in a non-contiguous pattern, turns people and territories across countries into black holes of informationalism (Castells 1998, 161). At any rate, the major rift today appears to be between the globalized rich and the localized poor; the North–South divide, instead of separating nations, runs through each society, albeit in different configurations.

Security Instead of Development

As the development consensus faded away, two themes have emerged in its wake. The first is globalization and is concerned with the stability of the transnational economy. Its aim is the expansion of global markets leading to greater welfare. The so-called Washington Consensus of 1986, which declared structural adjustment to be the highest form of development, can be considered its take-off point, and the IMF its guardian. The second theme cherishes security and is concerned with protection against risks. Its aim is the need for prevention in the face of threats to human survival and dignity. UNDP's Human Development Report, which annually explores the state of human security, may exemplify this current, although the debate on *environmental security* (Mathews, 1989) is part of this mode of thought as well. To some extent, the two themes are merely a reincarnation of the 1970s conflict between top-down, pro-growth on the one side, and bottom-up, pro-poor approaches on the other.

The concern for security crystallized in the 1990s after the promises of development had lost credibility. With the high-flying optimism that once powered development withering away, the perceptions changed; the South ceased to be seen as young and full of potential, as in the time of Truman, but as the breeding ground of social and environmental turbulence. In particular, no one still clung to the ideal of a radiant future for the social majority, which has become superfluous in terms of the global economy. The best that could be achieved is survival in decency. Moreover, as globalization not only provides comforts, but many woes as well, the North felt increasingly threatened by immigration, civil wars, and environmental competition. As a consequence, the South is no longer considered with hope, but with suspicion; developing countries turn into risk zones, and their less advantaged citizens are primarily perceived as risk factors. Development policy shed its skin again. It has now largely adopted a security agenda where prevention replaces progress as the objective of development. Catching up is out of the question, assistance now aims at preventing the worst scenario from happening. Securing people's livelihood is the noble concern, projects for clean water, market access, woodless stoves, or community organization, are typical examples: a far cry indeed from reaching a modern paradise. But also the notion of security is a contested terrain; the question looms large: whose security – that of vulnerable people or the security of the OECD-dominated economy? While, for instance, many NGO's work to enable the less advantaged to protect themselves, on the diplomatic level the stakes are often different. International negotiations (in particular environmental negotiations), in a world risk society, deal implicitly with the defense of the stronger against the risk presented by the weaker. The redistribution of risks and not any longer the redistribution of economic opportunities is their hidden agenda. For both grassroots movements and governments, security has thus become a key concern because this is all that is left of the development idea after the belief in progress has vanished (*see* Environmental Security, Volume 5).

PROSPECTS

The development age might have withered away, but its core agenda is still unfinished. For decades, development

had provided language for voicing the desire for justice. Yet justice in both its basic forms, as redistribution of opportunities and as recognition of otherness, fails to have made much progress, at least beyond the confines of the global middle class. However, the agenda is not only unfinished, it also faces new constraints. For the meaning of justice is bound to change in an era of biophysical limits. As long as limits were not on the horizon, justice could be identified with growth. The famous metaphor of the growing cake which eventually offers larger pieces for everyone without imposing smaller pieces on anybody illustrates how the idea of open-ended growth could nicely sidestep hard questions on equity. But in a closed environmental space, the claim for justice cannot be reconciled any longer with the promise of material intensive growth, at least not for the world's majority. For this reason, the quest for justice will need to be decoupled from the pursuit of development with a capital D.

Contraction and Convergence

Under conditions of finitude, there is only a limited part of the global environmental space available for each country. Therefore, the concept of development as a racetrack without a finishing line is historically outdated. In order to envisage sustainability scenarios for this century, in particular in the context of climate change, it is helpful to distinguish two distinct trajectories beginning from two opposite poles and spanning a variety of initial conditions. Northern countries start their trajectory towards a low-risk and equitable level of fossil energy flows from high consumption levels, reducing them over time until they reach levels sustainable in terms of both ecology and equity. This may be called the *trajectory of contraction*. Southern countries, on the other hand, start from relatively low levels of fossil energy flows, increasing them over time until they approach the trajectory of industrial countries at sustainable levels of resource throughput. This may be called the *trajectory of convergence*. Both trajectories pose related, but different, challenges. For industrial countries, the challenge consists in bringing down resource flows without a decline in human well-being and in social justice. For Southern countries, however, the challenge consists in raising levels of resource consumption at a much smaller gradient than industrial countries did historically; increasing human well-being concurrently with equity.

A similar logic applies to inequalities within countries. Given that the omnivores are not confined to the North, retreating from excessively occupied environmental space will be expected from Southern middle classes as well. After all, the elite in countries like Mexico, China, and Brazil rival the population of many OECD countries in numbers. Therefore, the trajectories of contraction and convergence also apply to the development paths of different social classes.

Towards Resource-light Economies

The models of wealth brought about by the spectacular growth in the OECD countries in the last fifty years are structurally oligarchic; they cannot be generalised across the world without putting everyone's life chances in jeopardy. Chemical agriculture, the automobile society or meat-based nutrition are all cases in point. For this reason, the move towards models of frugal use of wealth among the affluent is a matter of equity not just of ecology. However, conventional development thinking implicitly defines equity as a problem of the poor. But designing strategies for the poor, developmentalists worked towards lifting the bottom, rather than lowering the top (Goodland and Daly, 1993). The wealthy and their way of producing and consuming weren't under scrutiny, and the burden of change was solely heaped upon the poor. In future, however, justice will be much more about changing the lifestyles of the rich than about changing those of the poor.

In order to move towards resource-light economies, two broad strategies can be distinguished. The first is the attempt to gradually decouple economic output from resource flows. For instance, enhancing the ecological efficiency of technologies and organisational structures, aims at reducing the volume of resource input per unit of economic output. In all likelihood, the efficiency of resource use can be enormously increased; examples for eco-intelligent production and services abound (*see* Dematerialization and Sustainable Development, Volume 4). The second strategy is the attempt to decouple quality of life from economic output. Indeed, quality of life has many sources beyond purchasing power; it derives from non-monetary assets as well, such as access to nature, participation in community, or the wealth in public goods. What is at stake here is not the efficiency, but the sufficiency in resource use. Such an orientation aims at the art of sustaining higher qualities of life out of a given set of material inputs; it ponders how much is needed for attaining welfare, value, beauty, and meaning. In brief, the transition to resource-light economies is likely to require a dual-track strategy: a reinvention of means (efficiency) as well as a prudent moderation of ends (sufficiency). In other words, it is about doing things right and about doing the right things.

Leapfrogging into the Post-fossil Age

For Southern economies the challenge is to embark upon growth patterns that are both pro-environment and pro-poor, without going through all the stages of industrial evolution as Northern countries did. At the present moment when the fossil-fuel age is on the decline, economies that once were said to be lagging find themselves in a favourable position. Not yet being locked into old-style industrialisation, they have the prospect of *leapfrogging* into a post-fossil

age, skipping the resource intensive styles of production and consumption of the industrial world (*see* **Leapfrogging Technology**, Volume 4). For instance, Southern countries face important decisions about introducing and designing infrastructures such as energy, transport, sewage, and communication systems, the introduction and maintenance of which in industrial countries have caused the earth s resources to dwindle. Today, many Southern countries are still in a position to avoid this unsustainable course, opting without further detours for infrastructures which would allow them to embark upon a low emission and resource-light trajectory. Investment in infrastructure such as ef - cient rail systems, decentralized energy production, public transport, grey-water sewage, surface irrigation, regionalized food systems, dense urban settlement clusters etc., could set a country on the road towards cleaner, less costly, more equitable, and less emission intensive development patterns. It goes without saying, however, that such a choice is in the rst place not a technical, but a cultural one; it requires envisaging models of wealth different from those in the North.

DEMOCRACY AND ECOLOGY

Environmental resources are valued as a source of livelihood, by groups as diverse as the shermen of Kerala, the forest dwellers of the Amazon, the herders of Tanzania, and the peasants of Mexico. Over the centuries many of these communities had developed complex and ingenious systems of institutions and rules regulating ownership and use of natural resources in such a way that an equilibrium between resource extraction and resource preservation could be achieved (*see* **Indigenous Knowledge, Peoples and Sustainable Practice**, Volume 5). However, particularly under the pressure of the resource needs brought forth by the omnivores, their basis of livelihood has been undermined, degrading their dignity and sending many of them into misery. In such a context, sustainability in the rst place means ensuring the rights of communities both to their resources and to their culture.

Democratic rights and resource productivity are particularly intertwined when it comes to ecosystem people. For their livelihood such communities need to undertake efforts to increase the productivity of all components of the village ecosystem; from grazing and forest lands to croplands, water systems and animals (Agarwal and Narain, 1989). After all, they often suffer from a shortage of biomass rather than from a shortage of cash. However, only conferring a substantial degree of control over their resource base to communities will ensure the degree of power and participation necessary for cultivating forests, elds and waters according to local rules and customs. Democratic rights and entitlement to resources are thus prerequisites for building a biomass-based, non-carbon economy. Ensuring sustainable livelihoods (the ability of an individual or a family to meet their basic needs in a manner that is digni ed, but does not undermine the natural resource base on a large scale) will therefore largely require policies which put democracy, equity, and environmental care before the quixotic pursuit of monetary economic growth.

Anthropology and Global Environmental Change

John H Bodley
Washington State University, Pullman College, WA, USA

The most striking general conclusion to be drawn from the cultural ecological data in the anthropological record is that the speed and scale of resource depletion and environmental degradation accelerates with increases in the scale of culture and the concentration of social power (Bodley, 1994; 2000; 2001). It is signi cant that people living in small-scale cultures were better able to maintain long-term, relatively resilient relationships with the natural environment than peoples living in larger scale cultures. Cultural resiliency is a key feature of successful long-term human adaptability. It is the cultural ability to minimize human-caused detrimental impacts to the environment, while smoothing out the human impact of natural environmental uctuations. Cultural resiliency also means minimizing destabilizing uctuations in human population and human demands on the natural environment. The concept of resiliency is more than that of balance or equilibrium, because it emphasizes the dynamic aspects of human and natural system. These conclusions are contrary to long established beliefs about evolutionary progress, and they challenge the popular ideology that unlimited growth, especially economic growth, is a natural process, and the best way to improve human well-being.

Anthropologists have always been concerned with the relationship between the people they studied and the natural environment. Since the late nineteenth century, the first professional anthropologists focused their research on tribal peoples who were directly dependent on natural resources for their survival. The environment was obviously too important to be ignored. Initially, anthropologists studied how people exploited the environment, then they asked how culture might in turn be shaped by the environment, or by the nature of the human–environment relationship. Nineteenth century anthropologists were often natural historians, and it was common then, and still today, for them to be very broadly interdisciplinary, with interest, and sometimes formal training, in geography, geology, zoology, and botany. During the first half of the twentieth century the anthropological interest in environmental issues led to the identification of cultural ecology as a distinctive sub-discipline. Contemporary prehistoric archaeologists often maintain a focus on environmental issues.

Most early academic anthropologists rejected any simple environmental determinism, but they grouped similar cultures into large culture areas that often reflected underlying

common cultural adaptations to generalized natural areas. Before 1950, pioneer cultural ecologist Julian Steward, cautiously observed that over time people tended to organize themselves in similar ways to exploit similar environments, thus producing broadly similar cultural types in widely separate areas of the world. By the late 1960s, cultural ecologists began to apply equilibrium models to small-scale cultures, treating them as human systems in balanced, adaptive relations with natural ecosystems. These functionalist approaches were largely abandoned because they could not explain how systems developed and changed, and they often treated cultures as artificially closed systems. Since the 1980s, cultural ecologists have increasingly situated the peoples they study within the national and international political economy, and interest has shifted to approaches that will help local peoples defend their resources and subsistence economies. Many contemporary anthropologists continue an environmental focus, but it has broadened to include contemporary commercially organized, and global scale cultures, as well as existing indigenous peoples with small-scale societies.

CULTURAL EVOLUTION AND HUMAN ADAPTABILITY

One of the longest-running theoretical debates in anthropology concerns the nature of cultural evolution. The orthodox view as originally developed by Morgan (1877), and refined by White (1949, 1959) and others (Sahlins and Service, 1960), was that general cultural evolutionary progress was an inevitable and beneficial process of growth and development leading stage by stage to more complex societies, using more energy more efficiently, and with greater adaptability and security. Cultural evolutionists thought that evolutionary progress was such a self-evident human benefit that they did not demonstrate it. White (1949) emphatically declared that culture evolved as the amount of energy harnessed per capita per year increased. The assumption was that cultural evolution gave people greater control over nature, and this was good for people. However, it is significant that the most enthusiastic anthropological exponents of these measures of cultural progress wrote before the energy shortages of the 1970s, and before the United Nations Brundtland Commission (WCED, 1987) report on sustainable development. Thoughtful reconsideration of all the standard measures of cultural evolutionary progress suggests that it must be a maladaptive process.

Leslie White attributed the most recent step in cultural development to the switch to fossil fuels and nuclear energy, but it is now obvious that the advantages of this may prove illusory. Cultures can be arranged in a progressive general evolutionary sequence of increased energy use running from 5000 to 12 000 kcal per capita per day in small-scale band and village societies, 26 000 kcal in pre-capitalist agrarian civilizations, and 230 000 kcal consumed by Americans in the 1970s (Cook, 1971). However, critics pointed out that this sequence does not account for the eventual depletion of fossil fuels, the serious deficits in using non-renewable energy to produce food energy, or the costs of the waste by-products of energy production and consumption. Hubert (1969) predicted that global petroleum production would peak in 1995, and that the supply would be virtually exhausted by 2075. The most telling criticism was the calculation that if energy consumption increased at 5% a year for 200 years, the waste heat produced would equal the heat of incoming solar radiation and the earth would burn up. Fortunately, before such a *Sun Day* the polar ice caps would melt and rising sea levels would flood out most of the power plants (Luten, 1974). Human reproductive success would also be an unattractive measure of human evolutionary progress. If the production of larger, more complex cultural systems is the measure of evolutionary success, then the process still seems maladaptive for long-term human survival, because fewer, larger, more homogenous, and less durable cultures have replaced more numerous, more diverse, and more durable small cultures. Greater cultural complexity creates a human survival problem in part because larger, more complex cultural systems incorporate and subordinate smaller systems.

Some of the evolutionary theorists recognized that small-scale cultures might actually be better adapted to particular local ecosystems than large-scale cultures. White (1949) observed that foragers, with the simplest cultures, may have had the most satisfying kind of social environment that man has ever lived in. Sahlins (1968) noted that foragers were successful because they limited their wants to the consumption levels that their environment and technology could support and they lived satisfying and affluent lives. As the contemporary environmental crisis began to unfold, many anthropologists commented on the connections between self-sufficient small-scale societies and greater social equality, and relative equilibrium with the environment (Bodley, 1975). This suggested the possibility that increased social scale caused inequality, poverty, and global environmental change.

More recent biocultural evolutionary theory shows how cultural evolution could become a maladaptive process that would undermine the resiliency of both natural and human systems. From the biocultural perspective, cultural evolution is produced by changes in culture, which is conceived from the ideas that human behavior is directed in the same way that genes create biological organisms. Cultures change as shared symbolic information changes. The important difference between genes and culture is that individuals intentionally produce and transmit culture, and they can borrow from many sources (Boyd and Richerson, 1987). However, the scale of culture influences how it is created and transmitted. Cultural transmission is frequently

biased, because people emulate the beliefs and behavior that appear to be most successful. Cultural emulation is easy and efficient, but it can lead to maladaptive runaway economic growth and power aggrandizement, which in turn cause global environmental change.

In small, domestically organized societies the members of each household are daily making cultural decisions about technology, production, and consumption. In larger scale, politically organized societies, cultural evolution becomes a political process in which a single ruler can direct the actions of thousands, or even millions of people (Durham, 1991). Household-level decision making is inherently more responsive to local social and environmental conditions, but it can be over-ridden by political rulers who may be far removed from the environmental consequences of their decisions (Rappaport, 1977a,b). Thus, it is not surprising that large scale agrarian civilizations directed by political elites, frequently collapse because they exhaust the resource base, generate social conflict, or become too costly to maintain.

THE UNIQUENESS OF THE CONTEMPORARY ENVIRONMENTAL CRISIS

Bennett (1976) describes a seemingly inevitable ecological transition from environmental equilibrium to disequilibrium. From this viewpoint there is nothing particularly unique about global environmental change. Bennett placed small-scale, tribal societies at the equilibrium end of the continuum, but argued that all people had the same behavioral propensities that would lead to drastic environmental change. However, this mixes human means, ends, and secondary consequences. Biocultural theory maintains that all people are driven by a human nature that seeks domestic security and the future welfare of one's children. Small-scale societies achieve these human ends cooperatively by remaining small, consuming resources sustainably, and resisting aggrandizing individuals who would promote security-reducing growth in consumption. Some people in commercially organized cultures competitively elevate their consumption levels in order to obtain these same ends for themselves. Bennett argues that equilibrium cultures are only pauses in the overall historical tendency toward exponential increases in environmental use and impact. However, historical tendencies are not inevitable; they are the outcome of particular events and individual decision-making.

By the 1980s, as global economic growth and environmental problems intensified, some anthropologists began to argue that people have never been in equilibrium with the environment. For example, Rambo (1985) called Malaysian shifting cultivators primitive polluters, because they put carbon dioxide into the atmosphere and lived in smoke-filled houses. He declared that primitive and civilized societies interacted with the environment in essentially the same way. In a similar vein, Krech (1999) maintains that Native Americans were not always conservationists, and were in the process of exterminating the bison before Europeans arrived. These revisionist anthropologists, and many others (Headland, 1997) were reacting against the widespread tendency of some environmentalists and deep ecologists to attribute a mystical oneness with nature and an ecological nobility to tribal peoples. The mistaken implication of such romanticism of the human past, would be that our only salvation is a return to the Stone Age. This is a misleading issue because anthropologists have abundant evidence that tribal peoples were pragmatic materialists who burned on a large scale, sometimes killed more animals than they needed, felled trees to harvest fruit, and were not always guided by the spiritual sanctity of nature. There is also evidence that prehistoric humans hunted some animals to extinction, and may have contributed to the extinction of the Pleistocene megafauna, such as New World elephants, although there is much controversy on the details (Martin, 1984).

These facts need to be viewed in a larger perspective. The reality is that until 8000 years ago, when the world was still domestically organized and inhabited by only 8 million people living mostly in mobile bands at extremely low densities, there was no need for deliberate conservation practices. Likewise, optimal foraging theory suggests that intentional over-hunting would have quickly proven unproductive, because as prey species become scarce, hunting them becomes inefficient (Smith, 1983). Archaeological evidence that Australian aborigines successfully lived as hunters and foragers for at least 60 000 years (Roberts *et al.*, 1990), and that aboriginals in Southern Africa successfully survived as a people for 130 000 years (Klein, 1979) leaves little doubt that people living in very small-scale societies produce resilient cultural systems able to maintain very long-term balances with their natural resources. The archaeological record needs to be compared with the estimates at the end of the twentieth century showing a high proportion of plants and animals threatened with extinction, or nearing threatened status (Baillie and Groombridge, 1996; Tuxill, 1999). Nothing in human prehistory or history compares with the present rate of global environmental change.

It is remarkable that the scale of global change corresponds directly with increases in the scale of culture. This was dramatically confirmed by the ARCHAEOMEDES project, an interdisciplinary investigation of 30 000 years of environmental change in the Mediterranean region initiated by the European Union in 1992. Researchers found that the measurable rate at which land degradation could be observed from land clearing, erosion, and dessication increased progressively by orders of magnitude from tens of millennia during the Paleolithic, to millennia during the

Neolithic, to centuries during the Roman era, and to decades under industrial capitalism since 1850. In one region of Spain, researchers found that half of all the erosion over the past 10 000 years had occurred in the past 500 years, and it had accelerated over the past 150 years (Leeuw, 1997).

THE DRIVING FORCES BEHIND GLOBAL ENVIRONMENTAL CHANGE

The most widely accepted anthropological explanation for the rise of cultural complexity and intensi ed environmental problems has been population pressure on carrying capacity. Carrying capacity must be de ned in relation to particular environments and technologies, and is not a constant (*see* **Carrying Capacity**, Volume 4). Population pressure is also a variable that can be different under different consumption demands and distribution patterns. Nevertheless, population pressure remains a powerful explanatory model. It is a variation on Malthus (1895) observation that population has the potential to grow at a faster rate than food production. Population pressure and subsistence intensi cation have been used to explain the Mesolithic to Upper Paleolithic transition (Hayden, 1981), the domestication of plants and animals leading to the transition from the Upper Paleolithic to the Neolithic (Cohen, 1977), increased energy input and technological innovation in agriculture (Boserup, 1965), and the origin of the state and civilization (Carneiro, 1970; Steward, 1949). All of these changed the environment. Population pressure has also been explicitly linked to contemporary environmental problems (Ehrlich, 1968; Homer-Dixon, 1991).

The problem with all of these population pressure explanations is that often they do not explain population pressure itself, and they do not deal with the social inequality that also produces scarcity. The archaeological record demonstrates that for most of human prehistory population growth was minimal, not because of high mortality, but because fertility was culturally limited (Hassan, 1981). In domestic-scale cultures in the absence of political pressures women opted for small families, because extra children were a disadvantage. Only in politically organized and commercial societies are there strong externally imposed incentives for population growth. When anthropologists have looked at extreme examples of supposed population pressure producing environmental stress and human misery, whether in Bangladesh (Hartmann and Boyce, 1982), Brazil (Scheper-Hughes, 1992) or El Salvador (Durham, 1979, 1995), they have found that social inequality, not population, was the problem.

Viewed from a culture scale and biocultural evolutionary perspective, the driving force behind global environmental change is the natural human desire of individuals to improve the material security of their households under cultural conditions of economic scarcity produced by social inequality and competitive striving. The important point is that economic scarcity and environmental problems are produced culturally by social inequality, they are not natural conditions.

ANTHROPOLOGISTS, INDIGENOUS PEOPLES, AND ENVIRONMENTAL CHANGE

Cultural ecological researchers have often helped indigenous people defend their ecosystems and natural resources against deterioration caused by the uninvited intrusion of outside commercial interests. The most important anthropological support, from both archaeologists and cultural anthropologists, has been in helping indigenous communities document their long-term use of particular places and resources, in order that extensive, traditionally owned and used territories can be legally titled to communities and protected. In some cases it has been useful to document that traditional uses were sustainable. Anthropologists have also helped demonstrate that indigenous communities have highly developed knowledge of their ecosystems, including the names and natural histories of plants and animals. Some indigenous communities have asked researchers to help them with the dif cult problem of managing natural resources for both subsistence and commercial uses. Other communities have sought to protect portions of their territories for eco-tourism (*see* **Indigenous Knowledge, Peoples and Sustainable Practice**, Volume 5).

Art and the Environment

Peter Timmerman
University of Toronto, Toronto, Canada

This artistic dimension of global environmental change is complex and underexplored. It ranges from the roots of the

artistic impulse in human beings that impels them to explore, shape, and 'make their mark' on the world; to the artefacts in art, music, architecture, gardens, etc., that result from this impulse. If art is often what human beings make when they are at their freest and most creative, it also thrives on the transformation of the real, the material, the tightly constrained into works of art that capture some otherwise inexpressable element of the nature of being in the world. We can see that the artistic expression of the environment is always happening; but it seldom expresses itself directly. The dynamic pressures of global environmental change are similarly nding their way into the arts of today's world. Today's artist is a direct inheritor of the Romantic idea that the great artist (or the great work of art from the great artist) is some kind of 'antenna of the race': and apart from the elemental human delight in art, we can also explore art for its extraordinary capacity to intimate the deeper undercurrents within what has happened, is happening, and is to come in the world around us.

The following article deals primarily with the artistic impulse in general (primarily in painting). See ***Landscape, Urban Landscape, and the Human Shaping of the Environment****, Volume 5 for more details on a related topic.*

ELEMENTS OF ART AND THE ENVIRONMENT

The earliest artworks we have are symbolic of many aspects of the arts and the environment, including global environmental change. The cave paintings in Altamira, Spain, Lascaux, France, and elsewhere, which date from roughly 35 000–15 000 years ago, depict on their walls large herds of animals that were soon to be extinct; and the movements of those herds can be linked to the progress and retreat of the ice sheets of the last ice age. Perhaps of even more relevance is the fact that we cannot say what these exquisite works of art were for. We can call them art, but there are various theories of their purpose; charms to increase the herds, sympathetic magic to give the hunter some control over the beasts, an expression of spiritual kinship with the animal world, or simple delight in being able to represent them.

This mysterious entrance into the relationship between the arts and the environment persists. The most obvious aspect of this relationship is representation, the picture of a tree or an animal that impresses us because it looks like, or at least reminds us, of that which is being represented. There seems to be a basic human delight in the power or playfulness of drawing or painting an image of something else on a different medium. But there are other aspects of the impulse towards art that are at least as important; and, given that many people are now familiar with abstract act, it is clear that art is not all about lifelike pictures. Among the main aspects of the artistic impulse worth considering are:

- the medium, that is, what is the basic material in which the artist is working, its characteristics, its limitations, its possibilities.
- The content, that is, the subjects, themes, or ideas that the artist is using the medium to express.
- The role played by the work of art, that is, is it a picture for sale, a building for living in, a ritual mask for a dance, or whatever.
- The audience, who the work is for, if anyone; and, lastly,
- the artistic impulse and expression, the capacity to create.

THE ARTIST AND THE ENVIRONMENT

In considering the arts and the environment, we can look at the last of these aspects first, since it will give us a perspective on the tensions and dynamics of artistic expression. In his pathbreaking book, *Playing and Reality*, the child psychoanalyst D W Winnicott (1963) argued that when infants begin to deal with the world, they are initially immersed in an non-separate environment, since they have not yet created a sense of themselves as individuals. The separation into selves (primarily mothers and children) takes a long time, and the fears and tensions involved are often handled through play. Play is the crossing backwards and forwards across boundaries that are in part created and discovered through play. A child learns how to move, what things break and what things don't, and what actions will get punished (or rewarded) and by whom. Play is the process whereby this can happen without too much danger.

For Winnicott, the ability to play is central to the creative process. He sees that, among the problems children (and artists) face are the times when their play is somehow constrained, or becomes truly dangerous, or the transition to reality is somehow thwarted. In many ways, the artist is someone who seems to be able to keep the impulse to play with the materials, boundaries, and environment around him or her into adulthood. It is this which helps to explain their ability to make connections that have not been made by others; to be humorous about or threatening to the *status quo*; and occasionally to provide insights into worlds that some believe to be beyond human boundaries. At the same time, this ability has often been seen as unholy or dangerous; and there is a consistent thread running through the history of artistry as being to madness near allied.

EARLY ENVIRONMENTAL ART

This initial focus on the artist is somewhat misleading, since not only do we have no records of individual artists for many centuries; but the whole idea of the artist is a

somewhat modern or romantic casting of the topic towards the individual. Nevertheless, the idea that the creative impulse is associated with the playing with or negotiation of boundaries in one's surrounding environment can be very fruitful.

Many of the cave animal paintings can be seen to respond to the cracks and crevasses of the walls, humps of animals being painted on outcroppings of walls, etc. In other animal and spirit paintings from around the world, we can also see that there is a kind of intimacy with the physical material supplied by the environment. For instance, in the Peruvian desert south of Lima, there are vast geoglyphs (earthmarks) believed to be about 4000 years old including animal and geometric patterns, hundreds of meters in size. Many aboriginal communities engaged in making petroglyphs (stone marks) and other paintings both above and below ground.

This *earth art* (which has recently been resurrected by contemporary artists seeking to express concerns about the environment) is, as already mentioned, possibly linked to various kinds of spiritual ritual or magic. Anthropological research in the last 200 years has shown that in many kinds of spiritual ritual or magic, a symbolic structure is established linking the patterns created by the tribe or priesthood or shaman on the earth with the spiritual realm. It is very important to recognize that the strong boundaries between the human, the animal, and the spiritual worlds that are characteristic of contemporary Western life would be seen as bizarre to virtually all other peoples in the history of the world. Rather, the boundaries between these worlds or realms were seen as permeable and changeable and transitory.

The sacred spaces and sacred times set up by rituals were often designed to mimic the underlying order of the cosmos, and the artistic artifacts (masks, images, music, dancing) as aspects of that order; or as a part of the continuing conversation with the spiritual world. This role of the art object persists, not only in the familiar paintings of the Madonna and Child over the altars of many Christian churches around the world, but also in the residual feelings of people when they look at a Cezanne painting and somehow sense that they are in touch with some deeper aspect of reality as portrayed by a dish of apples.

When we look at the origins of architecture, we can see that the megaliths of ancient Europe (like Stonehenge), the great temples of the Mayans, and the vast Pyramids, all have connections and orientations towards the sacred and the spiritual. Even in domestic architecture, the elementary forms of building (walls, roofs, spaces for entrances, exits, etc.) mingle the utilitarian with the orientation towards meaning; the hearth, the shrine, the basic axis of the village or town.

Much of the official art that survives, associated with the large kingdoms of Egypt, Sumer, Assyria, etc., of the ancient world, depicts the natural world in accordance with some aspect of the ritual needs of the societies involved, though there is obviously some delight in the excellence of the craftsmanship and artistry involved in these depictions. For example, in Egyptian art, such as the palette of King Narmer, *circa* 3000 before the Christian era (BCE), or mural panoramas of voyages down the Nile (or the river of Death), one finds a sensitivity to the lush river world, and to the dignity of animals (many of which were worshipped as gods). Assyrian art, depicting the hunting and killing of lions and other animals, glorifies the powers of the all-conquering king, but also depicts the throes of the animal as well.

ART AND THE ENVIRONMENT IN THE CLASSICAL AND MEDIEVAL PERIODS

Art historians are confronted with some severe difficulties in dealing with representations of the environment in the classical arts of Greece and Rome, because so little painting remains apart from mosaics and some paneled rooms. These tend to favor the decorative and the pastoral (the pastoral being an art form that evokes the rural retreat of the wealthy from the increasingly dirty town). Much of the rest of landscape representation is symbolic or serves as a backdrop to human endeavors.

In Greek culture (epitomized by the flourishing of Athens from 600–300 BCE), landscape as a theme is practically non-existent, except in two areas: the continuing presence of the pagan gods of nature in certain forms of nature (e.g., the home of the gods on Mount Olympus) including the local gods of place; and the appearance in the Hellenistic period (after 300 BCE) of the beginnings of proto-sciences such as geography and epidemiology that obliquely made reference to natural forms and processes. From later Roman paintings (often copies of earlier Greek artworks), we can recover a variety of versions of pastoral, the rural scene, and make-believe landscapes illustrating mythological scenes from Homer or other legends.

Through the period of the Roman Empire, there continues this somewhat haphazard interest in nature. The arrival of Christianity had a twofold effect: first of all, as Christianity became more powerful, it systematically destroyed as much of the previous pagan tradition (including pagan shrines and holy groves) as possible; and second, it emphasized even more strongly the peripheral role of the natural world. What was now central was the spiritual struggle of Man towards God, and the natural environment was replaced by the spiritual environment. Images of animals or plants (when they did not appear as marginal decorations to manuscripts) were saturated with symbolic reference, exemplified by the sheep and the shepherd that can be found portrayed around the cupolas of Byzantine churches.

While there were breaks in this artistic tradition (most notably with the reevaluation of the natural world associated with the figure of St. Francis of Assisi *circa* 1200 AD), it is not really until the arrival of the Renaissance in the 15th century that the natural world by itself is seen as anything other than a space of symbols with no inherent interest of its own, though it was occasionally connected to the power and splendor of an all creating Deity. Indeed, in the evolving tradition, Nature became more and more seen as a wild space, symbolic of the spiritual dangers of wilderness and irrationality.

If we look brie y at the neighboring world of Islam, which ourished in the Middle East from the 7th century, and provided a strong challenge to the medieval West, we nd that while images of nature were banned from representation, the whole tenor of Islam in this period led to extraordinary advances in science, geography, history, astronomy and chemistry. Islam was much more favorable to the exploration of nature as an expression of the signs and symbols of Allah than Christianity in this period. Unfortunately this does not appear overtly in the artifacts that survive from that time, which are almost completely made up of abstract decoration (derived, in part, from the example of beautiful cursive patterns of Arabic writing of passages from the Koran). Later developments (in the 14th century and after) in, for example, Persian miniature paintings that do contain landscapes were in uenced by Chinese paintings (Islam connecting with China down the long trade routes).

ART AND THE ENVIRONMENT IN THE ORIENT

Some reference should be made to artistic expression and Nature in the Oriental world, speci cally China (Chinese principles in uenced the arts of Korea and Japan, and make it an appropriate single example of a vast topic). There are two main ideas at work in those Chinese arts associated with environment, which include such arts as *geomancy* (known as *feng-shui* or the appropriate placing of buildings and parks), poetry, and landscape painting.

The rst idea, which eventually becomes associated with the spiritual tradition of Taoism, but which goes back to the dawn of Chinese civilization, is that there is no separation between the order of the natural world and the order of the moral or social worlds. There is a kind of natural moral order in the world, called *the Way*, *the Tao*. Human dif culties come from straying away from that order. Similarly, proper balance of natural forces will help to improve the moral world. For instance, mountains and water are like interacting opposites (what the Chinese refer to as *yin* and *yang*) (*see* **Land Transformation in China: 3000 Years of Human Ecological History**, Volume 3); the height of the mountain balances off the depth of the water; the movement of water contrasts with the stillness of the mountain. The placement of dwellings, and the contemplative isolation of the scholar or monk, all rely on the balancing energy of natural elements.

The second idea, associated with the philosopher Confucius (*circa* 600 BCE) and his in uential descendents, is that the natural, moral, social, and political orders should all be in harmony, and that the central pivot of this harmony is not necessarily the natural order, but rather the cultivated order of the nobleman (or ruler). Confucius occasionally uses natural imagery, one of his sayings is that The wise delight in water; the good delight in mountains , referring to the balance between appropriate action and the stability of the ancient state and rules of justice, but his emphasis is on the cultured order. This approach was particularly in uential in the extremely elite cultures of the T ang (618 907 AD) and later Chinese dynasties saturated with Confucian thought.

The artistic expression of these ideas is most familiar in the Chinese landscape scrolls, which unfold vast misty landscapes expressing Taoist environmentalism; in which tiny meditative gures or rustic shermen can occasionally be picked out. Many landscapes (and later gardens associated with this artistic impulse) also gesture in the direction of the Taoist Lands of the Blessed: the future Paradise within which all will dwell. The tiny gardens that can be found around Chinese and Japanese Buddhist (and Taoist) monasteries and temples attempt to reproduce in stones, mosses, sand, and miniature trees, the vision of these lands.

In painting, the poetic and the theoretical meet in artists like Wang Wei (699 761 AD) whose long poetic sequences unfold along with extensive landscapes that the viewer wanders through. Further, the very materials and acts of painting are resonant with orientations toward aspects of the natural order whose penetration is essential to the greatest art. Often the artist is exhorted, through disciplined exercise, to submerge or eradicate the self, allowing the larger natural order to speak through the brush. This contrasts with the very different stance taken by the Western artist (at least until the modern period).

ART AND THE ENVIRONMENT IN THE RENAISSANCE

The Renaissance period (1450 1600) in Western culture saw the beginnings of a reevaluation of the natural world, in part due to a series of struggles over the legacy of Aristotelian science which began reappearing in the West in the 12th and 13th centuries (many of the scienti c writings of Aristotle and other Greek philosophers with an interest in the workings of nature had in fact been preserved by Islamic scientists). The ferment and cross-fertilization between this Aristotelian science and the already existing Christian

tradition (based in large part on a neo-Platonic base) would eventually lead to the growth of an experimental tradition that overturned the whole medieval world view.

Curiously enough, the artistic signal for this ferment came about in part as a glorification of the perspective of the individual observer, thanks to the invention of perspective in the 1400s. Previous to this, the presentation of space in paintings was shaped by meaning (for instance, more important people would be higher in the paintings) and not by any desire for accurate representation. Perspective introduced the eye view of the spectator as a standard from which, by simple geometric rules, a consistent space could be generated within which landscapes, buildings, cities, etc., could be organized. The irony is that this space, which provided a methodology for representing nature in such a convincing way that it has become totally natural to us, is in fact an abstracting of space. Every space is treated the same: special or sacred places no longer influence the world of representation within which they are portrayed.

We can link this development of a framework of abstracted space to the similar and simultaneous development of abstracted time with the arrival of the mechanical clock. In the architecture and painting of the Renaissance, we see the twin drives of clarifying and ordering of spatial representation. This new power provided artists with the capacity to explore, almost as if they were early scientists, the phenomena of light and shade, as well as the dynamic portrayal of weather, water, and the atmospherics of distance perception (for instance, the bluing of color as a landscape retreats away from the viewer). Leonardo da Vinci is of course the most famous representative of this, and in his paintings as well as his manuscripts, we can see the probing mind of the artist who uses his art as an exploratory tool into different fields, like anatomy, mechanical engineering, and ballistics.

For environmentalists, this new power can be seen as a double-edged sword. For it is in this period that the new methods of representation become allied to the emerging forces working towards the control and reshaping of the natural environment. This was part of the restructuring of what could now be called the early modern world, which wrested control from the Church and vested it in nation states. These states embarked on a quest for power, which has not ended yet.

The most obvious of the ways in which the arts were associated with this quest included the arts of mapmaking (essential to the management of the new lands associated with the voyages of discovery; see e.g., Delano-Smith, 2001), theatrical and painterly spectacle (ranging from the glorifications of the church in the various projects in the Vatican to the various historical allegories by Rubens for the French and English kings), and the architectural grandeurs of St. Peter's Basilica in Rome.

Less obviously, the art of the period increasingly focuses on the autonomous individual who walks through a world of his own creation; or at least his own substantial manipulation. Even that seemingly most natural of all painting genres, the landscape, which originates in the Netherlands (a new state of the era), and which is characterized by the absence of human beings in a central role in the depictions, cannot get away from the fact that the picture is designed to be seen according to the rules of perspective, which require the observer to hold the whole scene together.

Towards the end of the 17th century and into the 18th–usually known as the Age of Reason or the Enlightenment–a further tension was added to the depiction of nature with the arrival of the powerful abstract notions of Newtonian time and space, and the emerging image of a physical world subjected to absolute laws of physics. This coincided with the rise of the absolutist state, whose most familiar artifact was the formal garden at Versailles, home to the Sun King', Louis XIV of France.

The great landscape artists of the period, such as Claude Lorrain (1600–1682) and Nicholas Poussin (1594–1665), depicted landscapes derived from classical history and mythology, which provided the viewer with images from an idealized memory of a Roman or Greek past that might be reproducible again. As the Age of Enlightenment continued, the ideal emotions (of virtue, duty, obedience, reverence to noble ancestors) symbolized by these paintings began to be superseded by less restrained emotions and sentiments. In hindsight, we can see that these emotions, like a breeze fluttering through the leaves of pastoral scenes, were the forerunners of the greater storms that would usher in *Romanticism* (1750–1850).

In the run up to Romanticism (which is the seedbed for modern *environmentalism*) the role of nature as depicted in paintings and articulated in poetry and literature, oscillates between the emerging picture of a universe structured like a vast clockwork operated by an increasingly distant maker; and a related, but different picture of human beings connected to each other and to nature by sympathetic and empathic emotions or sentiments; captured in poems like James Thomson's (1700–1748) *The Seasons*, where each season influences the sensitive soul. With hindsight, we can see that this oscillation is an uneasy solution to the deeper problems associated with the imaginative consequences of the final breakup of the old world view that had buttressed the old world for so many centuries.

ART AND THE ROMANTIC ENVIRONMENT

This previous world view, which had supported the social and political order of things through an ascending pyramid of order and control which was felt to reflect a divine order of increasing rationality and access to higher truths, came

to be seen increasingly as bogus or at least out of date when confronted with newly restless (and increasing) populations, the redrawing of the maps of the world and the cosmos, and the surging potential for scientific enlightenment. Artists found themselves not only profoundly influenced positively by the vast increase in human capacities to harness energy through science, technology, and industrial organization; but also profoundly worried about the consequences of aspects of that harnessing in the disruptions of the Industrial Revolution. The Romantic Revolution was, for artists, simultaneously an exultation of what was now possible for the individual or the awakened community, throwing off its ancient fetters; and a dark warning about the repressive possibilities of new powers in new hands.

Politically, this helped propel the revolutionary struggles of the French Revolution (1789), an essential moment in the rise of modernity. Artistically, the Romantic artist fastened onto the idea of the artist himself (and now for the first time practically, herself) as the embodiment of the alienated human being in a world being transformed by factories and machines. The creative artist was that special form of the alienated human being whose antennae or capacities were capable of bridging (after creative or political struggle) the emerging gap between the self and the outside world, being given over increasingly to industrialization. The allies of the alienated human being in his or her struggle could most obviously be found in the similarly struggling realm of nature, since nature was herself becoming more and more subjected to forces of mechanization and alienation. At the same time, however, natural places could provide a refuge from the increasing power of human technology.

The continuing landscape tradition in art was obviously an important vehicle for these emerging themes. In 1757, the English philosopher Edmund Burke wrote his immensely influential treatise on aesthetics, *A Philosophical Enquiry into the Origin of Our Ideas of the Sublime and the Beautiful*, in which he crystallized an emerging theme of the period, which was that the natural world was, among other things, potentially a place of emotional (sublime) power; for example, the sense of overpowering awe at the sight of Niagara Falls. This was, as it were, the most powerful way to overcome the split between human and nature: by the shock of brute natural experience.

Landscape as a symbol or a carrier of emotion was central to the 18th and 19th century paintings of Gainsborough, Constable, and Turner in England, Caspar David Friedrich in Germany, the Barbizon School in France, and others. Some of the themes of these paintings include:

- vast mountains, waterfalls, landslides, or immense forests within which the human presence is dwarfed or muted into meditative silence (Turner; Friedrich);
- nostalgic scenes of ordered country life, before the onslaught of industrialization (Constable);
- Oriental, historical, or classical landscapes that are far from contemporary life (Corot; Bonington; Delacroix);
- the simple rustic life of peasants and farming (Millet; the Barbizon school).

The whole range of Romantic nature portrayal in art was simultaneously reinforced by similar themes in Romantic poetry, music, novels, etc. The sensitivity towards nature was a barometer of one's personal sensitivity; and often of one's politics.

The most important English writer on art and the environment in the 19th century was unquestionably John Ruskin. Ruskin was a central influence on a number of continuing themes, such as the return of Gothic style architecture to public buildings, the emphasis on handicraft work (that would be picked up by William Morris later), and various campaigns to save monuments (such as St. Marks in Venice). His greatest claim is probably that he taught a couple of generations of artists and writers to engage in the intense study of natural forms and details. Ruskin believed that in the details of natural forms could be found spiritual patterns and truths, and that they were portals of self (and social) awakening.

The descendants of Ruskin include not only the Pre-Raphaelite painters of his own day, some of them who were committed to Ruskinian detailing in their work, but much later photographers like Ansel Adams who specialised in intensely grained portraits of natural objects like rocks, trees, and waterfalls. The mention of photography also reminds us that in Ruskin's day artists were being challenged by the new phenomenon of the photograph that could capture details of the world in an instant, details that might take days or weeks to obtain on a canvas.

The French Impressionists, though in many ways quite different than photographers in their aims, nevertheless found themselves often engaged in kinds of work allied to at least some of the tendencies that could be found emerging (over time) in photographic aesthetics. Among these were the emphasis on the immediate response to a scene; the organizing of a scene by light, shade, and color rather than by underlying physical structures or the rules of classical perspective; and the increasing use (particularly by Degas) of seemingly accidental frames around scenes so that pictures began to look as if they were sudden glimpses into reality rather than long-meditated artifacts.

In a sense, the Impressionists were the culmination of the Perspective Project, except that their observer was acutely sensitive to the immediate atmospheric environment, so that form begins to dissolve into light, color, and seasonality, as in Monet's late studies of Rouen cathedral and haystacks at different times of year. Almost immediately, this dissolution was countered by returns to certain kinds of classical formalism (as in the paintings of Cezanne),

and the deploying of forms and visual elements generated, not by the physical world, but by symbolic or emotional expressiveness. The most famous examples of these are the late works of Vincent Van Gogh, whose Sunflowers are simultaneously visionary piercings into the primal energy of the natural world, and also expressions of the artist's own emotional vocabulary of line and color. Cezanne, too, in his intense study of the modeling of natural objects, finds himself pressed into creating a painting language remote from the previous conventions of representation.

ART AND THE MODERN ENVIRONMENT

It is a truism of art history that the late 19th century pressed the traditional norms of representing the natural environment to their limits; and that Picasso (drawing on the work of Cezanne and others) broke those norms completely. *Modernism* in art, literature, and other areas, was exemplified by the collapse of a primary logic of correspondence. In a logic of correspondence, x and y in the artwork correspond to X and Y in the world, and that is how representation works. This is replaced by a logic of coherence, where the internal coherence of the elements of the artwork is more important than their potential correspondence to an outside world. A novel like James Joyce's *Ulysses* (1922) gets much of its power from its one-to-one correspondence to a day in Dublin, it is the last gasp of the traditional novel. Joyce's last novel (modernist or postmodernist), *Finnegans Wake* (1941) has only the vaguest external reference: its structure is internal (and in fact, the novel, if it is a novel, has no beginning or end, but is circular).

Similarly, the most avant-garde artistic expression moves away from simple representations of the natural world, just at the moment when photography makes such representations normal, and in fact begins to provide representations of parts of the natural world unrepresented before, thanks to time lapse photography, microphotography, satellite photography, etc. Typically, a modernist painter like Marcel Duchamp, in his *Nude Descending A Staircase No. 2* (1912) will use images derived from the work of Eadward Muybridge's photosequences of movement. But he will use them to pattern the movement of descent of a figure so that it breaks up what would (in traditional art) have been a frozen moment on a stair.

There may be some relationship (though this is extremely controversial) between the coherence model of modern art and the virtual disappearance of landscape from the artist's repertoire for about 50 years following the arrival of Picasso on the scene. It survives overtly in the warped or dreamlike images of the Surrealist painters, and the cool urban spaces of the American painter Edward Hopper. Nevertheless, the art historian is aware that *abstraction*; which appears to be the most unrepresentative art of all; abstraction (associated with Wassily Kandinsky, Piet Mondriaan, and others), originated in a complex desire by these artists to abstract from the real world deeper spiritual and emotional forms than could be captured simply by representational pictures. The abstract painting often can be seen as a formal or emotionally expressive landscape (an interior landscape of the mind, or simply of the possibilities of the basic elements of paint itself) canvas, color, light, frame, etc. Certainly, throughout the modern period there have been artists engaged in representative art, but until recently, they were completely marginalized. Interestingly enough, it is in marginal forms like watercolor that many artists of nature (Winslow Homer, John Singer Sargeant, Andrew Wyeth) and many nature artists (that is, wildlife artists) worked.

One critical fact about the modern artist is his or her sophistication with regard to all previous forms of representation. The way in which artists will subvert photographic realism, for instance, or tease the viewer with false hopes that x will indeed represent X, all serve to highlight, or undermine the norms of visual representation. This kind of approach, pioneered by the Dada artists during the First World War as an attack on the kind of normalcy that could have generated a world war, fixed on photomontage and collage as possible subversive forms. Pop art, in the 1960s, worked variations on this. Today, on many fronts, artists are engaged in a kind of guerilla warfare against the juggernaut of stale or compromised images that are constantly regurgitated through the marketing machines of the economic system. A kind of anti-art can be seen wherever environmental activists are to be found; posters, parodies of advertising campaigns, cartoons, expressive collages, etc.

THE RETURN OF EARTH ART

The advent of Earth Art or Eco-Art was in many ways a reaction to certain aspects of modernism (particularly those parts of modern art that seemed to be complicit in those parts of modernity that are threatening to the natural world), but are also rooted in an artistic sensitivity to the increasing burden of global environmental change.

One distinct element of modern art has been a devotion to abstract or formal structures whose relationship to an external world are not necessarily immediate or conventional. Among the results of this in the buildings associated with the International Style (from the late 1920s) e.g., was a kind of unrooted geometricization of form and structure; i.e., you could build a perfectly formal skyscraper anywhere in the world. The best architects would, of course, relate their efforts in subtle ways to their surroundings; but the vast burgeoning of big box buildings, and the complacent hubris of post World War 2 urban planning generated (at least

among certain artists and architects) a revulsion towards the whole ethos associated with what was increasingly referred to as The Modernist Project . This Project was seen as deeply rooted in a kind of unstoppable juggernaut of capitalist development, mingling engineering, planning, market economics, and the rhetoric of democracy together into a completely seductive paradigm.

The revulsion against this has taken many forms, from the guerilla art forms already mentioned, to attempts to resuscitate a local dimension to art, architecture, and sculpture; to recover a sense of place, as well as space. This has been embodied in different forms in different arts. For example, in sculpture, some people have taken their cue from Henry Moore and Barbara Hepworth, who worked in organic forms, and were very sensitive to the relationships of human beings in the environment; while others have explored the long tradition of the monument in the landscape, the obelisk, temple, pillar. The mutual transformation of monument, landscape, and human observer has been explored in Environmental Sculpture (sculptures that are large enough to create an environment within which the observer moves) and in the very influential Earth Art.

Earth Art is in many ways a return to the glyphic projects of early humankind, exemplified by the earthworks in deserts, on mountain tablelands, and in caverns. Robert Smithson's great earthworks (like Spiral Jetty on the Great Salt Lake in Utah) and Christo's wrapping of landscapes and buildings, are different ways of highlighting the tensions created by our contemporary abilities to reshape the earth for our own purposes.

As Lee (*see* Landscape, Urban Landscape, and the Human Shaping of the Environment, Volume 5) further discusses, there are numerous variations in what contemporary artists have seized upon in our situation. To give only one example of something that might contrast with the grand scale of a Smithson or a Christo, an artist like the Chilean Cecilia Vicuna collects shells, wood, pieces of wool and vicuna (!) in what she has called precarious art; tiny pieces of nature rescued for a moment (Merewether, 1992).

It is worth also pointing out in this context that there is a widespread greening going on, most notably in architecture. With new interests in: local or vernacular buildings that were always sensitive to its environment out of necessity; in new technologies for building, heating, cooling, and otherwise improving the efficiency of buildings; and in living buildings with roof gardens, greenhouses, and other natural process devices (*see* Greening of Cities, Volume 3). There are also basic concerns with recycling, the use of chemicals in painting, and so on, that are now part of the consciousness of most artists.

CONCLUSIONS

This review of the vast array of artistic responses to environmental change has focussed on the main line of artistic endeavor. An equally brief, but completely different review, might focus instead on the art of what Westerners would consider to be marginal peoples (traditional crafts, indigenous arts, and unofficial art of all kinds) whose arts both speak of different relations to their environments, but are also more and more subject to the complexities of living in a world becoming saturated with the visual and aural products of Western commercial culture.

A third review would ignore the past almost completely, and report from the artistic trenches of today, exploring the experiences and expressiveness of artists, still acting, as the poet Percy Bysshe Shelley once described them, as the unacknowledged legislators of the race. Their ability to capture and portray aspects of reality that we have not seen before, is one reason why they are so important to us. But it is also easy to overplay that, as well; as if artists have to be spokespeople for anything. It is not clear (if it ever was) what the role of the artist is (or what art is for, if anything) but, as an artist friend of mine once said: You know that canary in the mine? Everyone always says that it was there as a warning for the miners. I think they had it there for that purpose; but I'll bet they liked hearing it sing, too.

Attenborough, David

(1926)

David Frederick Attenborough, British naturalist, author and broadcaster, has done more than any other person to popularize and create an interest in natural history in the UK and in many parts of the world through his many television programs and series produced by BBC television. After serving in the Royal Navy from 1947 1949, he joined the staff of an educational publishing house. In 1952 he moved to the BBC as a trainee producer and soon established his reputation through his famous *Zoo Quest* series, aired from 1954 1964, which took the viewers to many remote places Sierra Leone (1954), Guyana (1955), Indonesia (1956), Papua New Guinea (1957), Argentina and Paraguay (1958), the Southwest Paci c (1959), Madagascar (1960), northern Australia (1962) and down the Zambesi from source to mouth in (1964). His next series was *Eastwards with Attenborough* set in Southeast Asia followed by *The Tribal Eye* which examined sculpture (one of his hobbies), weaving, metal casting and other tribal activities around the world. He received worldwide acclaim and the British Academy of Film and Television Arts Desmond Davis Award for his 1979 13-part series *Life on Earth*, then the most ambitious series ever produced by the BBC Natural History Unit. This was followed by *The Living Planet* series in 1984, and *The Trials of Life* in 1990, which dealt with animal behavior. His series *The First Eden* was a survey of the impact of humankind on the lands around the Mediterranean, which was followed by *Lost Worlds, Vanished Lives*, a series on fossils. A popular series was *Life in the Freezer*, about wildlife in the Antarctic (1990). He treated plant life in *The Private Life of Plants*, which was aired in 1995. His most recent series in 1998 was on birds of the world. In this long record of natural history broadcasting, Sir David has treated many aspects of biodiversity and has drawn attention to the fragile nature of natural ecosystems, which has stimulated interest amongst many different audiences. Sir David was knighted in 1985 for his services to broadcasting, was made a commander of the Royal Victorian Order in 1991, and a companion of honor in 1996. He has received honorary degrees from many universities including Cambridge, where he studied for his rst degree in natural sciences from 1945 to 1947. He was elected a fellow of the Royal Society in 1985, the year in which he also received the Founders Medal of the Royal Geographical Society. He is the recipient of the International Cosmos Prize 2000. He has received many other awards and medals including an International Emmy Award in 1985. He has served as a trustee of the British Museum, the Royal Botanic Gardens, Kew and the Worldwide Fund for Nature and a President of the British Association for the Advancement of Science. Sir David s hobbies include music, tribal art and, of course, natural history.

His books include: *The Private Life of Plants*, BBC (1994), and *The Life of Birds*, BBC (1998).

B

Baha'i Faith and the Environment

Richard M Landau
Georgetown, Ontario, Canada

This article explores the basic principles and beliefs of the members of the Baha'i Faith and then examines how these can and are being applied to environmental and development challenges worldwide. Starting with a brief exploration of the basic spiritual tenets enunciated by Baha'u'llah, the prophet-founder of the Baha'i Faith, this article examines the Baha'i prescription for resolving the dif cult challenges before humanity. The Baha'i Faith began in the nineteenth century in Persia and today numbers over six million adherents worldwide. Baha'is believe that all world religions originate from a common divine source and that Baha'u'llah was the messenger from God for this era. Contained in his teachings are speci c measures to usher in a new world order based on spiritual principles.

The article concludes with an exploration of the participation of the Baha'i International Community (BIC) in the United Nations (UN)-sponsored initiatives as well as a range of development and environmental projects undertaken by national and local Baha'i communities.

The author has been a member of the Baha'i Faith in Canada since 1973 and is a graduate of Carleton University and the University of Ottawa. A leader in interfaith dialogue, Mr Landau is author of "The Willing Suspension of Belief: How the World's Religions Can Work Together."

The Baha'i Faith, which was founded in 1863, is the world's second most geographically widespread religion with more than six million adherents living throughout the world's nations, territories, islands and outposts. Following the example and teachings of their prophet-founder Baha'u'llah (AD 1817–1892), the world's Baha'is consider themselves to be the citizens of one country. Baha'is regard the world as one organic unity.

The Baha'i Faith considers the monotheistic world religions part of an ever-advancing continuum that has a design. Each religion, they assert, has its origins in a common source or Godhead. A covenant exists between God and humanity whereby God reveals his plan gradually through his messengers. This is the fountainhead of human progress. Thus, from time to time, God sends forth prophets with revelations appropriate for a specific people at a specific period of human development. In keeping with the idea of this progressive revelation, often the laws and customs of preceding revelations are abrogated with the advent of each succeeding religion. For Baha'is, Baha'u'llah has revealed God's message to humanity for the current age; an age which will be characterized by world unity.

Baha'u'llah (translated as The Glory of God), who was born in Persia, revealed numerous volumes of scriptures and laws upon which the Baha'i Faith is founded. He lays claim to being the most recent in a line of chosen messengers from God that includes his immediate precursor known as The Bab (translated as The Gate), Mohammed, Jesus, Moses and Abraham as well as Zoroaster, Buddha and Krishna. The Bab (1819–1850) who was born in Shiraz, Persia revealed in 1844 that he was the gate for one greater than himself who would begin his mission to humanity in 1863. Ecclesiastical and civil authorities in Persia, alarmed by the rapid growth of the Babi movement and The Bab's claim to a revelation from God, persecuted his adherents and martyred The Bab on July 9, 1850. Likewise, because of his teachings, Baha'u'llah spent his adult life in prison and exile in various outposts of the Ottoman Empire, finally living out his last days under house arrest in the port city of Akka, near Haifa, Israel.

While the Baha'i Faith has its origins in Islamic Persia, it is a discrete and independent faith that claims to represent the fulfillment of prophecies in the sacred texts of the preceding world religions. Baha'is hold all revealed scriptures in highest regard as the word of God, believing that the teachings of Baha'u'llah, by virtue of the fact that they are the most recent revelation from God, are the most relevant for today.

The many teachings revealed by Baha'u'llah cover every aspect of life and relations between humanity and creation. Among the most basic tenets is a belief in the unity and

interconnectedness of all things: the singularity of God; the equality of the races, sexes and all humanity; and that the chief task facing humanity is the construction of a just and merciful world-embracing civilization.

The pursuit of unity is reflected in the Faith's administrative order which includes elected local, regional, national and international administrative bodies. The worldwide headquarters of the Faith is located on Mount Carmel in Haifa, Israel – the final resting place of the remains of The Bab.

Baha'is believe unity should also characterize the relationship between humanity and the natural environment created by an all-powerful God. In the words of Baha'u'llah (1976: section CXXXII, 288), Ye are all the fruits of one tree, the leaves of one branch. From the Baha'i perspective, humanity is both physically and metaphorically linked to the world. In a letter, Shoghi Effendi (1933), a direct descendant of Baha'u'llah and known as the Guardian of the Baha'i Faith, wrote:

> We cannot segregate the human heart from the environment outside us and say that once one of these is reformed everything will be improved. Man is organic with the world. His inner life moulds the environment and is itself also deeply affected by it. The one acts upon the other and every abiding change in the life of man is the result of these mutual reactions.

Baha'is recognize that the world is undergoing rapid socio-economic transitions that make the protection of the environment and sustainable development both critical and challenging. Baha'is believe that only an integrated, balanced and comprehensive world view with a belief in a divine creator and unity of purpose will resolve environmental and development challenges. For example, when science and technology don't serve a divinely ordained purpose, they will actually contribute to the erosion of the planet's biodiversity. Materialistic civilization that replaces the idea of citizen' with consumer' cannot concern itself with the long-term viability of life on Earth.

THE INTERCONNECTEDNESS OF HUMANITY AND THE EARTH

The Baha'i view on environmental conservation and sustainable development holds that: (a) because the natural universe is a reflection of the majestic qualities and attributes of the Supreme Being, it inspires and should be accorded the utmost respect; (b) all of creation is interconnected, and (c) that the unity of humanity is the essential truth and compelling force in this age. Of this, Baha'u'llah (1976: section CXVII, 250) wrote: The Earth is but one county, and mankind its citizens. The concepts of world citizenship, prudent stewardship of the Earth, and the interconnectedness of all things is the essence of the Baha'i Faith.

Abdu'l Baha (1982) (translated as Servant of the Glory), the son of Baha'u'llah amplified this point:

> For every part of the universe is connected with every other part by ties that are very powerful and admit of no imbalance, nor any slackening whatever •••

In another reference, he remarked:

> Cooperation and reciprocity are essential properties which are inherent in the unified system of the world of existence, and without which the entire creation would be reduced to nothingness.
>
> (Abdu'l Baha, from a hitherto untranslated tablet)

At the very heart of the Baha'i view of the relationship between humanity and the natural universe is the belief that all of creation is an expression of the many names and attributes of an all-powerful God. Like the many different attributes of God, the natural realm has diverse causes or ideal environments in which it flourishes and expresses itself. Life is tenacious and can adapt itself to such diverse climates as polar, temperate, tropical and desert.

> Nature in its essence is the embodiment of my name, the maker, the creator. Its manifestations are diversified by varying causes, and in this diversity there are signs for men of discernment. Nature is God's will and is its expression in and through the contingent world.
>
> (Baha'u'llah, 1982)

> Every man of discernment, while walking upon the earth, feeleth indeed abashed, in as much as he is fully aware that the thing which is the source of his prosperity, his wealth, his might, his exaltation, his advancement and power is, as ordained by God, the very earth which is trodden beneath the feet of all men. There can be no doubt that whoever is cognizant of this truth, is cleansed and sanctified from all pride, arrogance, and vainglory.
>
> (Baha'u'llah, 1979)

Yet, while nature is seen as the repository of the many attributes of God, Baha'is are not pantheists, i.e., they do not worship nature or hold it in high esteem for its own sake. The natural realm exists to serve a humanity that has as its task the carrying forward of an ever-evolving divinely ordained world order that will usher in universal peace and harmony. As such, Baha'is believe that humanity must act as a wise steward of the natural realm, though neither nature nor humanity is at the core of the universal design. Rather, it is God.

THE ENVIRONMENTAL CHALLENGE AND SOLUTIONS

Just as humanity, the environment and spirituality are all interconnected, so too are the factors that have led to the environmental challenges. Speaking on behalf of the worldwide community of Baha'is, the BIC office at the UN issued a statement making the point:

> None of these problems – the debilitating inequities of development, the apocalyptic threats of atmospheric warming and

> ozone depletion, the oppression of women, the neglect of children and marginalized peoples, to name but a few – can be realistically addressed without considering all the others. None can be fully addressed without a magnitude of cooperation and coordination at all levels that far surpasses anything in humanity's collective experience.
>
> (Baha'i International Community, 1998a)

According to the BIC, the unfettered exploitation of planetary natural resources is one symptom of a sickness of the human spirit. Thus, any lasting solution to the environmental and developmental challenges will need to recognize the spiritual nature of each human, the interdependency of all humans, and their relationship with the environment. In other words, development will need to be more than simply for short-term economic advantage; it must also further and benefit the minds and spirits of all humanity.

Clearly, cooperation between all peoples, governments and agencies will be required to effect lasting solutions to the environmental challenges. However, the BIC points to certain trends in the world which tend to undermine the very foundations of collaboration. Among these it includes:

> ••• the widespread lack of moral discipline, the glorification of greed and material accumulation, the increasing breakdown of family and community, the rise of lawlessness and disorder, the ascendancy of racism and bigotry, and the priority given to national interests over the welfare of humanity – all of which destroy confidence and trust, the foundations of collaboration.
>
> (Baha'i International Community, 1997a)

It is the Baha'i position that only the abandonment of these destructive trends will create the necessary setting in which the spiritualization of humanity can be realized and the consequent unity and cooperation between humans can develop solutions to meet the environmental challenges.

> Such qualities include love, compassion, forbearance, trustworthiness, courage, humility, cooperation and willingness to sacrifice for the common good – qualities of an enlightened citizenry, able to construct a unified world civilization.
>
> (Baha'i International Community, 1997a)

THE NATURE OF SUSTAINABLE DEVELOPMENT

Development, in the Baha'i view, is an organic process in which the spiritual is expressed and carried out in the material (Abdu'l-Baha, 1995). As with the environmental challenge, the Baha'i view calls for broad-based organic answers that are consistent with the development of the spirituality of all people.

For example, community growth and development will need to respond to the genuine need of all people to have close contact with the natural world. This will influence all aspects of development – from design and engineering to community and land-use planning. Primary among these will be the need for carefully planned maintenance of agricultural lands.

Baha'is believe that science and technology can only provide answers to sustainable development when they take into account the needs of the human soul. For example, there is little value in building high-efficiency vast networks of concrete urban roads if the style of architecture blocks sunlight, prevents people from walking and generally leaves the human being dwarfed.

> The vast forces of science and technology must be harnessed to serve the material, intellectual, emotional and spiritual needs of the entire human family. This will require that all peoples be involved in generating scientific knowledge and determining its applications. As participation increases, technologies which have tended to desensitize and alienate, to make satisfying work and crafts redundant, to destroy the environment, and to cause sickness, infirmity or death, will, no doubt, be reconsidered, redesigned or abandoned.
>
> (Baha'i International Community, 1997b)

Stewardship, from a Baha'i point of view means that the value of nature and its preservation cannot be expressed in sheer economic terms. A more balanced approach to sustainable development can only result when planners have a deep understanding of the significance of the natural realm in the material and spiritual development of all humanity.

Consequently, good stewardship and prudent management of the Earth's resources is not merely an *add-on* that is developed in response to a paucity of the resources, but rather an essential and fundamental responsibility that must be given fullest consideration at all times. Good stewardship doesn't involve rescuing nature from environmental disasters. It involves long-term planning that minimizes any possibilities of such emergencies occurring.

Material development which serves solely an economic master is not a model favored by the Baha'is. They believe that the diverse peoples of the world will be more inclined to support development policies and programs if they are based on spiritual principles and the inherent dignity of the human being. As such, Baha'is have proposed that spiritual indicators be applied to measure the value of development in terms of its impact on the spiritual, cultural and social advancement of humanity.

These indicators are drawn from the essential teachings of Baha'u'llah. For example, one of the main tenets of the Baha'i Faith is that men and women are equal. Baha'is believe that just and sustainable development will only be possible when women worldwide are welcomed as equal co-partners in every field of endeavor.

> For Baha'is, the commitment to the emancipation of women is not a recent development nor is equality of the sexes a vague ideal. It is our conviction that the unification of the human race depends on the establishment of the equality of men and women.
>
> (Baha'i International Community, 1998b)

Another of the Baha'i development indicators concerns the equitable distribution of wealth. One of the basic tenets of the Baha'i Faith is the need to redress the extremes of wealth and poverty whereby absolute impoverishment and lavish luxury are virtually side by side. Experts tells us that there are enough resources in the world to meet the needs of all humanity. Therefore, to eliminate poverty, we will need to find more equitable methods of distribution and we will need to moderate excessive and sometimes wasteful consumption and the accumulation of wealth for its own sake. At the same time, nations will need to develop fair and equitable trade relations built on the principle that the trading partners are true equals.

If development is to be sustainable, the Baha'is suggest the following:

> Wealth is most commendable, provided the entire population is wealthy. If, however, a few have inordinate riches while the rest are impoverished, and no fruit or benefit accrues from that wealth, then it is only a liability to its possessor. If, on the other hand, it is expended for the promotion of knowledge, the founding of elementary and other schools, the encouragement of art and industry, the training of orphans and the poor – in brief, if it is dedicated to the welfare of society – its possessor will stand out before God and man as the most excellent of all who live on Earth and will be accounted as one of the people of paradise.
>
> (Abdu'l Baha, 1990)

Universal education is one of the requirements that will speed the advent of a world united to promote common cause. Education that promotes a world consciousness and the understanding that there is an integral connection between every human being will create the conditions in which humanity is united to meet environmental and developmental challenges.

Unity is a prerequisite for any effort to safeguard the Earth's habitat. The type of unity envisioned by the Baha'is encompasses much more than just geography, climatology or biology. Rather, it is the outgrowth of an undying belief that humanity is a one world community. In such a community, it seems only logical that matters of economic relations and sustainable development must be addressed with a balanced universal perspective that takes into account the world's many cultures and resources.

PROPOSED COURSES OF ACTION

Calling on principles enunciated in the revelation of Baha'u'llah, whom Baha'is regard as the messenger and prophet from God for this age of humanity, the Baha'is of the world have proposed specific courses of action that will protect the environment and define the parameters of sustainable development. Over 100 years ago, Baha'u'llah called for an international legal system, sharing of the world's resources, a realignment of the world's economic and governmental relations, and reform in the behavior and patterns of human consumption.

Drawing on these teachings, the BIC prepared a statement for the proposed Earth Charter for the United Nations Conference on Environment and Development (UNCED) in 1992. In the document, the Baha'is outlined the process for achieving universally acceptable standards:

> It is our conviction that any call to global action for environment and development must be rooted in universally accepted values and principles. Similarly, the search for solutions to the world's grave environmental and developmental problems must go beyond technical–utilitarian proposals and address the underlying causes of the crisis. Genuine solutions, in the Baha'i view, will require a globally accepted vision for the future, based on unity and willing cooperation among the nations, races, creeds, and classes of the human family. Commitment to a higher moral standard, equality between the sexes, and the development of consultative skills for the effective functioning of groups at all levels of society will be essential.
>
> (Baha'i International Community, 1997c)

The document proposed that representatives of the world's religions be assembled, possibly under the auspices of the World Bank or the UN Development Programme, to consult about spiritual principles and their impact on both the individual and the progress of society (Baha'i International Community, 1998a). Such an assemblage, the Baha'is believe, could reach common agreement on a limited number of spiritual principles and how these would provide a basis for developing policy priorities. Based on this agreement, goals and benchmarks for progress would be established and monitored by the organization under whose auspices the assemblage is convened.

The Baha'is believe that the world religions can take the initiative and collaborate because of the common thread that unites all of the world's major religious traditions.

> The changes required to reorient the world toward a sustainable future imply degrees of sacrifice, social integration, selfless action, and unity of purpose rarely achieved in human history. These qualities have reached their highest degree of development through the power of religion. Therefore, the world's religious communities have a major role to play in inspiring these qualities in their members, releasing latent capacities of the human spirit and empowering individuals to act on behalf of the planet, its peoples, and future generations.
>
> (Baha'i International Community, 1997c)

Furthermore, the cooperation of an international development agency would signal their recognition of the significance of the spiritual dimension of human nature. Already the internationally accepted Agenda 21 and The Habitat Agenda have acknowledged that the spiritual needs of the individual and of society are significant factors in human progress and are inseparable from ecological, economic, social, and cultural development.

The next step would involve the development of consultative processes on both the national and local

levels whereby communities would be encouraged to utilize and develop their own independent spiritual measures for action, derived from the larger plan. Such plans and policies would likely have the backing of many and would receive the formalized support of religious authorities and institutions.

In a reflection of the Baha'i administrative order, which has no clergy but devolves responsibility on each individual right down to the local community, the Faith stresses the importance of local action in any initiatives.

> Development must be decentralized in order to involve communities in formulating and implementing the decisions and programs that affect their lives. Such a decentralization need not conflict with a global system and strategy, but would in fact ensure that developmental processes are adapted to the planet's rich cultural, geographic, and ecological diversity.
>
> (Baha'i International Community, 1997c)

Baha'is believe that the individual has a key role in the unfolding of a planetary system of sustainable development. Therefore, acknowledging the spiritual dimension of humanity and providing for the moral, emotional, physical and intellectual development and education of each person will be a building block toward a new vision of planetary society.

To meet the environmental and development challenges, Baha'is affirm that the top-down model of community development will need to give way to a more participatory, knowledge-based and values-driven process of governance. When people view the decision-making process as something they own – not as a remote and Byzantine system of laws – they will accept their responsibility for shaping a new world.

At the very core of the environmental and developmental crises facing humanity, Baha'is believe, there is a lack of moral leadership that pervades every level of decision making – from the highest levels of government to the family unit itself. This is evidenced by the constant discovery of political scandals that reveal a bankruptcy of ethical leadership. Humanity may have even lost its ability to define and identify morality in leadership because of the barrage of messages that obfuscate and confuse the issue.

While the world's religions, development organizations, governments and individuals are all called upon to play a role in sustainable development, long-term solutions will require a new and integrated vision of global society. This vision will have as its underpinnings and its charter, a new set of values based on the belief that all of humanity is one. For Baha'is, the very bedrock and hope for a sustainable new world order is the acceptance of the oneness of humanity. This principle will cause the restructuring of the world's administration to reflect the fact that the world is one nation. This does not mean that any culture or nation must abandon its distinctive identity. In fact, the entire principle of unity in diversity, which the Baha'i Faith champions, supports and actively encourages each people's right to maintain, protect and uphold its distinctiveness in the face of the homogenizing influences of international capital.

In the Baha'i view, world unity is not mutually exclusive of cultural diversity and national autonomy. Each person can legitimately have a balanced sense of pride in his or her culture and national identity. However, every person is called to a broader notion of loyalty: the uplifting and progress of the human soul, of every human being and the entire world civilization. The Baha'i approach emphasizes that the world is one nation and it calls for a universal auxiliary language, which may in the future prove to be English. The yet to be determined auxiliary language will facilitate inter-cultural communication and will not replace peoples' own mother tongues. Each individual maintains the right to preserve his or her cultural identity and mother tongue.

> In the view of the BIC, acceptance of the oneness of humanity is the first fundamental prerequisite for this reorganization and administration of the world as one country, the home of humankind. Recognition of this principle does not imply abandonment of legitimate loyalties, the suppression of cultural diversity, or the abolition of national autonomy. It calls for a wider loyalty, for a far higher aspiration than has so far animated human efforts. It clearly requires the subordination of national impulses and interests to the imperative claims of a unified world. It is inconsistent not only with any attempt to impose uniformity, but with any tendency towards excessive centralization. Its goal is well captured in the concept of unity in diversity.
>
> (Baha'i International Community, 1997d)

The BIC believes that the change in consciousness that would be represented by the adoption of the term *world citizenship* is a prerequisite before the peoples of the planet can accept and promote a coordinated and reasonable approach to global sustainable development. The entire idea of world citizenship can only take hold when one accepts the inter-relatedness of all human beings, of the impact of their actions upon each other. It means that the world is no longer constituted of billions of discrete beings and scores of disconnected governments and trans-national corporations. With the advent of world citizenship, each accepts that his or her actions in any part of the globe is likely to have impacts well beyond the local or regional spheres of influence.

The Baha'i understanding of the implications of world citizenship extends beyond simply a new passport or slogan:

> World citizenship encompasses the principles of social and economic justice, both within and between nations; non-adversarial decision making at all levels of society; equality of the sexes; racial, ethnic, national and religious harmony; and the willingness to sacrifice for the common good.
>
> (Baha'i International Community, 1997e)

The BIC believes that the most effective method for promoting sustainable development is logically through adoption of world citizenship. The full meaning and import of world citizenship will have an impact on the way nations conduct themselves with each other. When humanity and its economic, social, and political orders are preoccupied with disunity, antagonism and rigid provincialism, the Baha'is submit that there is no room for a concerted worldwide strategy on sustainable development. In other words, any effort to realize sustainable development can only be marginally successful without the animating principles of world citizenship and one-world homeland. The prerequisites clearly call for harmony and unity amongst all peoples and nations of the world.

In a paper entitled *World Citizenship: a Global Ethic for Sustainable Development*, presented to the first session of the UN Commission on Sustainable Development, 14–25 June 1993, the BIC reflected at length on the necessary first step of establishing the concept of world citizenship. They went so far as to lay out a plan for its introduction and the requisite actions of the world leaders.

> They should foster an ethic of service to the common good and convey an understanding of both the rights and the responsibilities of world citizenship.
>
> Using the concept of world citizenship as an integrating theme, the UN should publicize its ideals, activities and goals, so that people come to understand the unique and vital role the UN plays in the world and, therefore, in their lives. Similarly, the UN should promote world citizenship in all its public activities, including celebrations of its historical milestones and tours of UN headquarters. Every UN document that deals with sustainable development should also include this principle—beginning with the preamble of the proposed Earth Charter. World citizenship must become the single most important point of ethical reference in all UN activities.
>
> The services of the advertising industry should be enlisted to promote world citizenship.
>
> (Baha'i International Community, 1997e)

THE PROMISE OF A BETTER FUTURE

The Baha'is believe that there are dual processes at work in the world: the one best characterized as spiritualizing, embryonic, and beneficial to humanity; the other is the decaying and destruction of institutions and ways of thinking that no longer serve an evolving worldwide civilization.

The Baha'is are optimistic that humanity will survive the serious environment challenges and development issues facing it. They believe that the covenant God made with Abraham and Noah and has renewed with every Messenger sent to humanity is evidence of the long-term viability of humanity. This does not, however, allow humanity to abdicate its stewardship responsibilities nor the huge commitment to persevere and make sacrifices and changes that will transform the world. Shoghi Effendi (1980) looked forward to this renewal of civilization:

> In such a world society ••• [t]he economic resources of the world will be organized, its sources of raw materials will be tapped and fully utilized, its markets will be coordinated and developed, and the distribution of its products will be equitably regulated ••• The enormous energy dissipated and wasted on war, whether economic or political, will be consecrated to such ends as will extend the range of human inventions and technical development, to the increase of the productivity of mankind, to the extermination of disease, to the extension of scientific research, to the raising of the standard of physical health, to the sharpening and refinement of the human brain, to the exploitation of the unused and unsuspected resources of the planet, to the prolongation of human life and to the furtherance of any other agency that can stimulate the intellectual, the moral and spiritual life of the entire human race.

According to the BIC, it is the actions of governments, non-governmental organizations, the forces of capital, society in general, and significant individuals that will determine how quickly humanity arrives at a universal consensus for sustainable development. The onus is on every party to consciously and deliberately give a thorough evaluation to the meaning of the goals toward which they are working. This will ensure that all parties can be effective partners in progress. The BIC says that "clear goals, meaningful policies and standards, identified programs, and agreed upon indicators of progress are necessary if advancement toward humanity's common future is to be charted and regular corrections to that course determined and carried out" (Baha'i International Community, 1998a).

BAHA'I ACTION ON SUSTAINABLE DEVELOPMENT

Representing the world's Baha'is, the BIC office at the UN has played a prominent role in the various UN-sponsored summits on the environment and sustainable development. Exemplary among these, was the participation of the BIC in the Earth Summit—the Rio de Janeiro Conference in June 1992.

The Baha'is focused on the Earth Charter (*see* **Earth Charter**, Volume 5) which they felt was potentially the most significant document under consideration at Rio de Janeiro. In numerous languages they circulated nearly one million copies of the environmental and development statements of the BIC. In the opening paragraph of its presentation to a preparatory working group of the UNCED, the BIC wrote of the Charter:

> It could offer a unifying vision for the future and articulate the values upon which a peaceful, prosperous and harmonious world society could practically be constructed. In so doing, the Earth Charter could lift the context of deliberations on humanity's future to a new level—to the level of principle. Only discourse at the level of principle has the power to invoke a moral commitment, which will, in turn, make possible the discovery of enduring solutions to the many challenges confronting a rapidly integrating human society ••• the Earth

> Charter can tap a powerful source of individual and collective motivation, which will be essential for the reorientation of the world toward a sustainable future.
>
> (Baha'i International Community, 1997f)

The Baha'i presentation to UNCED urged that the idea of the oneness of humanity should be proclaimed in the preamble to the Charter, which should then be taught in the world's schools and communicated worldwide in preparation for the organic change in the structure of society which it implies (Baha'i International Community, 1997f).

In fact, the landmark Peace Monument unveiled at the conclusion of the 1992 Earth Summit in Rio de Janeiro was an initiative of the BIC. At the Summit's closing ceremony, soil from some 40 nations was deposited by children into the 5-m high monument. Each year since the Summit, World Environment Day in Rio includes a ceremony at the monument during which soil from other nations is added. The inscription on the monument is the words of Baha'u'llah: The Earth is but one country, and mankind its citizens.

Both Baha'i communities and individual Baha'is are in the forefront of activities aimed at furthering conservation and sustainable development. The following list is a small sample of projects Baha'is are involved with worldwide:

1. The establishment of a Baha'i office of the environment as an adjunct of the BIC office at the UN.
2. Issuing a 1989 compilation of Baha'i writings – *Conservation of the Earth's Resources*. The text has been studied by Baha'i communities worldwide.
3. Numerous national and local Baha'i communities have established their own environmental offices and committees, often in cooperation with like-minded organizations. In Japan, Canada, Brazil, Taiwan, Colombia, the Philippines and other nations, Baha'i communities have established curricula for education about the environment.
4. Nur University in Santa Cruz, Bolivia, an institution of higher learning, established on Baha'i principles, offers a Masters degree in Development.
5. A range of publications dealing with environmental and developmental issues is now published by Baha'is. This includes: *One Country*, a quarterly newsletter of the BIC; *Ecologia Y Unidad Mundial*, an Argentine Baha'i newspaper; and others.
6. The Baha'i Vocational Institute for Rural Women, located in India and the Clean and Beautiful Swaziland campaign founded by a Baha'i – Dr Irma Allen – have both received Global 500 Awards from the UN Environment Programme.
7. An organic farming project by the Baha'i community of Japan teaches how to grow food without artificial fertilizers or pesticides.
8. In rural Kenya, a Baha'i-sponsored development project encourages and empowers village women to develop their own entrepreneurial weaving businesses.
9. In Bolivia and Malaysia, Baha'i communities have launched fish farming projects.
10. Baha'is in the UK, the Philippines, Singapore and Taiwan have all organized and/or sponsored arts and educational activities geared to creating awareness of the fragile environment and conservation.
11. Local Baha'i communities in the UK have become active proponents of Local Agenda 21, working with partner groups and with local authorities.
12. Working in collaboration with other organizations, the BIC hosted two World Forestry Charter Gatherings in 1989 and 1994.
13. The BIC made a formal presentation to the World Faiths and Development Dialogue hosted by the President of the World Bank and the Archbishop of Canterbury at Lambeth Palace during the Lambeth Conference, February 1998.

Finally, as if to address directly the very issue of environmental biodiversity and sustainable growth, the architecture and landscaping of each of the Baha'i Holy Sites around the world is a model of the blending of natural and architectural beauty, efficiency and diversity. Each of these sites features a diverse range of flora to reflect the Faith's teachings about diversity and the buildings are designed to complement and augment their surroundings.

BAT (Best Available Technology)

The term BAT has undergone a significant change in meaning since its introduction into environmental policy debates in the early 1970s. Initially, BAT meant regulation through a technological standard, under which the relevant government agency requires firms to employ the pollution control or abatement technology that yields the lowest level of pollution. The US Clean Air and Clear Water Acts also instructed regulators to consider feasibility and cost factors; BAT was interpreted to mean designating of the most effective currently demonstrated and cost-effective technology. These trade-offs were highlighted in various elaborations, including BAT economically achievable, BAT not entailing excessive costs, best available demonstrated technology, and best practicable technology. The actual practice of regulation by technological standard was soon criticized on two grounds. By the mid-1970s, it was widely viewed as having the effect of stalling or even freezing the introduction of new technology; though requiring use of particular technology created a stable base level of environmental protection, it also inhibited further progress by discouraging innovation. In the 1980s, critics contended that actual technological standards were emphasizing end-of-pipe treatment rather than pollution prevention. Greater acceptance of economists' arguments that market incentives would yield more pollution control at less overall cost, and environmentalists' arguments for preventing or minimizing pollution through redesign of goods and industrial processes produced a very different policy debate in the early 1990s. BAT came to mean the production technology yielding the greatest reduction in pollution rather than a regulatory approach.

M J PETERSON *USA*

Bateson, Gregory

(1904- 1980)

Gregory Bateson was a British anthropologist, trained at St. John's College, who built his career in the US, and who also made significant and innovative contributions in the fields of communication, cybernetics, information, psychiatry and learning theory. He was the son of geneticist William Bateson who is regarded as the founder of the field of genetics, and grandson of William Henry Bateson, who had been a master at St. John's College where he brought about significant reforms. Gregory was first married to Margaret Mead with whom he pioneered the use of visual methods in ethnographic research in Bali (Lipset, 1980). They were parents of Mary Catherine Bateson, an anthropologist and contemporary author who collaborated with him and who carries on some elements of his work.

Beginning with the publication of the ethnography *Naven* in 1936 (Bateson, 1958), a consistent underlying theme in all of Bateson's work was a concern with science as a *process* of knowing rather than an accumulation of facts, and with the social implications of errors in scientific thought that occur as a result of what Whitehead referred to as the fallacy of misplaced concreteness, or that of regarding scientific explanation as a description of external and concrete phenomena, rather than as a product of interaction between the observer and that which is observed. A second fallacy he observed was that of seeking to control an interactive system of which one is a part, through quantitative measurement. An example of these types of errors is found in the characterization of ecosystems at a single level of analysis, as composed of discrete entities that respond mechanically to inputs and outputs of energy. According to Bateson, reliance on this type of analysis would only increase the likelihood of runaway ecological degradation, because the false sense of an ability to predict and control the factors of interest would only make a pathological system more efficiently pathological. This would lead to more rapid self-destruction, since it does not address the false premises upon which the model is based. Organizing society and technology around this false sense of control would also reduce flexibility and thus the capacity to respond to ecological degradation (Bateson, 1979; Harries-Jones, 1995). The most famous example of this in Bateson's work is the alcoholic who attempts to assert his mastery over his drinking problem by resorting to a stiff drink to bolster himself.

Instead, Bateson stressed the importance of relationships that provide the basis for organization, and that are a greater limiting factor than energy. Relationships, which are sustained through communication of information rather

than by energy flows, are also important as a source of information about context and meaning. Recursive relationships in turn lead to pattern, which cannot be characterized through linear logic and quantitative analysis, which are therefore inadequate for characterizing living systems. An example of this error is found in Darwinian theories of evolution, in which evolution is characterized as a linear process and a force of progress, which fails to account for organization and denies interdependent relationships among organisms and their environment (Bateson, 1979; Harries-Jones, 1995).

Another important contribution was his concept of the double-bind, a paradoxical and incoherent situation in which contradictory rules appear simultaneously relevant, such as when a child receives conflicting cues from a parent, or in which a playful situation is understood literally. In other words, given that meaning changes with context, behavior is constrained by a perceived context or definition of a relationship that is no longer relevant, which leads to nonsensical beliefs. Context is taken to include relationships as well as fundamental premises and habitual behaviors that are seldom questioned, all of which constrain action, and that are normally taken as a given. In clusters, such beliefs have been linked to schizophrenia as well as to forms of common madness (Bateson, 1979; Jaeger, 1994). Associated with this is the concept of deutero- or double-loop learning, which refers to learning about context which, in contrast with rote-learning, provides a frame of reference and meaning to a given situation. Papers addressing these and related concepts were brought together and published in his best-known book, *Steps to an Ecology of Mind* (Bateson, 1972).

Bateson alluded a number of times to a new unnamed science, for which, in his final book, *Mind and Nature* (Bateson, 1979) he offered a set of epistemological principles. In sum, he is widely regarded as having provided a new perspective on the ecological predicament. In retrospect, many of his ideas can be found embedded in the concepts of post-normal science and adaptive management of ecosystems (Tognetti, 1999).

Brent Spar

The public protest against the dumping of an oil-contaminated derelict off-shore petroleum platform was a watershed in the clout of non-government organizations. Transnational giant, Royal Dutch Shell, backed down in the face of massive public outrage organized by Greenpeace.

The Brent Spar, a 4000-tonne oil installation, was to be towed from the North Sea and dumped in the North Atlantic, pursuant to a permit issued by the government of the UK on February 16th, 1995. Greenpeace launched protests in May, 1995 including the occupation of the rig off-shore by scientists and others. Greenpeace argued that dumping a rig at sea would set a dangerous precedent and would undo the progress against ocean dumping. North Sea environment ministers were to meet in June in Denmark on the issue of ocean discharges of hazardous substances within the Oslo and Paris Commission (OSPARCOM). The Brent Spar issue caught fire in a dramatic way as Greenpeace catalyzed a massive public outcry against Shell. Shell, its reputation already severely damaged by allegations of environmental and human rights abuses in the Niger Delta, initially rejected its critics' complaints. It had never backed down in the face of public protest, even in the high-profile and international controversy that followed the death of author and Shell critic Ken Saro-Wiwa at the hands of Nigerian dictator General Abacha.

But the growing momentum in the movement opposed to dumping the Brent Spar increased. By June, Shell reversed itself and, although the towing of the installation was already underway, announced it would not dump the Brent Spar at sea but would tow it into a Norwegian fjord, where it remains today. Subsequently, the controversy is remembered as one of exaggerated claims about the degree of contamination of the oil installation by Greenpeace, which has admitted its estimates subsequently proved false. Greenpeace, however, maintains that despite its errors, the precedent against ocean dumping of oil installations was important and one which was subsequently endorsed by 11 of the 13 North Sea nations within OSPARCOM.

Brower, David

(1912- 2000)

David Brower was one of North America's leading environmentalists. Over his extremely active life, he founded and steered some of the world's most influential environmental organizations. In all things, he was supported by Anne Brower, his equally ecologically aware wife.

An accomplished climber and ski mountaineer enthusiast, David Brower joined the Sierra Club in 1933, and was elected to its national board in 1941 (*see* Sierra Club, Volume 5). He became the organization's first executive director in 1952, a position he held until 1969. Under his leadership the organization grew from 2000 to 77 000 members. In 1969, he left the club staff on request. Despite a number of policy differences, Brower continued to be perennially elected to the Sierra Club Board (in 1983, 1986, 1995 and 1998), resigning in 2000 complaining that the organization lacked a sense of urgency in its campaigns. He died 6 months later.

In 1969, Brower turned his attention to the creation of a grassroots, activist organization, Friends of the Earth (FoE) (*see* Friends of the Earth, Volume 5). Brower realized his vision of a truly global organization with member groups in 63 countries. But, once again, as executive director of FoE (US), he experienced conflict with the board of directors. Brower believed FoE should pursue nuclear disarmament. The culminating issue was the board directive to relocate national headquarters from San Francisco to Washington, DC. Brower's intransigence led to his termination in 1982. When Brower went to court to challenge the FoE Board's action, the news made the front page of the *New York Times*.

In 1982, Brower founded Earth Island Institute as well as the biennial Fate and Hope of the Earth Conferences, working to integrate peace, environmental, human rights and social justice groups. His biography, *Encounters with the Archdruid* by John McPhee, is in its 27th printing.

Brower is best remembered for his successful campaigns to keep dams out of Dinosaur National Monument, the Yukon and the Grand Canyon. He also played a significant role in the creation of national parks and seashores in Kings Canyon, the Redwoods, the North Cascades, Alaska and Cape Cod, among many others.

ELIZABETH MAY *Canada*

Buddhism and Ecology

Stephanie Kaza
University of Vermont, Burlington, USA

During its 2500 year history, Buddhism has evolved across a wide range of physical and cultural geographies. From the Theravada traditions in tropical South and Southeast Asia, to the Mahayana schools in temperate and climatically diverse China and Japan, to the Vajrayana lineages in mountainous Tibet, the Buddhist teachings have been received, modi ed, and elaborated in many ecological contexts. Across this history, Buddhist understandings about nature and human-nature relations have been based on different teachings, texts, and cultural views. These have not been consistent by any means; in fact, some views directly contradict each other.

Scholars debate whether or not Buddhist philosophies of nature led to any recognizable ecological awareness among early Buddhists. Most members of early Buddhist societies, including many monks, preferred the comforts of village life over the threats of the wild. Only forest ascetics chose the hermitage path with its immersion in wild nature. The word (nature) itself has many different meanings in various Asian languages. Concepts and attitudes towards nature vary across time and place as well. Indian Buddhist literature, for example, shows relatively little respect for wild nature, preferring tamed nature instead; Japanese Buddhism reveres the wild but engages it symbolically through highly developed art forms.

Even with these distinctions, Buddhist texts do contain many references to the natural world, both as inspiration for teachings and as a source for ethical behavior. For those exploring Buddhist teachings in the context of the environmental crisis, Buddhist traditions are potential sources for philosophical and behavioral guidelines towards nature. From the earliest guidelines for forest monks to

the hermitage songs of Milarepa, from the Jataka tales of compassion to Zen teachings on mountains and rivers, the inheritance is rich and diverse.

EARLY BUDDHIST VIEWS OF NATURE

Buddhism developed as a major world religion in the 5th century before the common era (BCE) in north India, where the historical Buddha lived and taught. At the time, the region was undergoing ecological upheaval through the growth of urban centers and political centralization. Previously uninhabited forests were cleared for agricultural expansion and town development. Wild areas that were home to rhinos, elephants, tigers, and large snakes, were seen as lled with threat but also available as marginal land. The Buddha and his followers took advantage of some of these lands but adapted their teaching and retreat times to accommodate the farming seasons and to draw on local community support.

In the canonical story of the Buddha, there are many references to nature, especially trees. The Buddha to be, Siddharta, was born the son of a king of the Shakya tribe in the foothills of the Himalayas. His birth took place under a tree, and as a young man, Siddharta spent many years wandering in the forests and mountains of India in pursuit of spiritual understanding. At the time of his enlightenment, he had been sitting at the foot of a large bodhi tree (*Ficus religiosa*) for seven days. According to the story, the Buddha vowed not to move from the tree until he gained some understanding of the source of human suffering. For many years after, he taught in shaded groves to large gatherings of monks and lay people.

After six days and nights of sitting in meditation, in a state of great concentration, he perceived all his previous lives in a continuous cycle of birth and death, and then saw the vast universe of birth and death for all beings. From this he came to understand the law of cause and effect or *karma* and the universal existence of suffering due to impermanence. This was the First Noble Truth. Then he realized the driving force behind birth and death, craving or attachment to existence: the Second Noble Truth. As the Buddha saw that all phenomena, i.e., all of nature, arise from complex sets of causes and conditions, he realized that liberation from suffering lay in this very insight: the law of mutual causality or dependent origination (in Sanskrit *pratityasamutpada*, in Pali *paticca samuppada*). This was the Third Noble Truth: the path to release from suffering. He further laid out a prescription for practice in the Fourth Noble Truth of the Eight-fold Path. He named right livelihood, right practice, and right speech, among others, as methods for achieving release from suffering.

The Buddha s profound appreciation for the universal existence of suffering engendered in him a lifetime compassionate response, expressed in the form of sharing his teachings with others. He saw that compassion (*karuna*) and loving kindness (*metta*) for all beings arises directly from this understanding of the nature of suffering. Early Buddhism was strongly in uenced by the Hindu and Jain principle of *ahimsa* or non-harming. Buddhist teachings urged monks not to harm any living thing; killing animals for food was against the monastic code. The classic Jataka Tales of India recount the many former lives of the Buddha as an animal or tree when he showed great compassion to others who were suffering. Over 500 tales have been handed down from the oral tradition, ranging from simple animal fables to fragments of heroic epics. It is said that the verses and stories were told by the Buddha himself as a way of commenting on particular life situations challenging his students. In each of the tales, the Buddha-to-be sets a strong moral example of compassion for plants and animals in his many lifetimes before his rebirth as the Buddha (Beswick, 1956).

The Agganna Sutta from the Pali Canon collection of early Buddhist texts relates the Buddhist counterpart of a creation story in which human activities clearly affect their environment. The original beings are described as self-luminous, subsisting on bliss and freely traveling through space. At that time it is said that the earth was covered with a avorful substance much like butter from which greed originated. The more butter that the beings ate, the more solid their bodies became. Difference of form appeared and the more beautiful ones developed conceit and looked down on the others. Self-growing rice appeared on the earth to replace the butter and before long, people began hoarding and then stealing food. As people erred in their ways, the richness of the earth declined. The point of the sutta is to show that environmental health is bound up with human morality (Ryan, 1998). Other suttas also spell out the environmental impacts of greed, hate, and ignorance, showing how these three poisons produce both internal and external pollution. In contrast, the practice of generosity, compassion, and wisdom can reverse such environmental decline and produce health and purity.

The early monastic code, the *Vinaya*, contained a number of guidelines for caring for the environment (De Silva, 2000). Monks were not to travel during the rainy season for fear of killing the worms and insects that come to the surface in wet weather. Similarly, monks were not to dig in the ground or drink unstrained water. Even wild animals were to be treated with kindness. Plants too were not to be injured carelessly but respected for all they give to people. Buddhists adopted a reverential attitude toward large trees, carrying on the Indian tradition regarding *vanaspati* or *lords of the forest*. Some of these huge trees were thought to be former Buddhas; protecting trees and preserving open lands were considered meritorious deeds. The Buddha constantly urged his followers to choose natural habitats to engage

in meditation, free from the influence of everyday human activity.

NORTHERN VIEWS

As Indian Buddhism developed into many strands of philosophy and practice, teachings were carried north to China. Each sect emphasized particular texts, principles, and practices, each with varying degrees of application to environmental concerns. The Hua Yen school of Buddhism, which arose in 7th century in China, placed particular emphasis on the law of interdependence or mutual causality. Ecological understanding of natural systems fits very well within the Buddhist description of interdependence (Cook, 1989). Throughout many cultural forms of Buddhism, nature is perceived as relational, each phenomenon dependent on a multitude of causes and conditions. These causes include not only physical and biological factors but also historical and cultural factors, i.e., human thought forms and values.

The Hua Yen Avatamsaka or Flower Ornament Sutra used a teaching metaphor, the Jewel Net of Indra, to communicate the infinite complexity of the multi-causal universe. This cosmic net contains a multifaceted jewel at each of its nodes, with each jewel reflecting all the others. If any of the jewels becomes cloudy (toxic or polluted), the less clearly it reflects the others. To extend the metaphor, stresses on any of the net lines, e.g., through loss of species or habitat, affect all the other lines. Likewise, if clouded jewels are cleared up (rivers cleaned, wetlands restored), life across the net is enhanced. Because the net of interdependence includes not only the actions of all beings but also their thoughts, the intention of the actor becomes a critical factor in determining what happens. This, then, provides both a principle of explanation for the way things are, and a path for positive action.

The law of interdependence suggests a powerful corollary, sometimes noted as emptiness of separate self. If all phenomena are dependent on interacting causes and conditions, nothing exists by itself, autonomous and self-supporting. This Buddhist understanding (and experience) of self directly contradicts the traditional Western sense of self as a discrete individual. Philosopher Alan Watts called this assumption of separateness the skin encapsulated ego, the very delusion that Buddhist practices seek to cut through. Interpreting the Hua Yen metaphor, modern American poet Gary Snyder suggests the empty nature of self provides a link to the wild mind, or access to the forces that determine the nature of life (Snyder, 1995). These forces act outside of human influence, setting the historical, ecological, and even cosmological context for life.

Tien-t'ai monks in 8th century China believed in a universal Buddha nature that dwelled in all forms of life. Sentient (animal) and non-sentient (plant) beings and even the earth itself were seen as capable of achieving enlightenment. This concept of Buddha nature is closely related to Chinese views of *chi* or moving energy that is ever changing, always taking on new forms. Thus their views of nature reflect a dynamic sense of flow and interconnection between all beings, with Buddha nature arising and transforming constantly.

Northern or Mahayana schools also came to emphasize the path of the *bodhisattva*, one who vows to serve others until all the world's suffering is extinguished. Where earlier Theravada schools emphasized achieving enlightenment and leaving the world of suffering, the northern schools influenced by Confucian social codes, placed great value on service to others. Tibetan schools reinforced this vow by encouraging people to treat all sentient beings as possibly having been their mother in a former life. Bodhisattva acts of service are thus personally motivated, creating a foundation for a kind of virtue ethic. This directly applies to relations with plants and animals as well as people, encouraging environmental protection and kindness as important to enlightenment.

As Zen Buddhism became established in Japan, monastic temples were often built in mountainous or forested places. The strong tradition of *haiku* and other classic verse forms cultivated a sense of oneness with nature, from insects to landforms. Dogen (1200–1253), founder of the Soto sect of Zen, spoke of mountains and waters as *sutras* themselves, the very evidence of the Dharma arising (Dogen, 1986). He taught a method of direct knowing, experiencing the dharma of nature with no separation. The goal of meditation was non-dualistic understanding, complete communion or transmission between two beings. Dogen showed how much of human suffering described in the First Noble Truth generates from egoistic views based in dualistic understanding. Enlightenment is then the breakthrough or liberation from these views to experience the self and myriad beings as one interpenetrating whole.

MODERN BUDDHIST ECOLOGICAL VIEWS

Buddhist environmental teachers and writers at the beginning of the 21st century emphasize five primary arenas of practice and philosophy which support an environmental view: interdependence, compassion, mindfulness, non-dualistic views, and detachment from self (Kaza and Kraft, 2000). At the heart of the Buddha's path is reflective inquiry into the nature of reality. Some people experience interdependence in its more ecstatic forms of communion with plants and animals or sacred places. But engaging interdependence in today's environmental context also means undertaking rigorous examination of conditioned beliefs and thought patterns regarding the natural world. This would include such challenges as objectification of plants and animals, stereotyping of environmentalists, dualistic

thinking of enemyism, the impacts of materialism, and environmental racism.

The law of interdependence is based on an understanding of the nature of the many relations at play in a situation. This could mean, for example, assessing who's who in an environmental conflict from a context of historical and geographical causes and conditions. Such investigation includes learning about ecological relationships under siege as well as observing the distribution of power across human political relationships.

The practice of *ahimsa* or *non-harming* arises from a true experience of compassion. Buddhist precepts or ethical guidelines are based fundamentally on reducing the suffering of others. The first precept, *not killing*, has been applied to environmental dilemmas related to food, land use, pesticides, pollution, and cultural economic invasion. The second precept, *not stealing*, suggests examining the implications of global trade and corporate exploitation of resources. *Not lying* brings up issues in advertising and consumerism. *Not engaging in abusive relations* covers a broad realm of cruelty and disrespect for non-human others. Vietnamese Zen teacher Thich Nhat Hanh interprets the precept prohibiting drugs and alcohol to include the toxic addictions of television, video games, and junk magazines. Non-harming extends to all beings, not merely to those who are useful or irritating to humans. It has also been applied to environmental oppression of plants, animals, rivers, rocks, and mountains as well as to human oppression based on race, class, or gender discrimination. This Green Buddhist teaching is congruent with many schools of ecophilosophy, which respect the intrinsic value and capacity for experience of each being.

Mindfulness practice, a natural support to Buddhist environmentalism, is being taught in a range of contexts. The basic teachings of the Satipatthana Sutta or the mindfulness text, cultivate awareness of breath, body, feelings, and mind. Walking and sitting meditation are used to generate a sense of centered presence and alertness. Such mindfulness generates appreciation and respect toward the natural world, with practices related to food and eating, time and place, and personal wellbeing. Those practicing mindfulness are encouraged to slow down, consider their actions carefully, and make every effort not to cause suffering to others, including plants and animals.

Most political battles play out as confrontations between apparent enemies: loggers verses spotted owl defenders, housewives verses toxic polluters, bird lovers verses pesticide producers. From a Buddhist perspective, this kind of dualistic hatred destroys spiritual equanimity. Thus it is much better to work from an inclusive perspective, offering kindness to all parties involved, even while setting firm moral boundaries against harmful actions. A Buddhist orientation to non-dualism can help to stabilize a volatile situation and establish new grounds for negotiation. Buddhist texts emphasize a strong relationship between intention, action, and karmic (actions in a previous existence) effects of an action. If an environmental campaign is undertaken out of spite, revenge, or rage, that emotional tone will carry forth into all the ripening of the fruits of that action (and likely cause a similar reaction in response). However, if an action is based in understanding that the other party is also part of Indra's Jewel Net, then things unfold with less antagonism.

Perhaps the most significant teaching of the Dharma relevant to Buddhist activism is the practice of *detachment from the ego-generating self*. Thus, a Buddhist approach to environmental activism would be non-heroic, i.e., not motivated primarily by the need for ego identity or satisfaction. Strong intention with less orientation to the self relieves the activist from focusing so strongly on results. One does what is necessary in the situation, not bound by the need to reinforce one's ideas or to have it turn out a certain way. Small b' Buddhists have been able to act as bridge builders in hostile or reactive situations by toning down the need for personal recognition. Cautioning against the self-serving ego, Buddhist teachers emphasize the power of *kalyana mitta*, or spiritual friendship: acting together in mutual support to help others practice the Dharma and take care of this world.

The Buddhist path of liberation includes the practice of physical, emotional, and mental awareness. Such practice can increase appreciation for the natural world; it can also reveal cultural assumptions about privilege, comfort, consumption, and the abuse of nature. Scholar Alan Sponberg suggests that a Buddhist environmental ethic is a *virtue* ethic, based fundamentally on development of consciousness and a sense of responsibility to act compassionately for the benefit of all forms of life. Through the practice of Green virtue ethics, modern teachers encourage students to be environmentally accountable for their actions, from eating food, to using a car, to buying new clothes. Through following the fundamental precepts, environmentally oriented Buddhists can practice moderation and restraint, simplifying needs and desires in order to reduce suffering of others.

RECENT HISTORY OF BUDDHISM AND ECOLOGY

In the last few decades, Buddhists around the world have responded creatively to environmental problems, drawing on principles of Buddhist philosophy and practice. Forest monks in Thailand lead meditation walks around polluted areas; Tibetans collaborate with western nongovernmental organizations (NGOs) to expose recent environmental destruction in Tibet. American Buddhists have worked on issues of consumerism, wilderness protection, and animal rights. One of the earliest voices for Buddhist

environmentalism was Gary Snyder, North American Zen student and poet, who illuminated connections between Buddhist training and ecological activism. In the 1950s and 1960s, members of the Beat generation and the 1960s counterculture explored these links further, saying that spiritual leadership was necessary to halt planet-wide ecological destruction.

In the 1970s the environmental movement swelled, and Buddhist centers became well established in the West. Some retreat centers confronted ecological issues head on. The Zen Mountain Monastery in New York faced off with the Department of Environmental Conservation over a beaver dam and forestry issues. The Green Gulch Zen Center in Northern California worked out water use agreements with its farming neighbors and with the Golden Gate National Recreation Area. At a time when vegetarianism was not a popular choice, most American Buddhist centers refrained from meat eating, often with awareness of the associated environmental problems. Several Buddhist centers made some effort to grow their own organic food.

By the 1980s Buddhist leaders were explicitly addressing the eco-crisis and incorporating ecological awareness in their teaching. In his 1989 Nobel Peace Prize acceptance speech, His Holiness the Dalai Lama proposed making Tibet an international ecological reserve. Vietnamese peace activist and Zen monk Thich Nhat Hanh spoke of *interbeing* using ecological examples. Zen teachers Robert Aitken in Hawaii and Daido Loori in New York examined the Buddhist precepts from an environmental perspective. The US-based Buddhist Peace Fellowship, founded in 1978, gave prominence to environmental concerns on its activist agenda.

In Thailand, village priests took the initiative to perform ritual ordination of significant trees as a symbolic gesture of solidarity with threatened forests. Other monks engaged in efforts to question economic development and its environmental impacts. Plastic bags, toxic lakes, and nuclear reactors were targeted by Buddhist leaders as detrimental influences on people's physical and spiritual health. Similarly, in Tibet and Burma, Buddhist environmentalists drew attention to oil pipelines, hunting of endangered species, and threats to unique habitats.

In the Western world, the topic of Buddhism and ecology was picked up by Buddhist publications, conferences, and retreat centers. The Buddhist Peace Fellowship produced a substantial packet and poster for Earth Day 1990. The first popular anthology of Buddhism and ecology writings, *Dharma Gaia*, was published by Parallax Press that same year, following the more scholarly collection, *Nature in Asian Traditions of Thought*. World Wide Fund for Nature brought out a series of books on five world religions, including *Buddhism and Ecology*. Buddhist magazines such as *Tricycle*, *Shambhala Sun*, *Inquiring Mind*, *Turning Wheel*, and *Mountain Record* devoted whole issues to the question of environmental practice.

In 1990 Middlebury College in Vermont hosted a conference on spirit and nature where the Dalai Lama stressed his commitment to protection of the environment. At the 1993 Parliament of the World's Religions in Chicago, when Buddhists gathered with Hindus, Muslims, pagans, Jews, Jains, and Christians from all over the world, a top agenda item was the role of religion in responding to the environmental crisis. Parallel interest in the academic community culminated in ten major conferences at Harvard University, defining a new field of religion and ecology. The first of these conferences, convened by Mary Evelyn Tucker and John Grimm in 1996, focused on Buddhism and Ecology (Tucker and Williams, 1997).

The academic community, however, did not address the *practice* of Buddhist environmentalism. This was explored by socially engaged Buddhist teachers such as the Dalai Lama, Sulak Sivaraksa, John Daido Loori, Philip Kapleau, Bernie Glassman, Christopher Titmuss and Thich Nhat Hanh. Joanna Macy developed a transformative model of experiential teaching designed to cultivate motivation, presence, and authenticity. Her methods were strongly based in Buddhist meditation techniques and the Buddhist law of codependent arising. Working with John Seed, Buddhist Australian rainforest activist, she developed a ritual Council of All Beings to engage people's attention and imagination on behalf of all beings (Seed *et al.*, 1988). Thousands of councils have now taken place in Australia, New Zealand, the US, Germany, Russia, and other parts of the Western world.

BUDDHIST ENVIRONMENTAL ACTIVISM

Examples of Green Buddhism on the front lines are still relatively rare. They reflect three major types of activism, which characterize environmentalism today: (1) holding actions of resistance; (2) structural analysis and alternatives; and (3) cultural transformation. Holding actions aim to stop or reduce destructive activity, buying time for more effective long-term strategies. In Northern California, a small group named the Ecosattvas has been protesting the logging of old-growth redwood groves. For one demonstration, they created a large prayer flag covered with human handprints to serve as a testimony of solidarity for those participating in the resistance actions. Later, several Ecosattvas made a pilgrimage into the heart of the Headwaters Forest, carrying a Tibetan treasure vase with gifts and prayers on behalf of the redwoods.

Moved by the suffering of animals in research cages, factory farms, and export trade stores, two Zen students in the San Francisco area formed a Buddhist animal rights group. Drawing on principles of non-harming, they educated Buddhists about the plight of monkeys, beef cattle,

and endangered parrots. One of them has continued this work in Europe, focusing on the cruelty of large-scale pig farming. Addressing the dangers of nuclear waste, a Berkeley-based study group protested the storage of nuclear waste below ground. As an alternative they developed a vision of nuclear guardianship for storage containers above ground that was based in Buddhist spiritual practice. In a parallel action, Zen student and artist Mayumi Oda helped to organize Plutonium Free Future and the Rainbow Serpents to stop shipments of deadly plutonium to Japan.

The second type of activism, structural analysis and the creation of alternative visions, has also engaged modern Buddhists. In 1997 the Soka Gakkai affiliated group, the Boston Research Center for the 21st Century, held a series of workshops addressing the people's Earth Charter, an internationally negotiated set of ethical guidelines for human–Earth relations. The center published a booklet of Buddhist views on the charter's principles to stimulate discussion before adoption by the United Nations (Morgante, 1997) (*see* Earth Charter, Volume 5). Members of the International Network of Engaged Buddhists and Buddhist Peace Fellowship started a Think Sangha to undertake structural analysis of global consumerism. Collaborating between the US and Southeast Asia, they held conferences in Thailand on Alternatives to Consumerism, pressing for moderation and lifestyle simplification.

The third type of activism, transforming culture, is barely underway and is sometimes met with resistance. Buddhist centers in rural Northern California, the Green Gulch Zen Center and Spirit Rock, and the Zen Mountain Monastery in New York already demonstrate a serious commitment to the environment through vegetarian food practices, land and water stewardship efforts, and ceremonies which include the natural world. In the Sierra foothills of California, Gary Snyder has been a leader in establishing the Yuba River Institute, a bioregional watershed organization working in cooperation with the Bureau of Land Management. Members have undertaken survey work, controlled burns, and creek restoration projects with the local community. Planning ahead, Snyder estimates the level of commitment necessary to reinhabit a place and build a community that might eventually span generations. The Zen Mountain Center in Southern California is beginning similar work, carrying out resource management practices such as thinning for fire breaks, restoring degraded forest, and limiting human access to preserve areas. Applying Buddhist principles in an urban setting, Zen teacher Bernard Glassman has developed environmentally oriented small businesses which employ local street people, selling products to socially responsible companies such as Ben and Jerry's.

Several Buddhist centers have developed lecture series, classes, and retreats based on environmental themes. The Zen Mountain Monastery offers Mountains and Rivers retreats based on the center's commitment to environmental conservation. These feature backpacking, canoeing, nature photography, and *haiku* (poems), as gateways to Buddhist insight. The Ring of Bone Zendo offers backpacking *sesshins* in the Sierra Mountains. The Green Gulch Zen Center co-hosts the Voice of the Watershed, a series of talks and walks across the landscape of the *two* valleys. The Manzanita Village in Southern California includes deep ecology practices, gardening, and nature observation as part of their mindfulness retreats.

Most of these examples represent social change agents working within Buddhist or non-Buddhist institutions to promote environmental interests. In addition to these organizational initiatives, individual Buddhists are taking small steps to align their actions with their Buddhist practice. Many people, Buddhists included, are turning to vegetarianism and veganism (not eating animal products) as more compassionate eating choices for animals and ecosystems. Others are committed to eating only organically grown food, as a way to support pesticide-free soil and healthy farming. Sulak Sivaraksa in Thailand insists that the Western standard of consumption is untenable if extended throughout the world. Some Buddhists have joined support groups for reducing credit card debt, giving up car dependence, and creating work cooperatives. For many students, environmental awareness and personal change flow naturally from a Buddhist practice commitment.

CONCLUSION

How might Buddhism and ecology affect the larger environmental movement and how might it influence Western Buddhism in general? Will Buddhist environmentalism turn out to be more environmental than Buddhist? The answers to these questions must be largely speculative at this time, since Green Buddhism is just gaining a footing. It is possible that this fledgling voice will be drowned out in the brownlash' against environmentalists, or in Western resistance to engaged Buddhism. Environmental disasters of survival proportions may overwhelm anyone's capacity to act effectively. The synergistic combination of millennialism and economic collapse may flatten Green Buddhism as well as many other constructive initiatives.

But if one takes a more hopeful view, it seems possible to imagine that Green Buddhism will grow and take hold in the minds and hearts of young people who are creating the future. Perhaps some day there will be Ecosattva chapters across the world affiliated with various practice centers. Perhaps Buddhist eco-activists will be sought out for their spiritual stability and compassion in the face of extremely destructive forces. Buddhist centers might become models of ecological sustainability, showing other religious institutions ways to encourage ecological culture. More Buddhist teachers may become informed about environmental issues

and raise these concerns in their teachings, calling for moderation and restraint.

That being said, Buddhism is not the only or necessarily the best path for dealing with the environmental crisis. Moral leadership and community organizing from all religious traditions are needed to stop the downward spiral of planetary ecological devastation. Committed practitioners of non-harming can inspire others who are trying to resist destructive practices. Ecologically articulate Buddhists can advance inter-religious dialogue to meet the challenges of global warming, over-consumption, and other systemic ills. Drawing on a Buddhist perspective, academics, policy analysts, and poets can bring fresh insights to once intractable problems.

What happens next lies in the hands of those who are nurturing this wave of enthusiasm for Green Buddhism. Religious leaders, teachers, and scholars as well as younger generations, full of energy and passion for protecting the home they love, will determine the shape of Buddhism and ecology in the future. As the rate of environmental destruction continues to accelerate, many forms of dialogue and activism are sorely needed. Buddhism and its environmentally supportive teachings have much to offer. Like other world religions, this ancient tradition is being called once again to offer its wisdom and teachings in yet another context.

Business-as-usual Scenarios

A *business-as-usual scenario* is also called a *surprise-free scenario*. The expression was invented by Herman Kahn to describe a baseline scenario from which alternative scenarios can be created. It is based on current trend data assuming that no unusual events change the direction of the trends. Kahn also said that the biggest surprise would be if the surprise-free scenario actually occurred. Contrary to popular belief, the business-as-usual scenario does not imply that current conditions will remain unchanged; instead, these conditions change in the forseeable future based on current dynamics.

Carson, Rachel Louise

(1907- 1964)

Rachel Louise Carson, scientist, author, and heroine to millions, launched the modern day environmental movement with warnings that humanity was poisoning itself and the biosphere. Her best selling book *Silent Spring* is her lasting legacy.

Rachel Carson was born in 1907 in Pennsylvania, US. From her landlocked childhood, her affinity for the oceans began with graduate work in biology at Johns Hopkins University in Baltimore, MD. Financial constraints prevented Rachel Carson's pursuit of a doctorate, and she assumed a teaching position at the University of Maryland. She continued her marine field research, teaching in the summer sessions at Johns Hopkins for 7 years. Her postgraduate research included studying at Woods Hole, MA. She became a government marine biologist and in the 1930s began her popular writing career with a series of articles in the *Baltimore Sunday Sun*. One expanded article was published in *The Atlantic Monthly*. That article ultimately was expanded into her first book, *Under the Sea Wind* (Carson, 1941). The publication 10 years later of *The Sea Around Us* (Carson, 1951) gave Rachel Carson commercial success and fame. She resigned her job as a government marine biologist to more fully dedicate herself to writing about the growing threats to the natural world she loved. Carson next published in 1955, *The Edge of the Sea* (Carson, 1955), her third book described as a poetic biography of the ocean. It was quickly followed by *The Sense of Wonder* (Carson, 1956).

The next phase of her life's work was to collect and research the evidence of the damage caused by chemical pesticides, unleashed as a new arsenal of synthetic toxic substances at the end of the Second World War. Her work on the subject was originally published in *The New Yorker* magazine and then in book form as Silent Spring in 1962 (Carson, 1962).

Silent Spring caused a storm of controversy. It became a best-seller, catalyzing environmental groups calling for the banning of dichlorodiphenyltrichloroethane (DDT) and other chemicals linked in Carson's work with widespread damage to wildlife and to human health. The chemical industry lobby was well prepared for *Silent Spring* and launched a merciless attack on Carson. Although she had expected denials and debate over her claims, she was unprepared for the highly personal nature of the charges. As her obituary in *The Baltimore Sun* noted, industry spokesmen tried to depict her as a neurotic, frustrated, hysterical personality of no scientific standing, a mere popularizer and hobbyist. Unmarried and childless, the industry argued that such a woman could not legitimately claim concern for future generations. Rachel Carson defended her well researched work with appearances before Congressional committees. What the public did not know was that even as *Silent Spring* was published, Carson was already fighting breast cancer, the disease that would ultimately take her life just 18 months after publication of her most critical work. Before her death, she fulfilled a lifelong dream, to see the California Redwoods with Sierra Club executive director, David Brower (*see* Brower, David, Volume 5). David Brower attributed her success by telling her publisher, Paul Brooks, she did her homework, she minded her English and she cared. (Brooks, *The House of Life*.)

Silent Spring remains a vitally important book 40 years after its publication. Far from stale, the book accurately anticipated many of the more subtle health risks of chemical pesticides, including endocrine disruption and xenooestrogenic effects. In Rachel Carson's own words, As crude a weapon as the cave man's club, the chemical barrage has been hurled against the fabric of life, *Silent Spring* (Carson, 1962). Despite her efforts and the movement she sparked, pesticide sales continue to soar and are now valued at tens of billions of dollars annually around the world.

CBA (Cost Benefit Analysis)

CBA is a method for evaluating public sector investments. It ideally considers all benefits (gain in utility) and costs (loss in utility) due to a project regardless of to whom they might accrue. CBA is also ideally timeless, in that all costs or benefits are considered, irrespective of when they may occur. The method simply weighs, in monetary terms, benefits versus costs. If benefits are greater than costs, then the project is potentially acceptable. There are three main challenges associated with the approach: measurement, valuation, and discounting.

The measurement of intangible costs and benefits may be difficult or inappropriate in some contexts. Aesthetic, cultural, ecological, or social utility may not be easily amenable to quantification. Beyond the problem of measuring a utility, the assignment of a monetary valuation can also be difficult. The use of shadow prices (imputed value for an item that has no clear market value) or surrogate markets (where a shadow price can be developed from a marginal rate of substitution or transformation) are sometimes used to address valuation problems. An important problem in valuation is the accuracy or representativeness of the value assigned to a benefit or cost, especially those that are inherently intrinsic.

Discounting (*see* Discounting, Volume 5) is the process of finding the value today of future benefits and costs. A rate of interest is applied to a sum (discounting is the reverse of compounding) to calculate present or future value. Future benefits and costs are discounted because of the belief in time preference (people prefer benefits today rather than in the future, thus a dollar today is worth more to an individual than a dollar receivable in one year), and because of the existence of a positive interest rate in the market. Discounting has the effect of reducing the scale of benefits and costs that accrue far into the future. A social discount rate is often used. It does not reflect a market rate, but is instead based on a social time preference rate or the social opportunity cost of capital. Discounting is criticized on the basis that it treats future generations unfairly. Depending on the choice of a discount rate, CBA may favor immediate consumption or diminish the value of environmental costs incurred far into the future.

Changing Human–Nature Relationships (HNR) in the Context of Global Environmental Change

see The Changing Human–Nature Relationships (HNR) in the Context of Global Environmental Change (*Opening essay*, **Volume 5**)

Chipko Movement

The Chipko Movement is celebrated globally by the environmental movement, heralded as a glorious example of eco-feminism, forest preservation, and local control over natural resources. The movement began spontaneously from a single incident in the Himalayan region of Uttar Pradesh, India in April 1973. Forested slopes around a village had been sold to logging concessions. Village women, fearing a loss of fresh water and destabilized slopes once the forests were gone, literally hugged the trees to prevent contractors from felling them. The word *chipko* means to embrace. Village women, Dhoom Singh Negi and Bachni Devi, among many others, spread the word with the Chipko slogan What do the forests bear? soil, water and pure air.

The movement has its roots in Gandhian theory and many prominent writers and philosophers became its leaders. The movement was embraced as a spiritual one, fitting the context of ancient Sanskrit scriptures, as well as other religions' invocation of the unity and oneness of life, by prominent philosopher and Chipko adherent, Dr Indu

Tikekar. The movement spread through many parts of the Himalayan region of Uttar Pradesh. In 1980, India's Prime Minister, the late Indira Gandhi, responded to public appeals with a 15-year moratorium on logging in the Himalayan forests of Uttar Pradesh.

The movement also included prominent men as leaders. Sunderlal Bahuguna, a Gandhian activist, whose appeal to Mrs Gandhi had proved successful, subsequently embarked on a two year, 5000 km trek by foot thorough the Himalayan regions, spreading the Chipko message beyond Uttar Pradesh. Bahuguna expressed his message as Ecology is permanent economy .

The expanded movement succeeded in stopping clear-cut logging in the Western Ghats and the Vindhyas. The Chipko movement continues to lobby for a new natural resources policy, more sensitive to local people's needs and ecosystem sustainability.

ELIZABETH MAY *Canada*

Christianity and the Environment

David G Hallman
World Council of Churches, Toronto, Canada

Western Christianity is a relative latecomer in recognizing and expressing concern about contemporary human assaults on ecosystems. The path of awakening for Christians has included not only growing awareness of the seriousness of the ecological crises but also the role that their own tradition has played in the relationship between human societies and their environments.

Some of the major tenets of western Christian thought and practice contributed to a perception of an exalted place of the human within the broader natural world which provided some of the legitimacy for scienti c, economic and technological exploitation of nature. But throughout the history of Christianity, there are also inspiring examples of individuals and schools of thought which championed a concern for the well-being of all creatures.

In recent times, Christians have become conscious of that checkered history and have become convinced that caring for creation needs to be a fundamental part of how they live out their faith in the world. In addition to the work of theologians reconceptualizing Christianity to respond to the ecological challenge, individual Christians, community parishes, and national and international ecumenical institutions have become active in addressing many of the threats to creation. However, the degree of Christian engagement in environmental concerns should not be exaggerated. It still represents a minority concern within the broader framework of theological, spiritual and social justice preoccupations.

Several communities of experience, often from the margins of the Christian mainstream, have had a particularly important impact on theological understandings of the relationship of humans to the broader natural world. In particular, eco-feminist theologians, indigenous peoples, and activists and ethicists from developing nations of the Economic South *have challenged the dominant approaches and have contributed insights that have deepened and, in some cases, redirected the focus of Christian involvement in environmental issues (see Note on Terminology, at the end of this article).*

Out of the plethora of environmental challenges facing the world, a number have become priorities for the engagement of the wider Christian ecumenical community and will likely grow as major challenges for the future. These include climate change, the exploitation of both humans and non-humans by the forces of the global economy and trade, and the spiritual values that can underpin a more sustainable relationship between human societies and the rest of the natural world.

HISTORICAL BACKGROUND

Christianity played a role in the development of the western industrialized economic model that is at the root of many of our current ecological problems. Hallman (1992) gives an analysis of the interconnections among science, religion and economics in the genesis of today's ecological crises and an identification of new models from the disciplines for living more sustainably. Through various sources, Christianity provided support for the scientific and industrial revolutions. From early in the Middle Ages, monasteries preserved and encouraged scholarship in classical Greek and Roman culture. Without this data base, modern intellectual development and scientific progress would have been immeasurably slowed. When Protestantism emerged, it emphasized the distinction between the Creator and the creature. In effect, the reformers desacralized the natural world and focused attention on humanity's standing and condition before God. This contributed to the study and manipulation of nature by the budding sciences. Francis Bacon contended that all Creation had meaning only in relation to humanity.

> Man, if we look to final causes, may be regarded as the center of the world insomuch that if man were taken away from the world, the rest would seem to be all astray, without aim or purpose.
>
> (Thomas, 1983)

Ian Barbour notes that: The desacralization of nature encouraged scientific study, though it also (along with other

economic and cultural forces) contributed to subsequent environmental destruction and the exploitation of nature (Barbour, 1990).

The industrial revolutions that followed the scientific revolution also benefited from religious attitudes of the day. Early Protestants believed in industrious, disciplined work as they shifted the religious focus from otherworldly to innerworldly asceticism. The blessing of economic success could be seen as an outer sign of inner faith and assurance of salvation. The virtues of frugality and simplicity, coupled with hard work and saving, converged with the needs of early capitalism. People worked hard and saved, but didn't spend on material indulgence: that was just the ethic needed to establish a capital base.

There was a sense of religious fervor among those involved in the early scientific and economic pursuits: God was beckoning humanity to use all of its intelligence to usher in a new day of enlightenment and prosperity. The natural world was seen as yielding its long-held secrets to the rigor of scientific experimentation. Economic theories were formulated to describe the unseen laws that governed supply and demand. There was a genuine conviction among the theologians, scientists and economists that God's will was being realized in their efforts.

Theological attitudes which viewed the natural world primarily as a God-given resource whose utility related to exploitation for human purposes continued as a dominant perspective until relatively recently. A document from the 1961 Assembly of the World Council of Churches (WCC) states that the Christian should welcome scientific discoveries as new steps in man's domination of nature (Granberg-Michaelson, 1994).

The pastoral constitution *Gaudium et Spes* of the Second Vatican Council expressed a general expectation that:

> ••• (human beings), created in God's image, received a mandate to subject (to themselves) the earth and all that it contains ••• thus, by the subjugation of all things to (humanity), the name of God would be wonderful in all the earth.

Though these broad streams of religious intellectual thought have contributed over the past several hundred years to a perception of the natural world as exploitable without consequence, there have been Christian spiritual voices offering a different perspective. Mystics such as Hildegaard of Bingen and St. Francis of Assisi articulated a reverence and valuing of all life for its own sake that contrasts with the more utilitarian approach of later Christianity. There have also been communities of religiously motivated persons over the centuries such as monastic orders, which practiced a conservation ethic in relation to nature around them. These earlier religious voices and practices concerned about the wellbeing of all creation have found new relevance during the past several decades as Western Christians have come to see the seriousness of the ecological problems facing the Earth.

THEOLOGICAL CHALLENGES

An American historian, Lynn White Jr, was one voice that did much to stimulate public awareness of the critique of Christianity in relation to environmental problems. In a famous 1967 article in the journal *Science* entitled *The Historical Roots of our Ecological Crisis*, White maintained that Judeo-Christian scriptures, theology and traditions must accept some responsibility for societal attitudes that allowed for exploitation of the environment (White, 1967).

The environmental criticisms leveled at Christianity by White and others shook theologians and lay Christians. Fortunately the response was not in the main defensiveness but rather the launching of an extended period of reflection, reanalysis of scripture and theology, and reconceptualization of models for the interrelationship of God as creator, the human species, and the rest of creation.

There are three main areas that have been identified in Christian theology and scripture as being particularly problematic. The most frequently cited is the concept of God giving humans authority over all creation:

> Let us make the human in our image, after our likeness; and let them have dominion over the fish of the seas, and over the birds of the air, and over the cattle, and over all the earth, and over every creeping thing that creeps upon the earth.
>
> (Genesis 1:26)

Theologians and biblical scholars have helped to place this seeming blanket mandate for domination into a context which highlights a range of conditionalities tied to this authority. In *Genesis*, the story of creation precedes the arrival of evil or the fall. Thus, the giving by God of this authority over other creatures occurred at a point where humans were without sin and hence would be expected to exercise that dominion in ways pleasing to God who created and loves the world. Secondly, there is another creation story in *Genesis* 2, which uses very different imagery for the human relationship to the rest of nature. The human is to till and keep the garden. This *dominion theology* perspective challenges an unrestricted exploitive authority that could be read into the first creation story.

Canadian theologian, Douglas John Hall, was an early exponent of *stewardship theology*, which sought to transform Christian approaches away from the unfettered dominion model toward one of responsible caring for the Earth. Hall (1982) argues that stewardship means that humans are given responsibility to care for the world as God's stewards. That is, humans do not own the Earth but are God's surrogate caretakers: The Earth is the Lord's and the fulness therof; the world and all that dwell therein (*Psalm* 21:1). To care for the Earth as God would care for it points to a much more responsible attitude since we believe that God loves the Earth. Further, as stewards, humans will be held responsible by the Master, for the care which they have exercised, or failed to exercise, on that which belongs to the Master.

A second theme in Christian theology which has been seen as posing problems for our relationship to the environment is the dichotomy which is identi ed between the spiritual and the physical. In the New Testament Epistles, we hear a number of references that would seem to counsel rejection of this physical world including the following:

> Do not love the world or the things of this world. If anyone loves the world, love for the Father is not in him.
>
> (*I John* 2:15)

> Do you not know that friendship with this world is enmity with God? Therefore, whoever wished to be a friend of the world, makes himself an enemy of God.
>
> (*James* 4:4)

However, biblical scholarship that gained added relevance as environmental awareness grew, has helped to place these letters to communities of early Christians into historical context. At a time when the general expectation was that the end of the world was at hand and that Christ would be returning soon, the writers were encouraging their readers not to place their faith in material wealth. While there has been a persistent thread over the centuries stressing the religious af rmation of creation s goodness, there have also been interpretations of these passages strongly emphasizing otherworldliness and rejection of this world. Environmentalists have worried that such theology could undermine a social attitude of concern for the wellbeing of the Earth.

A third concept that has been identi ed in the critique of Christian theology is the emphasis on personal moral will as the ultimate de ning characteristic of the human. While there are philosophical traditions that have also focused on moral agency, Christian theology has given it a particular priority. Though an emphasis on moral will does not of necessity lead to a negation of the value of the natural world, some of its implications seem to point in that direction. Since only humans exercise moral choice and judgement via rational processes, it was believed that higher value was attributed to the human than to the creatures lacking these capacities. The elevation of the rational capacities also implied the denigration of other attributes such as emotions, intuition, and sense perception itself.

NEW THEOLOGICAL DIRECTIONS

The critiques of Christianity by Lynn White Jr and others helped to unleash a robust period of theological reconceptualization regarding the relationship of humans to the rest of creation. In addition to these challenges from outside the religious community, there were also those within the faith who were shaking traditional approaches. The creation-centered work of Thomas Berry and Matthew Fox from within the Roman Catholic tradition provided a radical reorientation to understandings of the interrelationship of God, humanity and the rest of creation. Their writings would prove quite unsettling to the church hierarchy. *Stewardship theology* referred to above was another of the initial responses and did much to af rm that biblically sound and intellectually rigorous alternate understandings to *dominion theology* were possible.

Process theology has been a further approach that has widely in uenced the evolving Christian thinking about the ecological crisis. Based on the work of philosopher Alfred North Whitehead, process theologians such as Cobb and Grif n (1977) developed a systematic application of Whitehead s ideas with the emphasis on God s loving interrelatedness with creation. Cobb in particular has played a signi cant role through his writings in articulating the ecological implications of process theology (Cobb, 1972; Cobb and Birch, 1981; Cobb and Daly, 1989). One of his principal arguments has been the inherent interconnection between God, humanity and the natural world. ••• for process theology, as an ecological theology, human beings are part of nature ••• Humanity is seen within an interconnected nature (Cobb, 1972) .

German theologian Jurgen Moltmann comes to similar conclusions within the framework of his own theological analysis. In a book based on his Gifford Lecture series, Moltmann emphasizes the relationship of God to all creation as the starting point.

> An ecological doctrine of creation implies a new kind of thinking about God. The center of this thinking is no longer the distinction between God and the world. The center is the recognition of the presence of God in the world and the presence of the world in God.
>
> (Moltmann, 1985)

Through biblical analysis and systematic theological argumentation, Moltmann describes various manifestations and implications of the presence of the Spirit of God within creation. A consistent theme is the centrality of relationship as the most fundamental de ning characteristic of existence. Theological understandings such as Moltmann s and those of process theology echo and in some ways enhance scienti c discoveries and reconceptualizations of the 20th century which have also moved in the direction of an emphasis on the primacy of relationships within matter and the natural world.

Eco-feminist theologians have articulated perceptive analytic critiques of traditional Christian theology in terms of its destructive contribution to the ecological crisis and have posited new models for understanding the relationship between humanity and the rest of creation. While recognizing and recovering much rich insight in the Biblical scriptures that can help ground a new environmental ethic, eco-feminist theologians are nonetheless more prepared than some other theologians to acknowledge the ambiguity of the Bible. This stems in part from the broader feminist analysis that recognizes the cultural conditioning

of many of the scriptural writers working as they were in very patriarchal societies.

Eco-feminist approaches to reflection on ecological theology and ethics draw on a broad range of human capacities. Their methodology and the content of their analysis are interconnected in the recognition that our ecological problems are due in part to a hierarchical valuing of creatures and the attributes associated with them. Men have been seen as the most valued and the traditional male-oriented emphasis on rationality, control and exploitation has dominated both in human relationships and in terms of the Earth. Eco-feminists insist that intuition and emotion are indispensable as elements in the repertoire of human response if we are to make significant progress in solving our environmental problems. They argue that a reorientation toward the Earth will require a foundation of love and caring for life in its fullness not just rationalistic analyses and technological fixes (*see* **Ecofeminism**, Volume 5).

There are creative options proposed by eco-feminist theologians for new theological approaches to our relationship with creation. The *web of life* is one image that eco-feminists use to emphasize the interrelatedness and interdependence of the various elements of creation.

Sallie McFague has suggested reimaging God not only as father but also as mother (the nurturer of all life), as lover (the most intimate of relationships), and as friend (a constant and supportive presence) (McFague, 1993). Such models of God provide a deeper appreciation of the role of God as creator and sustainer of life and can contribute to values that would be more environmentally sensitive: e.g., as protection of life, joy and love in our relating to the Earth, and solidarity with the oppressed members of creation.

Chung Hyun Kyung (1994) has done much to popularize eastern religious and cultural appreciations for the unity of all life and the sacredness of creation. Bringing such insights into dialogue with more traditional Christian approaches has provoked considerable controversy. It is nonetheless an essential contribution if Western Christianity is to honestly acknowledge its cultural role in the economic development model which has come to dominate the global economy and to seek partnership with other faith traditions in building a value base for an Earth ethic.

Equally threatening to some Christians have been the insights being offered by indigenous peoples around the world. Struggling back after several centuries of cultural oppression by colonizing powers, many indigenous peoples are recapturing their traditions that include important understandings of ways in which to relate sustainably to the natural world around them. Western societies seeking to reconceptualise their relationship to the Earth could benefit from the rich contributions of indigenous creation stories, the understanding of nature as being members of one's family, rituals used to relate to the various seasons and creatures in the natural world, and concepts of community organization for long-term sustainability (Rajotte, 1998). Particularly helpful have been the writings of people of indigenous heritage who have connected native spirituality and Christian theology such as the American Indian George Tinker, Stan MacKay (a Canadian of Cree origin) and Rob Cooper (a Maori from Aotearoa, New Zealand) (Tinker *et al.*, 1994).

There has been a risk in the rejuvenation of native spiritual ecological insights that Christians and others might appropriate those concepts and rituals into their own practices in a romanticized manner without recognizing the historical context out of which those indigenous understandings emerged. In part to respond to this risk, indigenous peoples have raised tough political and economic issues related to the ongoing oppression of their cultures and societies in addition to sharing elements of their native spirituality. Christian communities have been challenged to acknowledge and repent of their role over the past centuries as agents of cultural genocide. Some churches and ecumenical organizations have acted in solidarity with indigenous peoples in their struggles in local, national and international forums.

Theologians, ethicists and activists involved in environment and development issues in countries of the economic South have been another source of critical social, economic and political critique of the western development model and its links to Christian traditional understandings of the relationship of humans to the rest of creation.

Theological contributions from the economic south on issues of ecotheology have been relatively recent. Theologians and ethicists from these countries have understandably been more preoccupied with the economic struggles of their countries which have suffered 500 years of exploitation by imperialistic nations, colonializing powers and now global financial institutions. Countries in Latin America produced a vibrant movement of liberation theology that played a pivotal role in articulating the ethical basis for a systemic social, economic and political critique of the western economic model and its historical exploitation of the south. However, many of the liberation theologians were as anthropocentric and utilitarian in their orientation toward the non-human elements of the natural world as were the tradition Christian theologians of the North.

However, as the depth of the ecological crises became more apparent as well as their interlinkages with the western economic development model, theologians and ethicists from countries of the *Economic South* began to make important connections between the historical struggles of their countries and environmental problems. Moreover, justice for the poor had always been the primary focus of liberation theologians and it was becoming clear that the poor were also the most vulnerable to the health and social effects of environmental problems.

Leonardo Boff from Brazil is among the more prolific and insightful theologians who has sought to develop an integrated approach to socio-economic issues and environmental concerns. While recognizing the contributions of various critical responses to the prevalent social model such as liberation movements, pacifist and non-violence groups, and ecological movements, Boff argues for the need for a more integrated approach.

> It is important today to articulate these different critiques of the dominant system. However, we must urgently seek to develop a new paradigm for society that does not repeat the mistakes of the old but integrates all human beings in a more humane way and establishes more benevolent relationships with the environment.
>
> (Boff, 1994, 1997)

The insights and analyses of theologians, ethicists and activists from countries of the *Economic South* have had a significant impact on the work on environment and development issues by churches and ecumenical organizations such as the WCC (*see* WCC (World Council of Churches), Volume 5). Theologian Jesse Mugambi from Kenya has enriched ecumenical understandings of the social, economic and environmental impacts of colonialization in Africa and has articulated nuanced analyses of so called globalization and the homogenization processes where a few power centers dictate the rules for the rest of the world. Aruna Gnanadason from India who is working currently as a staff member of the WCC has provided leadership in the integration of gender justice with ecology and economic development.

It is impossible to note all of the influential theologians and ethicists who are contributing today to deepening Christian reflection on the implications of the ecological crisis and what the faith has to offer as constructive responses. Mary Evelyn Tucker, John Grim, Dieter Hessel and Rosemary Ruether, all of whom have done writing in their own right, have made a very important contribution through the organizing of the April 1998 Conference on Christianity and Ecology on behalf of the Harvard University Center for the Study of World Religions. The resulting book includes contemporary reflections by many of the most important theologians and ethicists concerned today about the ecological crisis.

Larry Rasmussen and Dieter Hessel have produced a book that looks at implications for the church of engagement in ecological issues after bringing together a wide range of theologians, ethicists, and practitioners for a 1998 Conference on Ecumenical Earth, at Union Seminary in New York. Rasmussen (1996) has also written an ambitious integrative book *Earth Community, Earth Ethics* which combines analyses of the interrelated crises of environmental degradation and global economic injustice with the articulation of new visions that integrate biblical reflection, theological rigor, and inspiring spirituality.

I would also add some of my own writing to this list of attempts to take the richness of the theological and ethical debates and make it more popularly available to a wider Christian audience, for instance, *A Place in Creation - Ecological Visions in Science, Religion and Economics* (Hallman, 1992) and *Ecotheology - Voices from South and North* (Hallman, 1994).

CHURCH ENVIRONMENTAL RESPONSES AT LOCAL, NATIONAL AND INTERNATIONAL LEVELS

To write about Christianity and the environment is not just to discuss the theological and ethical reflections that have propelled the faith into serious confrontation with the ecological crisis. That rejuvenated faith, having had its eyes opened to the seriousness of the problems, its own historical complicity, and most importantly, new models of engaging theology and spirituality in relevant responses, is being expressed in action.

Church denominations in many parts of the world have prepared educational and action resources to assist their members learn more about environmental problems within an ethical and spiritual context and to offer opportunities for activities to make a constructive difference:

- US churches circulated information packets and lobbying suggestions to congregations at Earth Day to encourage them to press for effective endangered species legislation.
- German churches did a study of energy use in churches as a prelude to a campaign to become more energy efficient.
- Philippine churches ran educational programs on forestry and collaborated with other social groups in a campaign for a moratorium on wide scale logging.
- Tanzanian environmental workshops were held for church and community leaders and included work on specific projects such as dam building to preserve badly needed water for irrigation.
- Dutch churches encouraged members to reduce their carbon dioxide emissions from transportation 3% per year.
- Zimbabwean churches have integrated tree planting into their liturgies.
- Japanese Christians collaborated with Buddhists, Shintos and members of New Religions to host an interfaith gathering and march during the 1997 session of the UN negotiations on climate change in Kyoto.
- Argentinean Catholic, Orthodox, Protestant, and Episcopal churches worked together to host an ecumenical service during the 1998 session of the UN negotiations on climate change in Buenos Aires.
- Swedish churches bought parcels of forestland to ensure that they are harvested in a sustainable manner.

- Canadian churches advocated against plans for the premature and potentially dangerous disposal of high level nuclear wastes.
- The Ecumenical Patriarch of Constantinople has sponsored environmental education programs for youth and a special seminar focused on environmental problems around the Black Sea.

The list could include many more examples of efforts by churches at national and local levels to translate their faith into practice in caring for the well being of creation. Persons involved in organizing such efforts will be the first to acknowledge that, though progress is being made, it remains an ongoing struggle to convince the churches as institutions and the individual members of the importance of engagement in environmental issues.

At the international level, several ecumenical organizations, especially the WCC, have played a role in both fostering theological and ethical reflection on ecological concerns as well as facilitating the active engagement of their member churches in specific issues. An important consultation was organized by the WCC in 1974 in Bucharest and brought together scientists, economists and theologians to discuss implications of the recently published study of the Club of Rome *Limits to Growth*. One of the important contributions of this event was the articulation of the concept of sustainability, the idea that the world's future requires a vision of development that can be sustained for the long-term, both economically and environmentally. During the 1970s, the WCC had a program on the just, participatory and sustainable society (JPSS), which included the Energy for My Neighbor project which was intended to sensitize churches about energy problems faced by developing countries and to activate practical steps to ameliorate the energy situation of those in need, and the Massachusetts Institute of Technology (MIT) Conference in 1979 on Faith, Science and Technology, which became known primarily for its controversial position on nuclear power.

In 1983, the WCC Assembly in Vancouver adopted a process-focused action plan on justice, peace and integrity of creation (JPIC) through which churches were encouraged to work together on these interrelated themes. Many churches became increasingly attentive to environmental concerns during this period, adopting policy statements and initiating education and advocacy activities on specific issues. The JPIC process culminated in a World Convocation on Justice, Peace and Integrity of Creation in Seoul, Korea in 1990, at which a series of ten theological affirmations and specific covenants for action were approved. They provide a description of the interrelatedness of economic inequity, militarism, ecological destruction, and racial injustice and the theological, ethical and spiritual basis for affirming and sustaining life in its fullness.

There have also been a number of occasions of interaction between Christian theologians and leaders of other living faiths, focused on rediscovering the important contributions from within the traditions and sacred writings of each of the faith systems, which could help move human societies toward greater respect for the natural world. One of these events was an interfaith consultation hosted by the WCC in August 1991 to develop proposals for inclusion in an Earth Charter.

The 1992 United Nations Conference on Environment and Development in Rio de Janeiro provided an opportunity for witnessing to the spiritual dimensions of the ecological crisis. Many faiths were represented at the Rio Earth Summit and held joint vigils, ceremonies and workshops. The WCC sponsored a major ecumenical gathering bringing to Rio 150 representatives of churches from over 100 countries for two weeks of prayer, worship, study and involvement in the Earth Summit. Particularly important were the connections made with many other non-governmental organizations representing environmental groups, development bodies, and women's networks.

During the 1990s, the WCC work on environment-related issues focused primarily on global climate change, monitoring the work of the UN Commission on Sustainable Development, and beginning a more significant engagement in ethical issues raised by the growth in the biotechnology industry.

CHALLENGES FOR THE FUTURE

Climate change has become one of the major foci for international ecumenical activity on ecological issues and is likely to continue to be so as the threat increases. Not only does climate change represent a threat to the well-being of God's Earth but it is also a profoundly ethical issue since it is being precipitated largely by the rich industrialized countries while the consequences will be suffered disproportionately by the poorer developing countries and by future generations.

The ecumenical community through the WCC has participated in the UN negotiations on climate change treaties since 1989. In 1996–1997, the WCC sponsored an international petition campaign to build greater public pressure on the governments of industrialized countries to take action to reduce their emissions as a lead up to the Kyoto Summit in December 1997. The WCC made a major statement on climate change as an issue of justice at the Kyoto Summit (World Council of Churches, 1997). Churches in many countries have organized educational and advocacy activities and have sponsored ethical reflections on climate change within the context of models for sustainable societies. These programs have been accompanied with resources to assist individual members take practical steps in their own homes, lives and communities to reduce energy use and contribute to limiting the emission greenhouse gases.

A second major challenge which will likely increase in importance for the Christian community in the future is the interconnection of the environment and the global economic system. These are well illustrated in the climate change issue but they also go beyond and encompass global trade, the role of multinational corporations and international financial institutions, and the scandalous economic inequities between peoples of the world. The ecumenical community has a long history in advocacy and action for economic justice and a more recent history with environmental issues. These two become interconnected when dealing with the implications of increasing economic globalization. Addressing globalization will pose a challenge to the churches in terms of their capacity for analysis of complex systems, resources to be engaged from local to global levels and the strength to persevere despite intense pressure that can be mounted by the vested power structures being critiqued.

A third challenge for the future is the reconceptualizing of the churches' important environmental activity in a spirituality that can both inspire the work and sustain those involved. Throughout western culture generally, there is a widely perceived thirst for spiritual nourishment to counter the bareness of contemporary consumerism and materialism. Institutional religion is aware that many people find its forms of worship and engagement do not adequately satisfy their spiritual needs. Thus, both Christians active in social and environmental issues within churches and non-Christians outside the church, feel the need for greater spiritual nourishment. Concern for the well being of the Earth is one area where a nurturing of spiritual values can be linked intrinsically with a justice agenda.

NOTE ON TERMINOLOGY

Terminology is very complex when trying to describe different regions of the world today. In United Nations (UN) parlance, reference is made to developed and developing countries to distinguish between the richer primarily northern and western industrialized nations and the poorer primarily southern nations. However, many people object to that vocabulary because it implies a higher level of technological and social sophistication for the developed countries. Third World was another term that was current for some time but that has also fallen out of favor because again it suggests an ordering of value or worth in comparison with the First World. A distinction between the North and the South has become more utilized because most of the poorer nations are south of the equator and south does not carry any particular value connotation. Not all of the poorer countries are in the geographic south and there are some industrialized nations in that region. Hence, for my purposes in this paper and in my other recent writings, I have come to use the phrase countries of the *Economic South* to denote the poorer nations. While I recognize the clumsiness of the phrase and the increasing difficulties in making generalizations between the North and the South in our increasingly complex world, this is the designation that I find most satisfactory to date.

Circulating Freshwater: Crucial Link between Climate, Land, Ecosystems, and Humanity

Malin Falkenmark
Natural Science Research Council and Stockholm International Water Institute (SIWI), Stockholm, Sweden

A simplified holistic view is presented of humanity s present environmental predicament as seen from a freshwater perspective. Like the doctor who bases much of his diagnosis of a patient on his blood system, its circulation and quality characteristics, the author bases her diagnosis of the world ecosystem of which Man is a part on the bloodstream of the biosphere, i.e., the water cycle. The aim is to identify the most crucial actions in future-oriented decision-making. In contrast to a widespread but false belief that water is very simple and can be handled within the water sector, many parallel functions and manifold appearances have to be taken into account when addressing the interaction between human society and the physical landscape hosting its life-support system. Fundamental regional differences in terms of both vapor ow of green water involved in biomass production, and liquid ow of blue water available for societal use in aquifers and rivers are highlighted. It is shown that the developing world at present experiences a threefold escalation: of water stress, of water dispute proneness, and of water pollution load. Analysis suggests that water accessibility constraints will increasingly disturb global food security. Escalating food needs make it particularly important to find ways of reconciling upstream/downstream con icts of interest especially as intensified upstream biomass production (agriculture, forestry) easily leads to downstream river depletion. Such depletion will generate increasingly severe problems for water-dependent societal activities and aquatic ecological services downstream.

TIME TO LOOK AT THE BLOOD SYSTEM OF THE BIOSPHERE

One thing characterizing our time is the predicament in which environmental decision makers nd themselves: squeezed between two shields. On the one hand, the public expects them to repair the environmental damage that has already materialized; on the other, the public expects them to be forward-looking and ensure that growing demands on socio-economic development will not make the problems even worse.

A necessary basis for future-oriented decision-making is a minimum of basic understanding of fundamental relationships between humans and the natural landscape hosting their life-support system (freshwater, biomass production, presence of minerals and energy sources, etc.). Past studies on environmental effects of human activities have not produced such an understanding but often got caught up in the considerable complexity of ecosystem behavior. Moreover, one fundamental component the water cycle acting as the bloodstream of the biosphere tends to be absent in many such studies (Falkenmark, 1997). Equally remarkable is the lasting land/water dichotomy and the considerable conceptual barriers to realizing the water dependence of land use and biomass production. In the water community, the alertness to water scarcity problems (CFWA, 1997) tends to be concentrated to allocation problems within the so-called water sector (water supply for household, industry, and irrigation). This attention is, however, quite recent. Most countries have probably not started to deal with it but pursue supply strategies, as in the past. Not much attention is being paid to upstream/downstream con icts of interest.

It is getting increasingly clear that humanity s genuinely water-dependent future cannot be discussed without attention to water s deep involvement in many different functions in both nature and society. For example, potential water-related constraints to global food production are starting to send serious concerns through the scienti c community (Falkenmark, 1997b; Falkenmark *et al.*, 1998 and references therein). The nite character of the freshwater circulating on the planet has made it essential that the water requirements for food production be properly entered into global water resources assessments.

This situation has made it necessary to expand our attention from the conventional water sector focused on societal use of the liquid ow of blue water in aquifers and rivers to include also the vapor ow of green water involved in rainfed biomass production in agriculture, forestry and natural vegetation systems (Figure 1) (Falkenmark and Rockstrom, 1993).

Evidently the plants do not mind if the water available to the roots is naturally in ltrated rainwater or external irrigation water that has been added from groundwater or surface water. Since the land cover is instrumental in the rainwater partitioning process at the ground surface, land

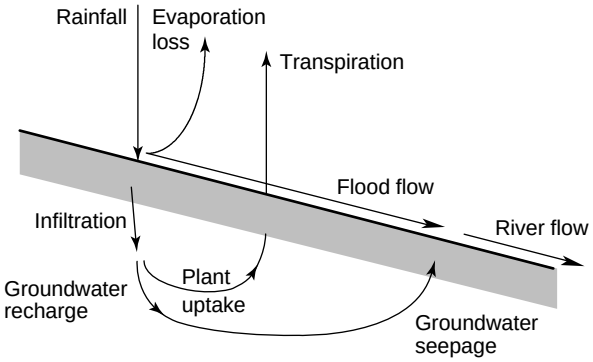

Figure 1 The rainfall partitioning into the vertical green water branch, encompassing productive and non-productive components, and the semi-horizontal blue water branch, encompassing the water in groundwater aquifers and rivers

use changes tend to alter the partitioning of the incoming rainfall between these two water flows, and therefore influence the blue water that is available for allocation within the water sector.

The water cycle sets a large-scale exterior constraint to both human and natural life. The aim of this article is to tie together a whole set of water-related phenomena within a joint conceptual framework. This framework starts from the basic interactions between human society and the life-supporting landscape in which we live. It demonstrates the enormous management problems that population growth generates due to water's deep involvement in these interactions, and identifies a set of urgent actions.

TECHNOSPHERE AND BIOSPHERE SHARE THE SAME BLOOD SYSTEM

It is probably not much of an exaggeration to state that water is the most misunderstood component of life. It is mistakenly taken as quite simple, since it is part of everybody's daily life. In reality it is extremely complex with many parallel functions in both nature and society: health function, habitat function, psychological and religious functions, carrier functions (solutes, silt), and production functions (green-water dependent biomass production, blue-water dependent socio-economic production). Successful environmental management therefore critically depends on our ability to address such complexity.

Water fills all living beings, it has vital functions on all scales – from the planetary scale down to the cell scale. It is a universal solvent, carrying nutrients to the cells and waste products away from the cells. In the life-support system, it acts as a carrier of dissolved matter, as a key food substance for both humans and fauna, as a key raw material in plant production, and as a habitat for aquatic flora and fauna. In society it functions almost as a lubricant of industrial development through all its key functions in industrial production (carrier, solvent, washer, cooler). At the same time, water is a key operator in different collapse-driving processes: as carrier of microbiological disease agents to humans, in its tendency to form floods and inundations, as eroding agent, and as contaminant carrier in general.

Since all ecosystems are water-dependent, water is fundamental as a silent messenger in generating ecosystem degradation and biodiversity disturbances from human manipulations of the landscape.

To facilitate communication on these complex issues, the following simple metaphor may be helpful (Falkenmark, 1997a). Human activities in the landscape can be illustrated as involving interaction between a social sphere and a landscape sphere. The imperative in the social sphere is to satisfy the basic needs of the population of water, food, energy, etc. and meet their aspirations in terms of goods and services. Performing this involves manipulations of land and water in the landscape for harvesting the natural resources there (water, biomass, energy, minerals). These manipulations are physical (clearing, tilling, drainage, well drilling, pipes and canals) and chemical (agricultural chemicals, waste produced in the social sphere and disposed of in the landscape: to the air, to the land, or directly to the water bodies). Since the natural laws operate in the landscape, side effects are produced, building up into air pollution, land degradation, water degradation and as higher order effects, i.e., ecological degradation. If the needs and aspirations of the inhabitants are not satisfied or as a response to frustration raised by the exacerbating environmental side effects, reactive responses occur in the social sphere: passive ones like famine, poverty, diseases, disputes, suffering, or active ones like riots, environmental migration, policy changes, etc.

Water's multifunctional involvement in the interaction between human society and the physical landscape is reflected in its manifold appearances in terms of:

- the provision of water supply for various societal activities;
- water as a resource manifested as availability in rivers and aquifers, water involved in the production of plant substance from carbon dioxide from the air and water from the soil; streaming water as a source of energy; and water bodies as habitats for aquatic biota;
- side effects of human landscape manipulations manifested as water quality degradation; altered seasonality in the rivers; escalating floods, river depletion; and aquatic ecosystem degradation;
- water-related diseases, societal damage by inundations, etc.

The sectorial organization of society implies that also the political driving forces on demands on the water that

flows through the landscape are sectored and unconnected although they are all dealing with the same water (Falkenmark, 1997a):

- the health authorities are interested in water supply and sanitation to protect against water-related diseases, high morbidity and mortality;
- the agricultural authorities are responsible for crop production to keep famines away, generating raised water requirements, often also land degradation;
- the environmental authority is responsible for habitat protection to avoid ecosystem degradation and problems with protein nutrition;
- the economic development authority is responsible for industrial production, thereby generating increasing water requirements, often also pollution loads.

The tunnel view tendency in each of these sectorial bodies introduces an incoherence in decision-making that explains much of the past difficulties in coping with emerging environmental problems.

A CLOSER LOOK INTO THE UNDERLYING WATER PROCESSES

Landscape manipulations, that are necessary to harvest the natural resources, generate side effects through:

1. the water partitioning of incoming precipitation in its interaction with soil and vegetation;
2. water's function as a universal solvent continually moving down the landscape in the river basin;
3. the integrity of the water cycle circulation, transferring impacts of human manipulations along the chain from atmosphere to land and terrestrial ecosystems to groundwater and rivers to water bodies/lakes and aquatic ecosystems to coastal waters and marine ecosystems (Figure 2).

The first of these links can be further clarified by referring to the distinction earlier indicated between two complementary types of water flows (cf. Figure 1):

- the invisible vapor flow back to the atmosphere – referred to as green water flow which is part of the plant production process;
- the liquid flow passing above and below the land surface – referred to as blue water flow – and consisting of the surplus or non-evaporated precipitation.

Food, fodder, fiber, fuelwood and timber are all produced by green water, and thereby involve a consumptive use (Lvovich and White, 1990) which is of the order of $600-6000\,m^3$ of water per ton biomass produced, depending on the hydroclimate. Human societies (municipalities, industries, irrigation schemes, etc.) are run by blue water withdrawn from rivers and groundwater. Such uses tend to add a pollutant load to the water when returned to the river.

In its contact with the land surface, incoming precipitation passes two partitioning points (Falkenmark, 1986):

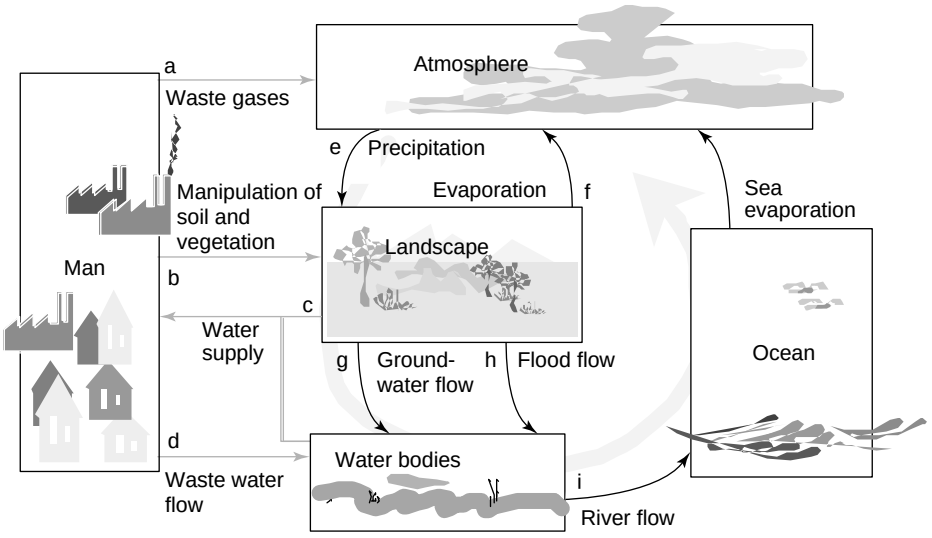

Figure 2 Mental continuity-based image of the water cycle, linking the net sea evaporation, the wetting of continental landscapes, the recharge of aquifers, the flood flows in rivers, and the river discharge back to the sea. Man's interactions are indicated by the four horizontal arrows to the left: (1) waste gas output to the atmosphere; (2) manipulation of soil/vegetation – physically and chemically; (3) water withdrawals from aquifers and rivers; (4) wastewater output to water bodies. When the population grows, these arrows will grow in size, whereas the water-flow arrows in the system will change only when climate changes

- at the soil surface, dividing the precipitation between flood flow and infiltration;
- in the root zone, dividing the infiltrated water between plant uptake and groundwater recharge.

Since land use activities modify soil and vegetation, they also influence this partitioning and therefore both the amount of river flow and its seasonality (fluctuations between low flow and high flow). Land conversions that involve major vegetation changes tend to impact this water partitioning, and result in green/blue water redirections, traditionally spoken of as water balance changes.

Deforestation typically reduces the green water return flow to the atmosphere and therefore increases the flow in the blue water branch (a typical result is water logging (*see* **Waterlogging**, Volume 3), as happened on the Hungarian Plain, increased river ow, or ood ows). In South Africa, a major campaign is now employing over 42 000 people to eradicate invasive alien plants, that are more water consumptive than the natural vegetation. The campaign has double objectives: on the one hand to increase the blue water ow that is available to support society s water needs, on the other to restore degraded biodiversity.

Reforestation works the opposite way, easily producing river depletion. In South Africa afforestation and reforestation after more than 5 years is allowed only with issued permits (van der Sel, 1997). Due to the importance of this land/water linkage, in the South African government water issues are handled by a joint Ministry of Water Affairs and Forestry. The frequent recommendation of forest plantations to protect vulnerable soils from crusting and erosion easily neglects the lower partitioning point in Figure 1 while concentrating all its interest on the upper one. This neglect may lead to surprising river depletions developing as unexpected side effects of the plantations.

The second link is related to the combined effect of water both as a solvent and as a substance involved in key chemical interactions between the in ltrating water and the geological surroundings taking place in the root zone (Falkenmark and Allard, 1991). It is widely known that the water-divides formed by the hilltops in the landscape de ne the water ow modules, i.e., the drainage basins, each enclosed by its own water divide. Therefore, the precipitation that does not return to the atmosphere as green water, forms blue water and either feeds the river with rapid ood ow or passes underground as groundwater ow, seeping back to the surface in springs, local hollows and valley bottoms.

A slope in the landscape is typically divided into uphill recharge areas where the rainwater moves downwards through the root zone, recharging the groundwater and downhill discharge areas where groundwater returns back to the land surface. In the recharge areas, bogs may develop, fed by precipitation. In the local hollows, groundwater-dependent wetlands develop; and in the valley bottoms the groundwater seeps back to the surface and either evaporates, feeds riparian forests or recharges the water courses with a time-stable ow. In the riparian zone, groundwater and ood dependent riparian wetlands may develop.

The chemical composition of the natural water develops as the in ltrating water passes from recharge to discharge areas (Falkenmark and Allard, 1991). It rst interacts with two systems: the organic root zone system which adds carbon dioxide and humates, making the water aggressive, and the soil system from where available minerals are picked up. As the water arrives down into the groundwater zone it has acquired two cardinal characteristics: alkalinity/acidity and redox potential (*see* **Redox Potential**, Volume 2). These two in combination determine what the water picks up along its continued underground pathways through deep soil and bedrock. The resulting chemical composition in the seepage zone, where the rising water meets oxygen again, characterizes the biodiversity there.

The third link relates to the continental part of the water cycle as such. The global water cycle links the ocean, the atmosphere, the land and its terrestrial ecosystems, the water bodies and their aquatic ecosystems, and the marine water and coastal and marine ecosystems. The water cycle is the mega-desalinization plant of the planet on which life here depends. It is energized by the energy from the sun. On the continents water is moving above and below the ground surface under the law of gravitation.

The third link is illustrated in Figure 2 where man s interventions with the cycling water has been distributed among the different compartments as indicated by the four arrows to the left:

- waste gas output to the atmosphere;
- manipulation of the soil/vegetation physically and chemically;
- water withdrawals from aquifers and water bodies;
- waste water output to water bodies.

When population grows these arrows grow in size, whereas the circulating water ow will change only when climate changes.

FUNDAMENTAL REGIONAL DIFFERENCES IN CHALLENGES

Now that this basic mental image of the interaction between society and the physical landscape hosting the life-support system has been explained and discussed, the next step is to explore fundamental regional differences in the principal system: on the one hand those related to the hydroclimate in uencing the green water ow, on the other the differences in the blue water ows.

It is thought-provoking to note that most industrialized countries are located in the temperate zone. There, water blindness is widespread and people tend to take water for

granted. Unfortunately, it seems that water blindness is widespread also, however, in the South. The poorest countries are in the dry climate tropics and subtropics where the everyday question number one is where to find the water and food needed to survive. The fact that many colonial powers in the tropical and subtropical countries based their understanding on natural conditions in temperate climates invites the question whether their decisions were environmentally deleterious and introduced rather than eliminated environmental problems.

Turning next to fundamental blue water differences (renewable water only), Figure 3 gives a global level overview of the water resources situation in the world today. The present level of water withdrawal (use to availability ratio or technical scarcity) is shown against the population pressure on water (number of individuals sharing each flow unit of water or demographic water scarcity) (Falkenmark and Lundqvist, 1998). In this diagram, different levels of *per capita* water use (in cubic meters per person and year) show up as a diagonal line.

Moving up the vertical scale is costly and means more reservoirs, canals and pipelines but also more administration. Experience suggests that when withdrawals exceed 20% of the availability, investments for reservoirs, transfers, irrigation schemes, etc. start to be costly as seen in the national economy. Moreover, in dry climates it is difficult to mobilize more than 50% due to evaporation losses from reservoirs. One hundred percent is only possible to reach by large scale waste water reuse, by underground storage, or where a large river passes right through a country so that the water is easy to access. Moving along the horizontal scale, on the other hand, means more water competition and disputes, and increased pollution load since there are more people polluting each flow unit of water.

In this diagram, the world regions form five rather distinct clusters with radically different water resources predicaments:

- truly water-scarce regions with high population pressures on water resources, technically close to the hydrological ceiling – altogether 1.6 billion inhabitants in 1995 and rapid population expansion;
- the water spenders, i.e., regions with a moderate to high water mobilization level, moderate population pressure, and very high *per capita* water use due to large scale, low-efficiency irrigation – altogether a rather stable population of 0.3 billion;
- an average-level set of regions, moderate in all three senses – mobilization levels, population pressure and *per capita* use – altogether 2.5 billion and some of them with ongoing population expansion;
- a group of water rich regions with low mobilization level, low population pressure, and moderate *per capita* use – altogether a rather stable population of 0.8 billion;
- an outlier group with low mobilization level and *per capita* use – a rapidly growing population – currently 0.4 billion people.

The diagram suggests that population growth is pushing large parts of the world towards the right, i.e., a situation

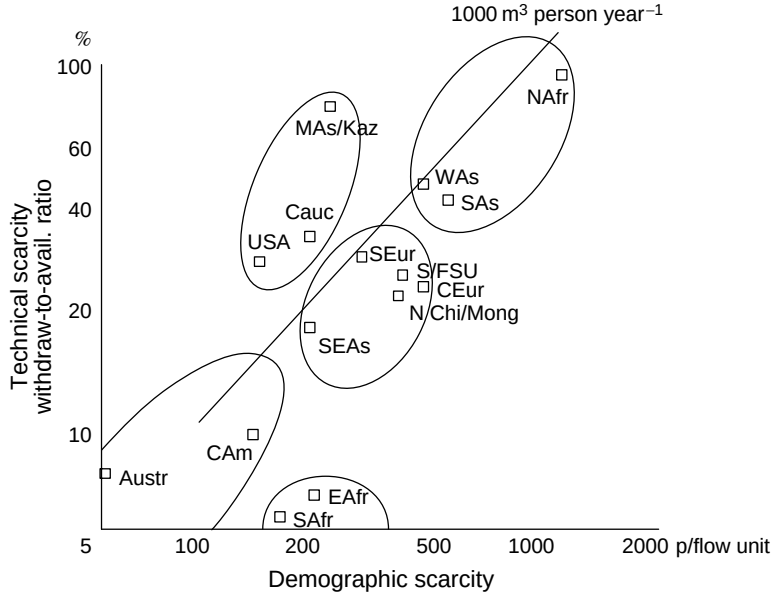

Figure 3 Fundamental regional differences in the water scarcity predicament. The figure shows characteristics in terms of demographic and technical water scarcity, respectively, for Shiklomanov's 26 global regions. The diagonal line shows *per capita* water withdrawal of 1000 m^3 person^{-1} year^{-1}, needed for food self-sufficiency in semiarid tropics and subtropics. (Data from Shiklomanov, 1996)

of growing dispute proneness and pollution loading. Ultimately, a growing proportion of available water will no longer be usable due to too much pollution (Lundqvist, 1998). This is evidently a real danger to socio-economic development in the developing world since it may lead to societal stagnation wherever industries employing large groups of the population are closed down by court orders, due to excessive water pollution, or where pollution-driven frustration generates riots and social unrest. There are several cases, for example in India where this process is starting to develop.

Figure 3 can also be used to see the implications of population growth for food production (Falkenmark, 1997b). Most critical is the extra blue water needed to secure food supply in dry climate regions, where yields are low due to water shortages and plant damage from dry spells. The situation was recently explained in a Round Table on water scarcity and global food insecurity in *Ambio* (Falkenmark *et al.*, 1998). It was assumed that, in semi-arid climates (where most of the rapidly growing populations are), maybe 50% of crop water requirements may be provided from infiltrated precipitation, while irrigation has to contribute the remaining 50%. This adds up to a blue water need of $800\,m^3\,year^{-1}$. Adding another $200\,m^3\,year^{-1}$ for households and industry leaves us with a water need of $1000\,m^3\,year^{-1}$ altogether. Many regions are moving to under the food self-sufficiency line, and will increasingly become dependent on food imports.

This analysis suggests that water will increasingly limit food self-sufficiency possibilities in dry climate regions with rapid population growth. Countries that will not be able to stay self-sufficient, due to lack of accessible water, should study their comparative advantages in order to find out what to export in exchange for food imports.

FROM HYDROEGOISM TO HYDROSOLIDARITY

What are then the key challenges of the near future when it comes to finding out what some of the crucial actions would be? The overriding task is to successfully cope with environmental preconditions while satisfying societal needs. Evidently, water's flow through the river basin links human activities upstream with opportunities and problems downstream. Therefore, downstream societies are in a sense the prisoners of the upstreamers (Figure 4).

Human interactions with the water can be divided in two categories: water-dependent activities and water-impacting ones. Man's water-impacting activities are basically of three kinds: land use conversions (influencing blue/green water partitioning, as already indicated in the above discussion of deforestation and reforestation); water withdrawals/flow management (influencing river flow and low/high flow seasonality); and the addition of pollution loads.

It has in particular to be realized that water use may involve consumptive water use (Lvovich & White, 1990); most of the water withdrawn for irrigation is evaporated into the atmosphere. The result is downstream river depletion (e.g., Aral Sea basin, Yellow River in China). After non-consumptive use, on the other hand, where water is used in a through-flow based manner, the water used goes as a return flow either to groundwater or to the river, generally carrying a pollution load of agricultural chemicals, industrial and/or municipal pollutants.

Downstream water users and ecosystems will suffer from these changes in water quantity and quality. Protection of downstream water interests for wetland protection and conservation of biodiversity will demand conservation of a certain minimum flow. Some experts say that at least 25 percent of the river flow has to remain for downstream ecosystems, others that 75 percent has to remain. Such criteria are evidently equivalent to posing constraints on acceptable upstream consumptive use and pollution load respectively, i.e., upstream food production. The conflicts of interest here, in other words, involve existentional issues for humanity that will now have to be honestly faced.

It is extremely important that these upstream/downstream conflicts of interest be adequately realized. True negotiating

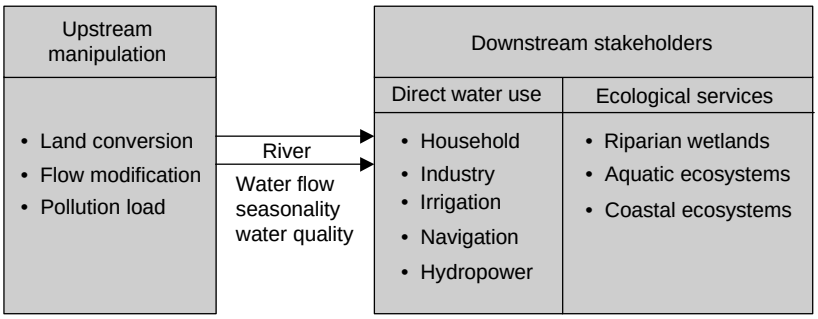

Figure 4 Conflicting stakeholder interests in terms of water-impacting activities and water-dependent activities, respectively, for which reconciliation methods will have to be developed

arenas will have to be developed so that the unavoidable side effects of manipulations, required for the satisfaction of societal needs, can be analyzed and discussed in an intentional way rather than arriving as unintentional surprises as has often been the case in the past (Rockstrom *et al.*, 1999).

THREE CRUCIAL TASKS FOR THE NEXT 30 YEARS

It is clear from the above that the present predicament, particularly of the developing world, includes three phenomena:

- escalating water competition;
- escalating dispute proneness;
- escalating pollution load.

On the regional scale, the upstream/downstream dependencies within river basins involve major challenges related to evident con icts of interest, whether the river basins are national or transnational, shared amongst several countries. Fortunately, there is probably also a proneness to create institutions that facilitate cooperation.

A set of fundamental regional differences have to be kept in mind (all regions suffer from recurrent oods):

- In western countries the key problem is water pollution (basically chemical) reducing water usability, threatening human health and aquatic ecosystems downstream.
- In newly industrialized countries (post-communist countries and monsoon-climate countries in the humid tropics) the key problem may be water shortage during the dry season (lack of dilution water) and/or a combination of microbiological and chemical pollution.
- In the lowest income countries the key problem is dif culties in making water accessible for use (small rivers go dry most of the year, large rivers are international), water competition is escalating, and dispute proneness and pollution loads are rapidly growing as water demands for socio-economic development increase.

This overview suggests that three key challenges have to be urgently addressed:

1. Supplying food in water-short countries, unable to feed their rapidly growing populations. This may be foreseen to involve expectations of a six-fold export from temperate zone countries (the breadbasket of the world) to help feed these water-short countries unless continued forest clearance for rainfed agriculture be accepted as a vital weapon in a global strategy to feed humanity.
2. Ensuring that water remains usable for all the societal sectors depending on it. This points to the critical need to go from today s willful neglect of water pollution to a situation where both industry and agriculture take water pollution seriously, and try to minimize their contributions (Lundqvist, 1998).
3. Developing mechanisms for con ict reconciliation between upstream land and water use, and downstream water use and ecosystem services (Falkenmark, 1998). This points to the crucial need to develop a water ethic, which has to be up to date and based on an understanding of how the life-support systems function.

If society has to manipulate land and water and those manipulations inevitably produce side effects, then the creation of a sustainable development policy which does not undermine its own resource base must be an issue of balancing the manipulations needed against the side effects produced (Falkenmark and Suprapto, 1993). Criteria are needed for this balancing: both human-ecological (groundwater must remain drinkable, land must remain productive, crops and sh must remain edible); ecological (biodiversity and crucial ecological services must be preserved) and socio-economic (poverty and hunger must be eradicated, and income generated).

HUMAN RIGHTS AND HUMAN OBLIGATIONS: BROADENING THE PERSPECTIVE

As already indicated the general belief that the water issue is very simple and can be handled within a water sector is altogether false. In reality it is as complex as the ow of blood in the human body. A doctor would never make his diagnosis of a sick patient without considerable attention to his blood system.

The past neglect in environmental sciences of water s many different roles in the interaction between development and environment has seriously delayed a proper understanding of so-called environmental problems and led to much lip service and redundancy in statements at international meetings. The price paid in terms of human suffering cannot be quanti ed but it can be noted that since the Stockholm Conference on the Human Environment, the world population has expanded by some 2500 million, mainly in the developing countries where the environmental problems have only gotten larger.

Much stress is presently being put on human rights to water; an example of our careless language. What is tacitly being referred to is not water as such but the provision of safe household water. The fundamental importance for humanity s future of nding ways for peaceful sharing of the precipitation falling over a joint river basin between

those living upstream and those living downstream, however, suggests that there is an even larger need for human water solidarity. In the future, human water obligations have to be given equal weight to the right to safe household water. Given a situation where upstream and downstream countries tend to have tremendous problems in agreeing on issues on the sharing of transboundary water systems, this indicates the need for seeking support from religious and philosophical circles in the search for a water ethics.

Commons, Tragedy of the

Tragedy of the commons is used to refer to a situation in which people who share in the use and benefits of a resource are inclined to damage or over-use it. Examples include

public lands, fisheries, waterways and public byways, the airwaves, and the atmosphere. Those who use this phrase typically assume that the word commons means that access is open to all; from that premise the argument is that the rational user of a common resource has no incentives for self-restraint (Hardin, 1968). There is no way to assure that other users will not take advantage and that the one who tries to conserve will be able to reap the benefits in the future. This idea is often used as an explanation for local, regional, and global environmental degradation and as a rationale for either government intervention in or privatization of resources used in common. However, it is important to recognize that in many cases access to resources held in common is not open access; and that they are managed through rules agreed upon by the users, as well as user-generated systems for monitoring and enforcement (McCay and Acheson, 1987; Ostrom, 1990). This is true for many local-level communities using forests, grasslands, fisheries, and other common resources, and it is also true for many international environmental regimes. Consequently, a second meaning of tragedy of the commons is the situation in which government intervention, privatization, and other factors diminish the effectiveness of local and user-based institutions for common resource management, creating environmental problems. Related are situations in which resettlement schemes, violence, or privatization programs result in the displacement of people dependent on commonly held access rights, intensifying their poverty and, in many cases, forcing them to intensify their use of marginal and vulnerable natural systems or to become part of urban-industrial systems.

Cousteau, Jacques

(1910- 1997)

Jacques-Yves Cousteau was a French oceanographic explorer and filmmaker who was best known for his prime time television series in the 1960s and 1970s, his role in the development of the first self-contained underwater breathing apparatus (SCUBA) equipment, and his advocacy for conservation of the marine environment.

Cousteau had no formal education in science or engineering. However, later in his career he was awarded honorary degrees (DSc) from California, Harvard, and Ghent. He entered the French Naval Academy in 1930, and eventually reached the rank of captain. His initial intention was to be a navy pilot but he seriously injured one of his arms in a car accident, ending his flying career. He started swimming to strengthen his arm and developed his love for swimming in the sea. Cousteau subsequently experimented with goggles, snorkels and other diving equipment. Cousteau and Emile Gagnan, an engineer from Paris, developed the Aqua-Lung (i.e., the first SCUBA gear) in 1943. This revolutionized diving since it freed divers from heavy diving suits requiring cumbersome air hoses and lifelines. The invention allowed free swimming and facilitated greater exploration of the ocean.

During World War II, Captain Cousteau conducted espionage for the French Resistance. He received decorations (e.g., Croix de Guerre) and was made Knight of the Legion of Honour for his efforts. After the war and with money from a British philanthropist (Thomas Loel Guinness), he acquired a decommissioned American-constructed minesweeper that had served in the British navy. He used this ship, the *Calypso*, for ocean exploration until it sank in Singapore Harbor in 1996. Cousteau and Jean Mollard, an engineer, developed a miniature submarine known as the Diving Saucer (1959) that allowed deep sea observation. He also developed other underwater equipment, conducted studies on underwater living and helium–oxygen diving techniques, and improved color photography by perfecting the underwater camera.

Cousteau greatly raised public awareness of ocean issues as a prodigious author and filmmaker. His book, *The Silent World*, published in 1953, was enormously

successful. It sold five million copies and was translated into 22 languages. His subsequent extensive number of highly successful books included *The Living Sea*, *The Whale - Mighty Monarch of the Sea*, and *Jacques Cousteau's Calypso*. His 1956 film, *The Silent World*, won the Academy Award for best documentary. He also won Academy Awards for *The Golden Fish* (1959) and *World Without Sun* (1964). Cousteau's series of television documentaries, *The Undersea World of Jacques Cousteau* (1968–1976), popularized marine issues and educated the public. By the end of his career he had written or contributed to more than 50 books and at least 150 films.

Jacques Cousteau earned numerous honors during his 70 year career. He was the director of the Musse Oceanographique of Monaco for 31 years (despite lacking a science degree), a member of the United States National Academy of Sciences and a member of the Academie Francais. Other honors include the Special Gold Medal of the National Geographic Society (1961), placement on the United Nations Environment Programme's Global 500 Roll of Honour for Environmental Achievement (1988), and the James Smithson Bicentennial Medal from the Smithsonian Institute (1996). Despite these honors, he has stated that he felt his success in increasing public awareness and concern for the ocean was his greatest achievement. The efforts of Jacques Cousteau for advocacy and promotion of ocean conservation are continued by the Cousteau Society Inc., which he founded in 1973.

Deep Ecology

Deep Ecology is the most fundamental form of ecocentrism. Its holistic view considers that humans are not separate from nature and that the earth, Gaia, is one organism, whose every (interdependent) part has intrinsic value. Current abuse of nature ultimately stems from inappropriate belief systems, most particularly Christianity, and the classical scientific worldview developed in the West during the Enlightenment. These are held to encourage anthropocentrism and attitudes of separation from and superiority to nature. Such attitudes are termed *shallow*, whereas Deep Ecology (the distinction was made in 1972 by the philosopher Arne Naess) is considered so because it fundamentally challenges such Enlightenment Project assumptions. *See* Enlightenment Project, Volume 5.

Deep Ecology celebrates richness, diversity and equality among all Earth's creatures, holding that humans have no right to reduce this richness and diversity except to satisfy vital needs. The lifestyles and practices stemming from such a principle emphasize simplicity, frugality, self-reliance, steady-state economics and limiting human population size. Invoking Aldo Leopold's land ethic, Deep Ecology regards human intervention in nature as inherently destructive. It seeks instead to preserve and expand wilderness areas.

Deep Ecology criticizes classical science's contemporary monopolization of respectable approaches to knowing the world and nature, seeing the predominance of rational thought as endemic to the anthropocentrism that has produced ecological crisis. By contrast, deep ecologists advance intuition as an equal or even superior form of cognition. Through intuition, they argue, the continuity between the human self and the rest of the cosmos may be properly apprehended and appreciated. Hence, drawing on diverse influences such as Heidegger, Buddhism, native American insights and Western romanticism, Deep Ecology calls upon people to develop a quasi-mystical ecological consciousness by which they will feel themselves part of the natural world, as a self-in-self.

Social Ecology and Eco-socialism roundly criticize Deep Ecology for displaying reactionary and anti-humanist tendencies.

Demographic transition

Wolfgang Lutz and Anne Goujon
International Institute for Applied Systems Analysis (IIASA), Laxenburg, Austria

The global demographic transition was the salient feature of world population changes throughout the 20th century. It is the reason underlying the population explosion that brought world population size from 2.5 billion in 1950 to six billion in 2000. But it is also the explanation why birth rates have been declining around the world and are expected to further decline where they are still high. As a consequence, population growth has already leveled off in many developed parts of the world and is expected to level off in all parts over the course of the 21st century. A decline in birth rates does not immediately result in the stabilization of population size, due to the fact that a very young population - a consequence of past high fertility - results in an increasing number of potential parents over several decades. This phenomenon is called the momentum of population growth.

In 1945, Frank Notestein developed the paradigm that all populations undergo a process of demographic transition at some point in their history. The *demographic transition theory* has evolved as a generalization of the sequence of events observed in what are now developed countries. The model distinguishes four phases in the evolution of populations. In the initial phase of the transition, the combination of high birth and death rates produces a slow or no growth equilibrium. That happened throughout most of human history: The world population grew slowly because birth and

death rates uctuations cancelled each other (see Figure 1). In the second phase, death rates begin to fall because of exogenous factors such as rise in living standards (better nutrition, hygiene) and improvements in health. This phase is a period of rapid population growth. The demographic transition theory asserts that in the third phase, and after some delay, the decreases in mortality will be followed by a decrease of fertility rates. During this phase, the population growth rate will decrease. The latter phase is when there is a quasi equilibrium between low birth and death rates.

Different societies have experienced transition in different ways, and today various regions of the world are following distinctive paths (Tabah, 1989). Many developed countries are in the last, fourth stage, or even beyond that, as many European countries have reached below replacement fertility levels and seem to stay at those levels. All world countries have gone through the second stage of the transition (mortality decline) and most are in the third stage of fertility decline or at a post-transition stage.

The demographic transition began in more developed countries (MDCs) in the 18th century and spread to less developed countries (LDCs) in the last half of the 20th century (Notestein, 1945; Davis, 1954, 1991; Coale, 1973). In MDCs, mortality rates declined comparatively gradually beginning in the late 1700s and then more rapidly in the late 1800s; fertility rates declined, as well, after a lag of 75 100 years. The demographic transition started much later in LDCs. The rst sign of a decline in mortality rates only appeared during the period between the two world wars. Average annual population growth rates doubled to reach 1% year^{-1}. Nevertheless, it was only in the 1950s and 1960s that the diffusion of medical techniques and progress in public health allowed the global population growth rate to increase dramatically. It reached 2.4% during the 1960 1970 period for the developing world.

The broad result has been a gradual transition from a small, slowly growing population with high mortality and high fertility, to a large, slowly growing population with low mortality and low fertility. On the theoretical level there are two different ways to explain demographic transition. In one view, the fertility decline is a direct response to the mortality decline. This so-called homeostasis argument claims that societies tend to nd an equilibrium between births and deaths. When death rates decline due to progress in medicine and better living conditions, the equilibrium is disturbed and the population grows unless birth rates decline in response to the new mortality conditions. The fact that fertility tends to decline many years after a decline in mortality may be explained by a perception lag. The equilibrium is supposed to be attained by a country when it reaches replacement-level fertility; that is an equilibrium in which each generation exactly replaces itself. The replacement fertility level depends on the sex ratio at birth, as well as on the mortality between birth and the end of reproductive life. In countries that are through the stage of mortality decline (all MDCs and some LDCs), the level of replacement fertility is about 2.1 children.

The alternative to the homeostasis argument assumes that modernization of society acts as a driving force of both declining mortality and declining fertility. Fertility decline lags behind mortality decline, according to this view, because fertility is embedded in the system of cultural norms more strongly than mortality, and therefore changes more slowly. The historical record of Europe where fertility sometimes declined simultaneously with mortality and population growth was generally much lower than in today s high fertility countries tends to support the second explanation. But the two arguments are not necessarily mutually exclusive.

Figure 2 illustrates the example of demographic transition in two countries: Austria, a developed country in

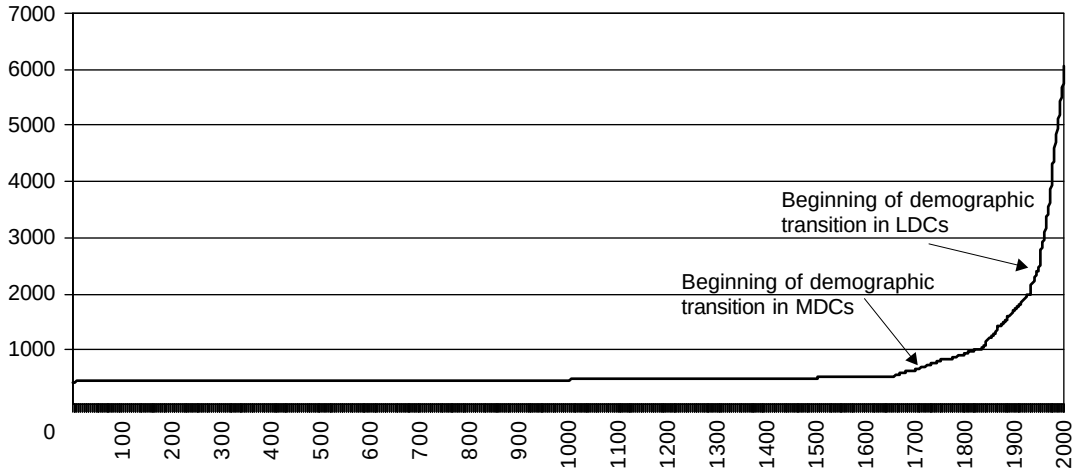

Figure 1 World population, 1 AD to 2000 AD

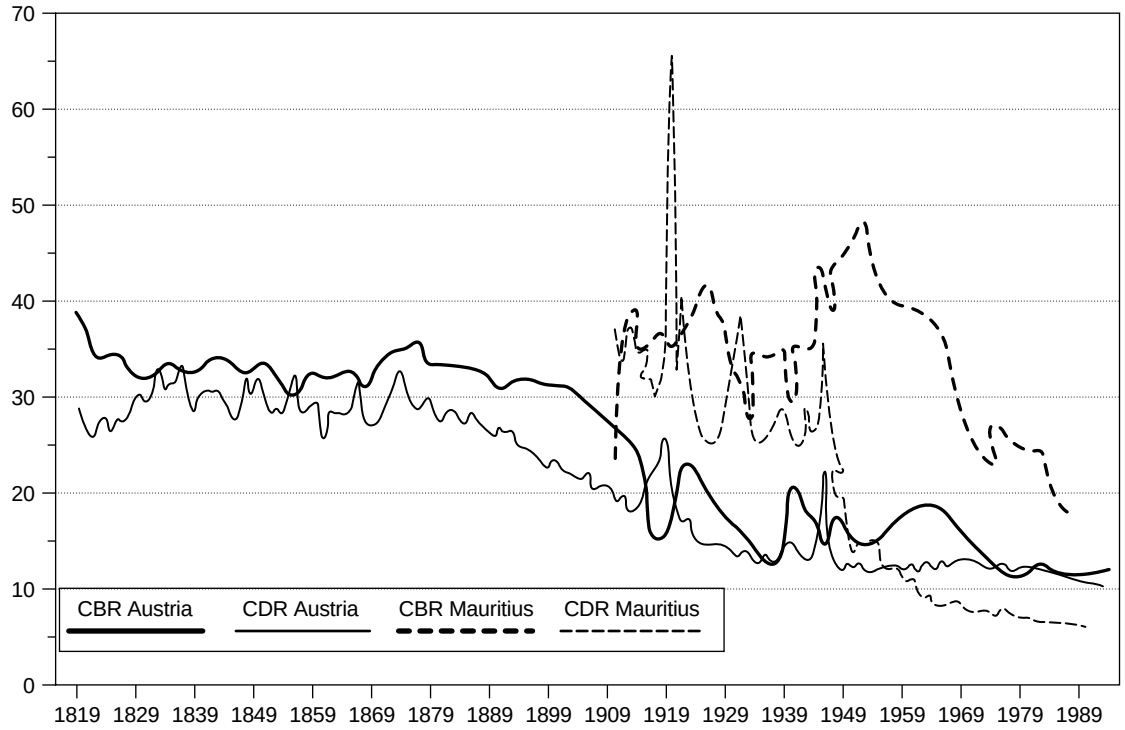

Figure 2 The demographic transition in Austria and Mauritius, crude birth (CBR) and death (CDR) rates

Central Europe and Mauritius, a developing country in the Indian Ocean. Both nations have good records for birth and death rates going back more than a century. Until about 1880 in Austria, annual birth and death rates fluctuated widely. These fluctuations can also be observed in Mauritius until 1945, due to epidemics, the changing severity of endemic diseases (notably malaria), and changing weather conditions (cyclones). Whenever birth rates are consistently above death rates, as was the case in Mauritius during the late 19th century, the population grows.

After 1880 in Austria, death rates started to decline until they had reached approximately their present level after World War II. The decrease in mortality rates started 70 years later in Mauritius but the decline was much more abrupt than in Austria. Death rates in Mauritius declined precipitously due to malaria eradication and the introduction of modern medical technology. Although the speed of the mortality decline and original levels of mortality were different in the two countries, the two developments were of the same nature. However, in the Austrian case, birth rates started a slow decline soon after the death rates, which is somehow typical of European countries, thus supporting the validity of the modernization argument mentioned above.

On the contrary, in Mauritius, birth rates remained high or even increased somewhat due to the better health status of women (a typical phenomenon in the early phase of demographic transition). By 1950 this had resulted in a population growth rate of more than 3% year^{-1}, one of the highest in the world at that time. Birth rates subsequently declined, with the bulk of the transition occurring during the late 1960s and early 1970s when the total fertility rate declined from more than six children per woman to less than three within only seven years, probably the world's most rapid national fertility decline. This decline occurred on a strictly voluntary basis and resulted from the combination of high female educational status and well-implemented family planning programs (Lutz, 1994). Because of the still very young age structure of the Mauritian population, current birth rates are still higher than death rates and the population is growing by about 1% year^{-1} despite fertility at around replacement level.

Empirically observed trends in all parts of the world have overwhelmingly confirmed the relevance of the concept of demographic transition to LDCs. With the exception of pockets where religious or cultural beliefs are strongly pronatalist, fertility decline is well advanced in all regions except sub-Saharan Africa, and even in that region many signs of a fertility transition can be perceived. In Southeast Asia and many countries in Latin America, fertility rates are on par with rates seen in MDCs only several decades ago, and in several countries, such as China, Taiwan, and Korea, fertility is at sub-replacement levels. In Southern Asia and North Africa, the demographic transition has not followed the pattern of a clear lag between the

decrease in death rates preceding a decrease in birth rates. The two rates declined almost simultaneously, somehow resembling the historical European pattern over the last 40 years.

The biggest difference between the demographic transition processes in what are now the MDCs and LDCs has been the speed of mortality decline. Mortality decline in Europe, North America, and Japan came about over the course of two centuries as a result of reduced variability in the food supply, better housing, improved sanitation, and, finally, progress in preventive and curative medicine. Mortality decline in LDCs, in contrast, occurred very quickly after World War II as a result of the application of Western medical and public health technology to infectious, parasitic, and diarrheal diseases. Life expectancy in Europe rose gradually from about 35 years in 1800 to about 50 in 1900, 66.5 at the end of World War II, and 74.4 in 1995. In LDCs, it shot up from 40.9 at the end of World War II to 62.1 in 1995. The increase was particularly impressive in Eastern Asia, where life expectancy at birth increased from around 40 to more than 70 years over that period. In Africa it only increased to slightly above 50 years, with life expectancy now falling in several countries due to AIDS. The increase that took MDCs about one and a half centuries to achieve came to pass in LDCs in less than half a century. As a result of the speed of the mortality decline, populations in LDCs are growing three times faster today than did the populations of present-day MDCs at the comparable stage of their own demographic transition.

Major social and economic changes, often summarized by the notion of modernization, are at the heart of the demographic transition theory. The changes in fertility trends are only one aspect of the radical social changes that many developing societies are experiencing. Cultural change, urbanization, and mass education have spread the image of the smaller nuclear family. It is to be expected that within the first decades of the 21st century, the final stages of demographic transition will be reached in all parts of the world.

Development

see Development and Global Environmental Change (*Opening essay*, **Volume 5**)

Discounting

Discounting is a method of weighing monetary values that occur in different time periods (Portney and Weyant, 1999). The construction of a dam, for example, entails large expenditures on labor and materials while the dam is being constructed; revenues from hydropower accrue over the next 100 years, say, with relatively minor operating costs. Will the value of electricity over the next 100 years pay for the construction costs and provide investors a market return? Investors convert values at different time periods to a present value equivalent by discounting to the present. One dollar put in the bank at 10% interest is worth \$1.10 in a year, thus \$1.10 (a year from now) has a present value of \$1. If the \$1 were left in the bank for two years, it would be worth \$1.21 (1•1 × 1•1), or \$1 (two years from now) has a present value of 1•1•21 = 0•826. More generally, investors are interested in the net present value (NPV), i.e., whether the present value of the benefits is greater than the present value of the costs.

$$\mathrm{NPV} = \sum_{t_0}^{n} \frac{B_t - C_t}{\bullet 1 + r \bullet^n} \qquad \bullet 1 \bullet$$

where B_t is the benefit or revenue in year t, C_t is the costs in year t, and r is the rate of interest.

Economists justify discounting future benefits and costs in public decisions because both investors and consumers appear to discount future returns and costs. Furthermore, future harms can be offset by investing pennies today.

For example, suppose one tonne of carbon dioxide (CO_2) emissions in the year 2000 imposes $1000 of costs on individuals living in the year 2100. With investments earning 8%, those generating the emissions could offset the $1000 loss by investing a mere $0.45 today.

A very important caveat is in order. Discounting is inappropriate when society determines on ethical grounds that future generations should have the right to particular environmental or other conditions. Howarth and Norgaard (1995) have shown that when rights are assigned to future generations, the economy can still operate efficiently. For example, people may determine today that it is unethical to subject future generations to the unknown risks of global warming. Climate change would be averted on ethical grounds. The economy can still function efficiently given the new understanding of the rights of future generations, but those in the present generation who benefit from the prior distribution of rights would be worse off.

Earth Charter

The success of such global efforts as the International Declaration on Human Rights led planners of the UNCED to initiate negotiations for an Earth Charter. Beginning in August 1990, the Road to Rio process of preparatory meetings aspired to draft an inspiring, meaningful and relevant call to a new relationship between humanity and the biosphere. The effort engaged many non-governmental organizations (NGOs), particularly those within the faith community. Various drafts were circulated by the Society of Friends, the Buddhists and the Franciscan Institute (devoted to the life of Saint Francis of Assisi).

But negotiations fell apart before the 1992 Earth Summit. In an exchange that captured the differing visions of delegations, north and south, Canadian Ambassador Arthur Campeau urged that the statement be free of United Nations (UN) bureaucrat language; that it be simple, clear and inspiring, the sort of document you could hang on a child's bedroom wall. To which a delegate from a developing country responded, Our children don't have bedrooms.

The failure to achieve an Earth Charter saddened a number of its promoters, notably secretary general of UNCED, Maurice Strong. It was Strong who subsequently ensured that the fifth anniversary of Rio (Rio Plus 5, March 1997) launched a renewed effort to draft an Earth Charter. Strong co-chaired an Earth Charter Commission, with former President of the USSR, Mikhail Gorbechev, and included an impressive roster of past and current heads of government, celebrities, indigenous people, parliamentarians, religious leaders, youth and activists. The Commission released a benchmark draft in March 1997 and held a three year process of public outreach and debate. The chief drafter, Steven Rockefeller of Middlebury College, Vermont, traveled the world collecting thousands of interventions. Difficult balancing and negotiation took place to develop a document that could be acceptable across various and very diverse cultures, religions and social norms. In March 2000, the group met to finalize and approve the document. It will be presented to the UN at the special session marking 10 years since the Earth Summit in 2002.

The Earth Charter attempts to set out a framework of ethics and values to re-define the way humanity interacts with the natural world. Unlike previous environmental statements, such as the Stockholm and Rio Declarations, the Earth Charter has a profoundly spiritual basis. It acknowledges the concern for individuals within a species to be protected from cruelty. It enunciates the need for the practice of non-violence and not merely the absence of conflict.

The Earth Charter's fundamental commitments are to:

> respect the Earth in all its diversity; care for the community of life with love, understanding and compassion; build democratic societies that are just, sustainable and peaceful; secure Earth's bounty and beauty for future generations.

The intent is to secure a place for the Earth Charter as soft law through seeking widespread public support from around the world.

ELIZABETH MAY *Canada*

Earth Day

The first *Earth Day*, April 22nd, 1970, was nearly exclusively an event observed only within the US, but by its 13th anniversary, April 22nd, 2000, the event was global and involved half a billion people in over 100 countries.

Earth Day's humble beginnings grew out of the anti-Vietnam War movement's effective use of teach-ins on college campuses in the 1960s. US Senator Gaylord Nelson and Denis Hayes organized the first Earth Day as a consciousness-raising and educational event. The US

was reeling from news that Lake Erie was dead due to eutrophication, as proclaimed on the cover of *Life* magazine, and the chilling warnings of Rachel Carson's *Silent Spring*, less than a decade before. Earth Day gained rapid acceptance and was marked by a Presidential Proclamation signed by the then US President Richard Nixon. Large US corporations, such as General Motors and Coca Cola, joined in declarations of corporate environmentalism.

The success of the 1970 event can be tied to the passage of key environmental protection legislation in the US, such as the Clean Air Act, as well as the creation of governmental environment departments, a trend that was solidified by the first United Nations Conference on the Human Environment in Stockholm in 1972.

Earth Day's founders had initially not intended the day to be celebrated annually. Subsequent Earth Days have reflected the ebb and flow of public environmental support. Earth Day 1971 was a much smaller affair than that in 1970; while Earth Day 1990 was huge, Earth Day 1991 was nearly invisible. Denis Hayes was once again the chief organizer of Earth Day 2000, which focused on climate change. As a millennial bash it succeeded in gaining media attention, with a full special edition of *Time* magazine devoted to it. April 22nd has emerged after three decades as having a firm hold on the name *Earth Day*.

ELIZABETH MAY *Canada*

Earth First!

Earth First! (EF!) is the brainchild of an angry environmentalist and self described redneck, Vietnam veteran Dave Foreman. Al Gore, in *Earth in the Balance* (published in 1991), quotes Foreman as saying, It's time for a warrior society to rise up out of the earth and throw itself in front of the juggernaut of destruction, to be antibodies against the human pox that's ravaging this precious beautiful planet.

Seeing so much destruction of vanishing wilderness in the US, Foreman established a group under the banner No compromise in defense of the earth. Unlike other environmental groups working within the system to achieve change, EF! adopted tactics outside the law, espousing monkey wrenching and direct action. EF!, which has since disavowed the practice, spiked trees to discourage logging (a spiked tree can cause serious injury to a logger whose chain saw meets with unexpected metal).

In 1989, Foreman and three other EF! members were arrested by the Federal Bureau of Investigation (FBI) on charges of conspiracy to blow up a dam. The FBI had infiltrated the group and all discussions of explosives had originated with the FBI agent. The EF! members were acquitted.

Other EF! activists have experienced similar suspicious acts and violent sabotage. Pacific Northwest anti-logging activist Judy Barry was blown up in her car. She survived, but was seriously disabled. She maintained until her death years later that she had not been transporting the explosives as claimed by the authorities.

EF! continues to attract primarily young eco-activists. EF! is currently active in 13 countries. The group disavows hierarchies and conventional organizational structure. Its UK web page proclaims, EF! has no central office, no paid workers, no decision-making bodies, and is not even an organization in the normal sense of the word.

Its approach has led to a number of similar direct action groups, such as the Ruckus Society.

Ecocentric, Biocentric, Gaiacentric

Ecocentrism is an ideology or worldview that centers on and prioritizes the whole planetary ecosystem as the prime source of value and the proper focus of our attention. The term is virtually synonymous with *biocentric* (centering on the whole biosphere) and *Gaiacentric* (centring on Gaia – the earth, whose systems form one living organism). Such foci distinguish this worldview from *anthropocentrism*, whose humanistic priorities regard human perceptions and interests as the source of all value in nature.

Ecocentric/biocentric/Gaiacentric ideology underlies *deep ecology* environmentalism. Its central ethic assigns intrinsic value to all animate and inanimate elements in the cosmos – value, that is, which would reside in these elements even if human beings were not there to attribute their own values (for instance, economic utility) to nature. Intrinsic value implies that the role of humans is simply that of equal members of the ecological community, with no preemptory rights over other species or other parts of the system. Ecocentrism also emphasizes the importance of balance and interconnectedness in nature and of retaining the unity, stability, diversity, and harmony of all ecosystems.

Ecocentrism reflects the influences of early 12th century organicist philosophy, 19th century Romanticism and anarchism, and of an arcadian tradition in ecological science and in literature. This last is manifest in Aldo Leopold's Land Ethic (1949, *A Sand County Almanack*), which holds that A thing is right when it tends to preserve the integrity,

beauty, and stability of the biotic community. It is wrong when it tends otherwise. Some other ecocentric principles derived from Leopold's land ethic include: everything is connected to everything else; the whole is greater than the sum of the parts (synergy); human and non-human nature are a unity (*see* Leopold, Aldo, Volume 5).

From these principles, and from the notion of a whole ecological community of which animals, plants and humans are all equal members and interdependent parts, it is suggested that the environment has direct rights, that it qualifies for moral personhood and that it is deserving of a direct duty. Ecocentrism then clearly places the environment on a moral par with humans, giving it a biotic right. If applied in practice, such a right would foster environmental protection and preservation over the approach of conservation – the latter implying managed change in accordance with considerations of economic utility. It would also confer legal standing on wildlife and other elements in nature, enabling environmentalists to defend them in court against the damaging effects of potential development, as has happened in the US.

Ecofeminism

Karen J Warren
Macalester College, St Paul, MN, USA

The term ecofeminism was coined in 1974 by Francoise d'Eaubonne to call attention to women's potential to bring about an ecological revolution (d'Eaubonne, 1974). Unlike earlier feminisms, which focused on sex-roles, equal rights, equity in the workplace, educational opportunities for women (e.g., liberal feminism), socioeconomic conditions of women as workers (e.g., Marxist feminism), ecofeminism understands feminism to be a movement to end all systems of domination, including the domination of non-human animals and nature. Since 1974, ecofeminism has surfaced throughout the globe in the form of both women-initiated, grassroots environmental actions and interdisciplinary perspectives on the inextricable interconnections among human systems of unjusti ed domination - both of humans and earth others. The distinctiveness of ecofeminism, then, is that it is a feminist environmentalism and an environmental feminism. Just as there is not one feminism, there is not one ecofeminism. There is no one, uni ed ecofeminist perspective on environmental issues. What ecofeminists have in common is a commitment to the historical interconnections among human systems of domination (including the unjusti ed domination of non-human nature), and to replacing oppressive practices, policies, and philosophies with ones that are not. What makes ecofeminism feminist is its starting point: It begins with women and sex/gender analysis to call attention to the interconnected exploitations and liberations of women, other 'human others' (e.g., people of color, poor people, children, colonized peoples) and 'earth others'. What makes ecofeminism ecological is that non-human animals and nature are integral to the practice and theory of ecofeminism. Ecofeminism not only makes visible the ways in which the well-being of the natural environment is linked to the well-being of diverse groups of humans; it also expands on the notion of a human self as an ecological self. Using insights from both the environmental movement and ecology in the framing of ecologically responsible and sustainable policies, practices and philosophies, ecofeminism has emerged as a political movement among all racial/ethnic, socioeconomic, gendered, and geographical locations.

Ecofeminism is represented by a variety of feminist perspectives and practices. It nds expression in a wide range of (mostly) women-initiated, community activist initiatives around such issues as air and water pollution, biodiversity and cultural diversity, deserti cation and deforestation, indigenous agriculture and food production, toxins and hazardous waste disposal, global warming and acid rain, human overpopulation and habitat destruction, species preservation, development and biotechnology. The slogan of ecofeminism might well be: nature is a feminist issue. At the heart of ecofeminist practice and theory are the various interconnections - historical, causal, empirical, economic, political, scienti c, symbolic and literary, linguistic, conceptual, ethical, religious and philosophical - between systems and practices of domination. As a movement of global environmental change, the main project of ecofeminism is two-fold: to make visible the ways in which the exploitation and destruction of the non-human environment is tied to the exploitation of women, people of color, children, and the poor; and to develop policies, practices, and philosophies which undo and overcome these interconnected dominations. There is literally no area of environmental concern that falls outside the interest of ecofeminist activism and theory. This is not surprising, considering the intimate connections between the health, status, and well-being of the non-human environment and the health,

status, and well-being of women and other 'human others' cross-culturally - now and in the foreseeable future. According to ecofeminists, any plausible, workable, responsible agenda for the 21st century will include ecofeminist insights into and solutions to the globally interlocking systems of exploitation and domination.

EMPIRICAL WOMEN–NATURE INTERCONNECTIONS

Since the starting point of ecofeminism is women, at the outset ecofeminism focuses on women–nature interconnections. But since all women are of some race/ethnicity, socioeconomic status, geographic location, sexual orientation, and marital status, ecofeminism is also about race–nature, class–nature, geographic location–nature, sexual orientation–nature, and marital status–nature interconnections. For simplicity, this essay subsumes these varieties of interconnections under the generic rubric *women- nature interconnections*.

One way to reveal the sorts of concerns that characterize ecofeminism is to consider empirical data on women–nature interconnections. Such data help to clarify why nature is a feminist issue.

Trees

Tree shortages are a problem in many parts of India. Historically, first-world development policies that replaced indigenous, multispecies forests with monoculture eucalyptus and teak plantations solved the problem of too few trees, but in a way that disproportionately affected the livelihoods of local women. Traditionally, women in rural India have gendered responsibilities to maintain domestic economies, which are highly dependent on trees and tree products for food, fodder, fuel, herbs, dyes, medicines, household utensils and building materials, and income-generating activities. Monoculture eucalyptus is unpopular among local women because it provides no food, fodder, herbs, dyes, and medicines and is a problematic fuel. Replacement of indigenous forests with eucalyptus thereby affects women's abilities to maintain household economies, especially when these women also must take on the labor tasks of the local men who move to city areas to work in the eucalyptus plantations.

Food

Women farmers globally grow at least 59% of the world's food; in parts of Africa, women grow 80–90% of the food. Women farmers tend to work longer hours, have fewer assets and lower incomes than men farmers, primarily because their access to credit is limited. Agricultural policies and practices exported from the Northern Hemisphere (the North) to the Southern Hemisphere (the South) often do not recognize the full extent of women's contributions to all aspects of agricultural work (e.g., in plowing, planting, harvesting, weeding, processing and storing crops, and caring for livestock), involve technological improvements which are not aimed at training women or which develop products inappropriate from the standpoint of local women (e.g., solar stoves for women in Africa who cook before dawn and after dusk, or maize shellers that are more time-consuming to use than when women shell by hand).

Water

Less that 50% of the population of the South has a source of potable water or facilities for sewage disposal. Since women and children in the South perform most of the water collection and distribution work, it is women and children who are disproportionately harmed by the presence of unsanitary water. Also, the time spent by women and children in water collection in Africa and Asia (from 5–17 h each week) is time unavailable for other activities (e.g., attending school). Droughts and floods exacerbate the situation. Droughts and floods are among the most serious natural disasters in the South, contributing to desertification, deforestation, and soil erosion on a large scale. But it is poor people, especially women and children, who are most seriously affected by these natural disasters, since they constitute the largest group who live in those areas.

The North also has water-related problems that disproportionately affect women, communities of color, and the poor. The presence of lead and leaking chemicals, as well as the improper disposal of hazardous wastes, has contributed to groundwater contamination of municipal water supplies in all parts of the US. Ground water, the drinking water source for nearly half of the US population, disproportionately affects inner city poor, especially pregnant women, women of color, children, and the elderly, more than other groups.

Toxins

The United Church of Christ's Commission on Racial Justice published an already classic report in 1987 entitled *Toxic Waste and Race in the United States*. The commission found that race is the most important determinant in the location of hazardous waste in the US. Three out of every five African and Hispanic Americans, and more than half of all Asian Pacific Islanders and American Indians live in communities with uncontrolled toxic waste sites. Emelle, Alabama, which is almost 80% African American, houses the nation's largest hazardous waste landfill, receiving toxins from 45 states. Probably the greatest concentration of hazardous waste sites in the US

is on the predominantly African American and Hispanic south side of Chicago. Navajo Indians are the primary workforce in the mining of uranium in the US. However, the dumping of uranium tailings on Navajo (and other American Indian) lands has resulted in higher percentages of health risks (e.g., miscarriages for pregnant women, gynecological cancers, cleft palate and other birth defects) than non-Indian populations.

According to ecofeminism, awareness of these empirical interconnections between the status and treatment of women and other human sub-dominant groups, and the status and treatment of non-human nature, must be part of any informed environmental practice, policy, or philosophy. But ecofeminism doesn't stop there. Awareness of other sorts of women–nature interconnections must also be made visible, addressed, and, where unjustified domination is involved, replaced by life-affirming practices, policies, and philosophies.

ADDITIONAL WOMEN–NATURE INTERCONNECTIONS

These examples provide concrete illustrations of ways in which the exploitation of women is intimately connected to the destruction of the earth. They also make visible why sensitivity to the plights and expertise of women and other human sub-dominants is important to any informed feminism, environmental activism, and environmental policy. But these empirical connections are just one sort of women–nature interconnection of interest to ecofeminists. Consider some of the other ones.

Some ecofeminists have focused on historical interconnections between the domination of women (and other humans others) and the domination of Earth. Ecofeminist philosophers, for example, have been among those who trace patterns of domination to the Western philosophical tradition of rationalism, according to which the mental trait of reason or rationality is both the essence (or hallmark) of humanness and that which elevates (at least some) humans above the inferior, physical, bodily, corporeal realm of nature (Plumwood, 1993). Drawing on the dualisms of mind/body, reason/emotion, culture/nature, that which is associated with mind, reason and culture is claimed to be superior to that which is associated with body, emotion, and nature. In systems of domination, the subordinated others (e.g., women, slaves, children) have historically been identified with the inferior physical world of nature; the justified domination of these other human others' is based on their alleged association with what is biological, natural, bodily, or physical.

Ecofeminist historian Carolyn Merchant provides a different account. Merchant argues that the death of nature occurred between 1500–1700, when an older world order was replaced by a reductionist, mechanistic world view of modern science, which sanctioned the exploitation of nature, unchecked commercial and industrial expansion, and the subordination of women. According to Merchant (1980, 2)

> The metaphor of the earth as a nurturing mother was gradually to vanish as a dominant image as the Scientific Revolution proceeded to mechanize and to rationalize the world view. The second image, nature as disorder, called forth an important modern idea, that of power over nature. Two new ideas, those of mechanism and of the domination and mastery of nature, became core concepts of the modern world.

This change in controlling imagery was directly related to changes in human attitudes and behavior toward the earth. Whereas the nurturing Earth image can be viewed as a cultural constraint restricting the types of socially and morally sanctioned human actions allowable with respect to Earth, the new images of mastery and domination functioned as cultural sanctions for the denudation of nature. According to Merchant, the change in dominant nature imagery from organism to machine permitted the removal of classical moral constraints on how one treats mother nature, a living organism. The mechanistic metaphor thereby helped sanction the exploitation of inert, passive nature as object of study.

These historical interconnections raise important conceptual issues about social systems of oppression and domination, conceptions of the human self, and the nature of human responsibilities to the non-human world. For example, ecofeminist philosophers have provided analyses of fundamental features of oppressive conceptual frameworks that underlie systems of domination (Warren, 1990). A conceptual framework is a set of basic beliefs, values, attitudes, and assumptions about oneself and one's world. It is a historically located, socially constructed thought world – a lens through which one sees and interprets the world. When a conceptual framework is oppressive (e.g., a sexist, racist, or classist conceptual framework), the beliefs function to justify the unjustified domination of the other (e.g., women, people of color, the underclass).

There are five noteworthy features of an oppressive conceptual framework: (a) value-hierarchical, up–down, thinking; (b) oppositional and mutually exclusive value-dualisms (*either- or* thinking); (c) conceptions of power which advantage the power of ups over downs; (d) conceptions of privilege which systematically advantage the ups over downs; and (e) a logic of domination: a moral premise which justi es the subordination of downs by ups on the grounds that the ups have a morally relevant trait which the downs, as downs, lack. Whether the conceptual framework is sexist, racist, classist, heterosexist, colonialist, or ethnocentric, insofar as they are oppressive conceptual frameworks, these ve features seem to be shared in common (Warren, 2000).

These basic conceptual interconnections among social systems of domination are important to ecofeminist philosophy. Oppressive conceptual schemes justify relationships of domination and subordination through a logic of domination, which asserts that whatever is up deserves to be up and is morally justified in treating as inferior whatever is down. When women, people of color, the poor or children are downs in *up down* relationships of domination and subordination, their justified subordination often has rested historically on their alleged association with the inferior, non-mental realm of animals and nature. In this way, sexism is conceptually tied to *naturism*, i.e., the unjustified domination of animals and non-human nature.

There are two basic ways this conceptual link occurs. First, sexism and naturism are linked through an oppressive conceptual framework characterized by a logic of domination. Since all feminists must oppose the logic of domination (required by patriarchal arguments for sexism), and since the arguments for the domination of non-human nature presuppose the same logic of domination, all feminists must oppose the arguments for the domination of non-human nature. The logic of traditional feminism thereby requires extending feminism beyond a concern with sexism, or even a concern with all forms of human subordination, to a concern with naturism; naturism must also be included about the systems of domination that feminism opposes (Warren, 1990).

The second conceptual reason sexism and naturism are linked has to do with the concepts of gender and nature. The concept of gender is socially, historically, and materially constructed. Both the concept *women*, and the identities of particular women, are constructed from and reflect such factors as race/ethnicity, class, age, affectional orientation, ability, geographic location, and religion; to be a woman is to be a woman of a certain race/ethnic, class, age, affectional orientation, ability, geographic location, and religion. This means that there is no pure gender; gender always occurs in conjunction with race, class, age, affectional orientation, geographic location.

Similarly, the concept of nature is socially and humanly constructed; it is not a fixed, static, self-evident, given or absolute concept. What is meant by nature, and even what counts as a natural object for humans, is constructed from and reflect such factors as the race/ethnicity, class, age, affectional orientation, geographic location, and religion of humans who name, describe, judge, understand, and interact with nature. The meanings of nature are constructed out of human values, beliefs, attitudes and assumptions – different and differing human conceptual frameworks.

Obviously, the claim that women and nature are social constructions does not deny that there are actual humans and actual non-human natural entities. One can hug a human, climb a tree, swim a river, cultivate a plant, destroy an ecosystem, or enjoy being in nature. These entities (e.g., humans, trees, nature) are physical realities. But what is meant by human, tree, or nature, and what constitute the identities of humans, non-human natural entities, and nature are social realities as well. These social realities are social constructions. What constitutes country for Australian aboriginal peoples is not what Europeans mean by country, land, landscape, property, or wilderness. In the words of anthropologist Deborah Bird Rose, the closest European and American-derived expression is nourishing terrain, a place that gives and receives life. Not just imagined or represented, it is lived in and lived with. Country is sacred, alive, conscious, the law, place, managed, owned, land. Country knows, hears, smells, takes notice, takes care, is quiet, dangerous, lonely, sorry or happy or sad, is healthy, sick, or not so good. Country is criss-crossed with song lines and the tracks of the Dreamings: walking, slithering, crawling, flying, chasing, hunting, weeping, dying, giving birth (Rose, 1996, 35). The relationships between people and their country is a a kinship relationship, and like relations among kin, there are obligations of nurturence. People and country take care of each other (Rose, 1996, 49).

Such linguistic differences about what something is called are important to ecofeminism. As many philosophers (e.g., Wittgenstein) have argued, the language one uses is deeply embedded in conceptions of oneself and one's world – one's conceptual framework. When that language is sexist or naturist, it reflects and reinforces conceptions of women and non-human nature as inferior to, having less status, value, or prestige than, that which is identified as male, masculine, or human (i.e., male).

Such is the case with the language used historically in Western societies to describe women and nature. Women are described in animal (nature) terms as pets, dogs, cats, pigs, cows, sows, foxes, chicks, serpents, bitches, beavers, mares, old mares, old bats, old hens, mother hens, pussies, pussycats, cheetahs, bird-brains, hare-brains, elephants, and whales. Language that animalizes or naturalizes women in a patriarchal culture where animals are seen as inferior to humans (men) thereby reinforces and authorizes women's inferior status. Similarly, language that feminizes nature in a patriarchal culture where women are seen as subordinate or inferior reinforces and authorizes the domination of nature. Mother nature is raped, mastered, conquered, mined, controlled, poked, prodded, and pried into; her secrets are penetrated and her womb is put into service by the man of science. Virgin timber is felled, cut down; fertile (not virile) soil is tilled and land that lies fallow is barren (not impotent) and useless, like a woman who cannot conceive a child. The exploitation of nature and animals is justified by language which feminizes them; the exploitation of women is justified by language which naturalizes women.

Just as the justification for the dominations of women and non-human nature is reinforced by sexist–naturist language,

so too the justification for the domination of people of color is reinforced by racist-naturist language. For example, in the US, the justification for dominating African American men was bolstered by language and images of sub-dominant children, animals, and nature. Slaves were mere brutes, animals, dogs, coons, apes. African American men were denied the rights of citizenship as a subordinate and inferior class of beings, who had been subjugated by the dominant race ••• (Stone, 1974; n 19). The legal status of slaves as things, mere property or chattel was accepted law in the 1850s.

Languages of domination are crucial to effective implementations of the logic of domination by colonizers. Standard European and Anglo-American land-use attitudes and descriptions of wilderness involve the peculiar notion that if one cannot see traces of one's own culture in the land, then the land must be natural or empty of culture (Rose, 1996). Terra nullius (land that was not owned) was the official doctrine of (white) Australia until overturned by the High Court's Mabo Decision in 1995. That decision marks the first time Aboriginal and Islander people's occupation and ownership of country was formally and publicly acknowledged.

The view that land with no ownership is uninhabited wilderness is familiar in the US as well. Wilderness is often conceived as wild, idle, worthless frontier until tamed and cultivated through the white settler's agriculture. Land that just lies there, barren, useless, uncultivated, for example, untouched virgin prairie, has no value until domesticated by the white man's plow. White racism is not just a social construct around skin color and ethnicity; it is also an ecological construct, one that reflects and reinforces ecological as well as social factors.

Many ecofeminists argue that cultural transformation must occur if these interlocking systems of domination are to be eliminated. Since historically there are important symbolic interconnections between the domination of women (and other human others) and the domination of non-human nature, one must examine a culture's images, rituals, rites, ceremonies, stories, myths, songs, literature, theologies, religions and spiritual practices.

Some ecofeminists have examined the religious and theological symbols that affect our cultural views about humans and nature. For example, ecofeminist theologian Elizabeth Dodson Gray argues that the Christian biblical tradition is a hierarchical order of creation, a pyramid of dominance and status, where woman comes after and below man, children come after women, and pets, animals, plants and nature itself follow, in descending order of status and worth. Gray argues that we need to think ourselves out of such a patriarchal conceptual trap by revisioning a theology of creation that is not a hierarchical pyramid of dominance and subordination (Gray, 1979).

Other ecofeminists (spiritual ecofeminists) agree with Gray. Despite their very vocal critics, including ecofeminist critics, spiritual ecofeminists (e.g., Spretnak, 1982) argue that non-patriarchal, earth-based spiritualities are not only necessary to any healing relationship between humans and the earth, but to any liberatory ecofeminist politics. The politics of women's spirituality must be a Green politics.

Some ecofeminists turn to literature, particularly women's nature writing, to affect a cultural transformation. Paula Gunn Allen, Margaret Atwood, Rachel Bagby, Annie Dillard, China Galland, Sally Gearhart, Susan Griffin, Linda Hogan, Winona LaDuke, Ursala Le Guinn, Marge Piercy, Leslie Marmon Silko, Alice Walker, and Terry Tempest Williams are just a few of the women who have explored these interconnections through their stories, poems, novels, and essays. Ecofeminist literature is important because cultural images reflect not only who we are but help shape who we become. Attitudes toward animals, plants, mountains, rivers – what Leopold (1949) refers collectively to as *the land* – reflect deeply seated values about culture, nature, wilderness and the wild, and human nature. Some nature writers romanticize and uncritically idealize wilderness. Others imagine a wild landscape inhabited by humans who occupy a unique place as co-members of the ecological community. Still others challenge the very concepts of nature and wilderness, and the historical construction of a nature/culture dualism, which puts (some) humans in oppositional superiority over nature. The emerging field of ecofeminist literary criticism examines the political dimensions and ramifications of these concepts within ideologies of domination, while seeking to develop literature and criticism that emphasizes appropriate and edifying human relationships within the ecological community.

When one challenges cultural sources of systems of domination, epistemological claims also get challenged. Whose knowledge? and Knowledge according to whom? become important questions, since ecofeminist theory and practice always examines the social context in which epistemological claims are generated. Women in the so-called developing world who have gender responsibilities for managing forests, for example, may have invaluable technical knowledge about multiple uses of trees, based on their hands-on, daily, lived experience as forest managers. Their experiential ways of knowing – their epistemology – may challenge mainstream, Western conceptions of the objectivity, value-neutrality, and impartiality of genuinely scientific knowledge claims.

Epistemological worries often interact with psychological ones. Ecofeminist sociologist Ariel Salleh, for example, challenges ethical and epistemological positions that embody a distinctly masculine sensibility, which desires to transcend nature and culture. Salleh argues that since ecofeminism reveals the patriarchal conceptual foundation

of the continued destruction of the natural environment, what is needed is that the unconscious, psychological connection between women and nature needs to be made conscious, and the hierarchical fallacies of the great chain of being acknowledged, in order for any real growth towards a sane, humane, ecological future (Salleh, 1984).

Given the nature of some of these interconnections between the treatment of women and the treatment of non-human nature, it is not surprising that perhaps the most visible ecofeminist theory and activism has been in the political arena. Conferences, workshops, direct actions, and grassroots organizing around environmental issues have been initiated globally by a new radical core of low-income women environmentalists. These women are motivated by the irrationalities of capital-intensive growth and the destruction of their domestic economies. Whether it is the Chipko movement in India, the Women's Pentagon Actions in the US, the Seminar on Ecofeminism at the United Nations Conference on Environment and Development in Rio de Janeiro (1992), or the varieties of global women-initiated actions for better health care, reproductive rights, and environmentally safe neighborhoods, ecofeminist activism has an international presence as a distinctly feminist and environmental movement.

Lastly, much of the scholarly literature of ecofeminism has focused on environmental ethics. Minimally, the goal of ecofeminist ethics is to develop theories and practices concerning humans and the natural environment that are not male-biased and which provide a guide to action in the pre-feminist present. This has involved the development of a variety of ecofeminist ethical positions and practices, where notions of care, loving perception, friendship, sharing, appropriate reciprocity, and kinship emerge as morally relevant and important values. One needs only to look at the range of ecofeminist positions regarding such practices as factory farming, vivisection, worldwide traffic in wild animals, violence toward women, health care, reproductive technologies, the location of hazardous waste, and environmental conservation and preservation to see the impact of ecofeminist moral theory in moral practice.

Since its inception as a distinct feminism, environmentalism, and form of feminist practice in 1974, ecofeminism has emerged as an important, timely, powerful movement at local, national, international, and global levels. As a social and political movement, ecofeminists have taken the lead in exploring the roles of science, development and technology in the development of environmental policies (e.g., on biodiversity, global warming), practices (e.g., the development of biotechnologies), and decision-making structures (e.g., for implementing Agenda 21), which make the expertise of women and indigenous peoples central to both the analysis and resolution of pressing environmental problems. Ecofeminist activism has produced change through numerous kinds of action, including direct action, civil disobedience, strikes, boycotts, demonstrations, lobbying, and other more traditionally recognized forms of political action (Sturgeon, 1997). Ecofeminist activists have engaged in coalition building among and across different constituencies (e.g., peace, environmental, women's, anti-racism, anti-colonialism, animal rights movements). And ecofeminist activists have raised awareness about the interconnections among all political and economic structures of domination and exploitation.

As a theoretical position, ecofeminist scholarship has broadened and deepened Western and non-Western views in such different arenas as the arts, economics, ethics, geography, history, literature, philosophy, politics, religion, sociology, and science. It has helped shape a new sense of our human selves as ecological, relational selves who are both similar to and different from non-human nature in distinct and important ways. It has been a leader in the environmental justice movement, and has helped white Western feminism to expand its self-conception to recognize not only the interconnections among forms of human domination and liberation based on gender, race, class, affectional orientation, age, and geographic location, but among these and the domination and liberation of non-human animals and nature.

Perhaps the most important theoretical contribution of ecofeminism is simply the starting point of its environmental analysis: using concrete empirical data and women's felt, lived experiences to show the very real interconnections between the plight of women, other human others, and the domination of non-human nature. This starting point makes any adequate theory or practice of feminism, environmentalism, or human liberationism intimately and inextricably interconnected.

The remarkable cross-cultural flourishing of ecofeminism internationally since d'Eaubonne (1974) coined the term is testimony to its power and promise. Ecofeminism is visible in the practical, policy, and theoretical spheres. It is grassroots, multiracial/multiethnic, local and global. It is action-oriented, giving voice to local women-initiated environmental practices. It is forward-looking and transformative in focus, moving us beyond harmful social systems of domination, which endanger all life on earth. According to ecofeminism, any feminism, environmentalism, or environmental policy which fails to include ecofeminist insights into the unjustified and interconnected dominations of women, other human others, and non-human nature will simply be inadequate for the needs of the 21st century.

Eco-socialism

Eco-socialism is a radical homocentric application of socialist analysis and prescriptions to environmentalism. It also modifies traditional socialism to take account of environmental issues and perspectives. Its critical analysis of history, social change and economics draws particularly on Marx's (early) writings, especially as interpreted by William Morris. Its prescriptions often revive utopian socialist traditions of decentralization, direct economic democracy, communal ownership of the means of production, etc. Hence the brand of socialism represented is close to anarchist-communism, although there are some major differences between eco-anarchists and eco-socialists concerning analysis and strategies. Eco-socialism's historical materialist analysis locates the causes of contemporary environmental abuse in the workings of the economic mode of production of capitalism, and the institutions and world view necessary to its functioning. Eco-socialism argues that environmentally unsustainable development is inherent to capitalism, therefore to end the former, the latter must be abolished and replaced by socialism. In socialism, it is argued, people can end the alienation from nature and from each other that causes environmental degradation, yet production and industry in pursuit of Enlightenment Project ideals could continue. Such production, with distribution, would be rationally planned – perhaps by an enabling state, or, in more anarchistic visions, by bodies representing federation of local communities and regions.

Eco-socialist society would rediscover and express our real relationship to nature – neither separation and superiority, as contemporary capitalism presupposes, nor of mere equality, as ecocentrism believes. Rather, society and nature are dialectically related, so that each is a manifestation of the other. Nature is socially produced, and what humans do is natural. Socialist communities would recognize that they are not intrinsically determined by nature's limits, as deep ecology believes. But they are likely to want to steward,

protect and wisely manage relationships with nature, for the benefit of all community members.

DAVID PEPPER *UK*

Ecosystem Approach

What constitutes valid science and a valid scienti c method? That question has never been fully resolved to the satisfaction of every informed scientist who has employed a scienti c method that had been duly legitimated within some network of expert and responsible peers. There have always been critics to challenge any claim that some particular kind of science was the correct or the best one. Perhaps a view shared most widely among scientists is that honest and modest skepticism is a necessary ingredient within science. An opposing view might be termed fundamentalist.

The concept that species including humans have emerged historically within evolution, in which natural selection plays a strong role, was presented scienti cally by Charles Darwin and others in the mid-19th century. Some Christian scholars took exception to the whole notion of natural evolution. Skeptical scientists and theologians may enjoy debating but fundamentalistic scientists and theologians clash.

The con ict within science concerning evolution is not as well known as that between some scientists and some theologians. In the mid-19th century the physicists and chemists were using experimental methods in laboratories to discover many laws of nature. These scientists preferred to view the world and cosmos as a kind of clockworks in which every phenomenon had a prior cause; cause effect linkages could be described and explained fully in linear deterministic terms. In principle, a fully informed scientist could draw diagrams, de ne terms, write formulae and insert numbers that altogether explained something completely. Such a scientist could achieve conceptual closure, which presupposed that nature itself was closed to seminally new happenings.

But the concept of evolution implied that nature was open to the emergence of new species, say. So some aspects of nature must remain open even though linear laws like those of Isaac Newton, which appear to be deterministic, may also play a role. Are universal laws only partially successful in constraining the contextual processes apparent in evolution? Or may there be ways of perceiving contextual phenomena that are consistent with universal laws, or *vice versa*? Generally, should a scientist start with accepted linear universal laws and then study apparent non-linear exceptions in particular contexts, option A. Or should he/she start with non-linear contextual speci cs and try to infer quasi-linear universal generalities, option B? Perhaps a dialectical approach can be taken in an attempt to be fair to both options. Eventually some scientist may nd or has found a way to synthesize and transcend such a debate.

The concepts of ecology, ecological systems and ecosystems arose within geological, biological and geographic studies that addressed the tension between these two mindsets, or what Magoroh Maruyama calls *mindscapes*. Thus Ernst Haeckel, a contemporary of Darwin, worked at the interface of evolution through natural selection and an approach that has come to be called *environmental determinism*. Later ecologists such as Arthur Tansley deliberately chose option A, more or less. Other ecologists such as Frederick Clements chose option B. An early stage of a synthesis may now be emerging with a focus on complexity as in the innovations of Lynn Margulis, James Lovelock and many others, option C. Each approach continues to have its protagonists entering the 21st century, though the ranks of option C appear to be swelling at the expense of options A and B.

According to this simplistic classi cation, three somewhat different versions of *ecosystem approach* can now be encountered in the scienti c and popular literatures that focus on biological phenomena. Within much of contemporary biology there may still be an underlying presupposition that the disciplined, disinterested scientist can make objective observations, conduct logically correct analyses and infer valid generalities about some features of reality. Such a presupposition may be termed *deterministic* or *positivistic*. Thomas Kuhn apparently intended his notion of a paradigm to relate to a properly justi ed inference obtained by using an approach based on such a presupposition.

On the other hand, these terms, and especially ecosystem approach, are coming to be used with perceived phenomena that include what is formally biological and much more. Some include global atmospheric and hydrological processes, the current manifestations of which are strongly dependent on historical biological events. Or cultural economic and governance processes may be included. An ecosystem approach may even be invoked with respect to cosmogenesis, or the evolution of the cosmos during the past 10+ billion years. With some of these wider applications of the term, positivistic presuppositions may be replaced by a set of constructivist presuppositions that relate primarily to the working hypotheses within a network of scienti c peers and not to some prior notion of external reality. Within such a mindscape, a particular version of an ecosystem approach may be perceived as a dynamic movement rather than a Kuhnian paradigm.

Within current governance processes related to environmental issues, a linear deterministic version, as in option

A, may still be found in some research and management, related to utilitarian interests in natural resources, say. Option B may dominate with preservationist interests as in biodiversity. Option C may dominate in studies and practices concerning natural/cultural systems in which the residents are committed to a policy of responsible reciprocity or caring sharing among all the kinds of creatures, as with the role of Aboriginals in environmental matters. Innovators with an option C kind of ecosystem approach may find useful roles for contributions by option A and B kinds, so long as the latter do not act to prevent their transcendence as in option C.

Ecosystem Services

Ecosystem services are the goods and life support functions provided by natural ecosystems and their species that sustain and fulfill human life. Ecosystem services are the profit that we as humans reap from the Earth's natural capital.

Table 1 Ecosystem services and functions adapted from Costanza *et al.* (1997) with permission from *Nature* (http: //www.nature.com/)

Ecosystem services	Examples
Regulation of atmospheric chemical composition	Carbon dioxide (CO_2)/oxygen (O_2) balance, O_3 for UVB protection and SO_x levels
Regulation of global temperature, precipitation, and other biologically mediated climatic processes at global or local levels	Greenhouse gas regulation, DMS production affecting cloud formation
Capacitance, damping and integrity of ecosystem response to environmental fluctuations	Storm protection, flood control, drought recovery and other aspects of habitat response to environmental variability mainly controlled by vegetation structure
Regulation of hydrological flows	Provisioning of water for agricultural (such as irrigation) or industrial (such as milling) processes or transportation
Storage and retention of water	Provisioning of water by watersheds, reservoirs and aquifers
Erosion control and soil retention within an ecosystem	Prevention of loss of soil by wind, runoff, or other removal processes, storage of stilt in lakes and wetlands
Soil formation processes	Weathering of rock and the accumulation of organic material
Storage, internal cycling, processing and acquisition of nutrients	Nitrogen fixation, nitrogen, phosphorous and other elemental or nutrient cycles
Recovery of mobile nutrients and removal or breakdown of excess or xenic nutrients and compounds	Waste treatment, pollution control, detoxification
Pollination and movement of floral gametes	Provisioning of pollinators for the reproduction of plant populations
Biological control (trophic dynamic regulations of populations)	Keystone predator control of prey species, reduction of herbivory by top predators

(*continued overleaf*)

Table 1 (*continued*)

Ecosystem services	Examples
Refugia; suitable habitats for resident and transient populations	Nurseries, habitat for migratory species, regional habitats for locally harvested species, or overwintering species
That portion of gross primary production extractable as food	Production of fish, game, crops, nuts, fruits by hunting, gathering, subsistence farming or fishing
That portion of gross primary production extractable as raw materials	The production of lumber, fuel or fodder
Sources of unique biological materials and products	Medicine, products for material science, genes for resistance to plant pathogens and crop pests, ornamental species (pets and horticultural varieties of plants)
Providing opportunities for recreational activities	Eco-tourism, sport fishing and other outdoor recreational activities
Providing opportunities for cultural and other non-commercial uses	Aesthetic, artistic, educational, spiritual and/or scientific values of ecosystems

Ecosystem services range from regulation of the chemical composition of the atmosphere, to water supply to pollination to recreation. Prugh (1995) categorizes these services into four main areas, regulation, carrier, production, and information services. *Regulation services* are provided, for example by the atmosphere in protecting the Earth's inhabitants from meteorites, and filtering UVB radiation. Ecosystem processes such as atmospheric chemical composition, climate, water, nutrient cycling, soil and wastes are also regulated by nature for life to exist on Earth. *Carrier services* from nature provide the space and a suitable substrate for humans to live and play, and as a habitat for all of the Earth's plants and animals. Nature provides *production services* by supplying the oxygen, water, food, medicines, raw materials and other resources to humans and other living creatures. And *information services* provided by nature include aesthetics, artistic inspiration and scientific education and information.

Table 1 adapted from Costanza *et al.* (1997) lists a variety of ecosystem services.

Emergy

Emergy is a term developed by Howard T Odum (Odum, 1986, 1996) for use in environmental and economic accounting. Odum has been an important contributor to energetic analysis of ecosystems and has a long history of applying energy analysis to questions of environmental and human well-being (Odum, 1971). Emergy measures both the work of nature and of humans previously required, directly and indirectly, to generate a product or service. While natural ecosystems run on current flows of solar energy moderated by storage systems with fairly rapid turnover, the human economy also draws heavily on very long-term solar storage in the form of fossil hydrocarbons and has begun to tap nuclear energy. Odum does not ask how much energy it took to produce the fossil fuels or nuclear energy, but he does argue that the net energy, the difference between the energy in the resource and the energy required to mine, transport, and process the resource into a usable form, is the important measure. Odum argues that all energy should be converted to solar equivalents, or *solar emergy*, for accounting consistency and because of the dominant role of the sun.

Odum (1971) believes that there is a fourth law of thermodynamics which he has labeled the maximum power principle, or more recently the *maximum empower principle*. In the competition among self-organizing processes, network designs that maximize empower' will prevail (Odum, 1996). Thus, he argues that by selecting choices that maximize emergy production and use, policies and judgments can favor those environmental alternatives that maximize real wealth, the whole economy, and the public benefit (Odum, 1996). Odum and his co-researchers have used emergy analysis to explore specific issues such as the relative desirability of different fuels, to broad questions such as the sustainability of alternative modes of development.

Howard Odum has established a school of energy analysis with a sizeable number of followers, largely trained with Odum, who advocate that emergy analysis should replace, or at least complement, other forms of analysis, especially economic analysis as currently practiced. Critics argue that energy flows do not fully characterize all of the critical aspects of environmental systems, that human values cannot be reduced to energy determinism, and that it is highly unlikely that society will eliminate the diverse institutions through which decisions are currently made, and reduce the power of those interests supporting current institutions, and replace them with institutions for emergy analysis. At the same time, the insights from emergy analysis may prove sufficient to extend existing institutions so as to incorporate yet another approach and reduce somewhat the dominance of economic interests and reasoning.

Encyclopedias: Compendia of Global Knowledge

Peter Timmerman
University of Toronto, Toronto, Canada

" ••• to collect all the knowledge scattered over the face of the earth, to present its general outlines and structure to the men with whom we live," was Diderot's description of his purpose in the Encyclopedie ou Dictionnaire Raisonne des Sciences, des Arts et des Metiers *(1751- 1772). This encyclopedia was the symbol (and a central driving force) in the French Age of Enlightenment, and had at least two purposes: to wrestle knowledge free from the hierarchical institutions that held onto it as a source of their power and prestige; and to promote the idea that reason could penetrate into every aspect of human activity. Among the most famous articles in the encyclopedia were those on the arts and crafts, including du Quesnay's path-breaking work on the systematic analysis of land as the basis of economic development.*

The growth of encyclopedias in the 18th century (including the earlier *Chambers Cyclopaedia, or Universal Dictionary of Arts and Sciences* (1728), the immediate forerunner of the *Encyclopedie*, and the later British (Scottish) *Encyclopedia Britannica* (1768–1771) fostered by Andrew Bell, can be seen as the expression of a number of different forces at work. First, there was a powerful sense that the emerging sciences of the previous 100 years were beginning to generate substantial amounts of new knowledge that needed to be synthesized for a general reading audience. Second, there was an emerging new middle class in Europe who had – or could be persuaded to have – a need for enlightenment. Third, both Britain and France were now extensively involved in exploration and colonial developments that were beginning to encompass the entire globe.

When Germany became a colonial power, and an aspirant to global power, it too generated its lexicons and the classic Lobel-Brockhaus encyclopedias.

The vast *Soviet Encyclopedia* (1926–1947 and later editions) is a famous example of the symbolic power of encyclopedias, since the creation of the Encyclopedia unfortunately coincided with a whole sequence of ups and downs in official versions of everything, and caused innumerable headaches (and not a few dangers) for compilers and revisers through the years. This was in the grand tradition of Diderot's earlier work, in which a number of entries had to be penned anonymously.

Behind these specific creations, there also lurks the perennial dream of having all knowledge at one's fingertips (and possibly the whole world under one's command). As Collison (1966) notes, it was Francis Bacon (1561–1626) who wanted to re-organize all human knowledge into a 130-part hierarchical study divided into main areas (external nature, Man, and Man's actions upon nature), below which would be sub-areas, and so on. The impulse behind this was, in a sense, to discern or bring order into a world whose previous structural meaning (the medieval Christian world view) had been profoundly shaken.

The potential structure, topics, and outlay of encyclopedias have (since Bacon) been the subject of many tendentious discussions (McArthur, 1986), ranging from whether alphabetizing entries (neutral, handy, but unimaginative) is best, to the potentially infinite possibilities being envisaged (and beginning to be created) by online storage and retrieval systems.

The explosion of knowledge has not been matched, but has certainly been accompanied, by an explosion of specialized encyclopedias in music (Grove), the social sciences (Seligman), and innumerable science encyclopedias, dictionaries, lexicons, etc. Virtually all of them wrestle with the same issues: comprehensiveness versus selectivity; organizational structure; issues of balance; timeliness, accuracy, appropriate assessment.

Global environmental change represents a significant challenge to the encyclopedist, for all the reasons cited above. The impulse to assess that change has perhaps been best captured in the series of books spanning over a century inspired by George Perkins Marsh *The Earth As Modi ed by Human Action* (1885, first published as *Man and Nature*, 1864), most recently *The Earth As Transformed By Human Action* (Turner, 1990), which, if not absolutely encyclopedic, are at least inspired by the possibility of a great global perspective on our situation. Similarly, there are extensive international scientific and social scientific projects whose products could be seen as informal encyclopedias of global environmental knowledge.

There are post-modern voices that consider encyclopedias and similar projects to be significant examples of the total globalizing mentality of the continuing enlightenment project, that is, the use of homogenized and rationalized information as a tool for power. Others – of whom this author is one – rather remember days as a child sitting in a deep armchair with a huge volume of some encyclopedia, diving into distant worlds I might never visit. Encyclopedias are probably still big enough to serve both purposes, and others.

Enlightenment Project

The *Enlightenment* was an 18th century European philosophy emphasizing reason and individualism rather than tradition. The attempt to apply scientific rationalism throughout human knowledge is sometimes termed the *Enlightenment Project*. This term has come to represent all the ideals associated with the modern period of the 18th to 20th centuries. These ideals form a grand narrative which is optimistic about human history, seeing in it the working out of progress – particularly in terms of increasing material welfare and universal justice – in which all of humanity can share.

This is to be achieved partly through scientific and technological advancement, following Francis Bacon's creed that scientific knowledge equals power over nature, and that this power is to be used for the benefit of Man's estate, freeing all humanity from scarcity and protecting it from nature's caprices. Additionally, the Enlightenment Project would emancipate societies from the irrational yolk of myth, religion and superstition, by deriving moral and legal principles from rational thought alone. Such principles – e.g., the universal declaration of human rights, social justice, sanctity of human life, freedom of speech, equality of opportunity and/or outcome – should be applied everywhere.

This thinking has formed the basis for the spread of Western-style values, including democracy and capitalism, in global modernization. Ostensibly, it champions rational enquiry as the basis for all knowledge, together with the beliefs that only intellectual progress could bring world order and happiness, and that objective science and universal morality and law are attainable as David Harvey says in his 1989 book, *The Condition of Postmodernity*, the Enlightenment Project s axiom was that there was only one possible answer to any question. Postmodernists now challenge this on empirical grounds that the pursuit of grand narratives made the 20th century in particular one of massive and widespread human oppression and suffering.

Environment and Violent Conflict

see The Environment and Violent Conflict (*Opening essay*, **Volume 5**)

Environmental Defense Fund

One of the United States rst and most respected environmental groups, *Environmental Defense Fund* (EDF) was founded in 1967 by residents of Long Island, NY, who were pressing for a ban on the pesticide dichlorodiphenyltrichloroethane (DDT). In 1972, EDF members felt that their efforts, and those of others, were rewarded by the decision by the US government to ban DDT. From EDF s small origins, it grew quickly within the United States. (It has no international branches). By 2000, it had over 300 000 members and 170 professional staff members, including more than 75 full time scientists, lawyers and economists. EDF headquarters are in New York City, but it has substantial of ces in Washington, DC, and seven other US cities. Its 1998 budget was $27.8 million.

The organization s hallmark is professionalism. Its members provide nancial support, but are not engaged in governance nor are they active participants in election campaigns. In terms of its organizational niche, EDF represents policy research and the extolling of market mechanisms to nd environmental solutions. As a caricature of organizational culture, if Greenpeace hangs banners from smoke stacks, Earth First! spikes trees, and Sierra Club lobbies congress, EDF is in the boardroom. EDF s Alliance for Environmental Innovation, in collaboration with Pew Charitable Trusts, represents one of the only environmental organizational efforts at direct engagement with private corporations to facilitate higher environmental corporate performance.

EDF has actively promoted such solutions as emissions trading, both to address local air pollution problems as well as a global approach to reduce greenhouse gases. EDF continues to be active on issues of chemical releases and recently targeted the pollution problems created by expanding intensive livestock factory farms.

ELIZABETH MAY *Canada*

Environmental Economics

Environmental economics addresses how environmental problems arise, how market mechanisms can be used to improve environmental quality, and the level of quality that most ef ciently balances preferences for material goods and for environmental services (*see* **Ecological Economics**, Volume 5).

From the perspective of neoclassical economic theory, environmental problems exist because markets for environmental quality are incomplete or totally absent. Markets fail because rights to the services of the environment are unclear or cannot be assigned to individuals and must be held in common. One person cannot obtain cleaner air without everybody obtaining cleaner air, so clean air cannot be sold to individuals and must be obtained collectively. Government action is justi ed by market failure, and environmental economics addresses what governments should do.

Economists argue that markets maximize the difference between the bene ts and costs of providing a good. Environmental economists thus argue that the level of environmental quality should be determined so as to also maximize the differences between the bene ts and the costs. The costs of obtaining environmental quality are typically relatively easy to measure for they are the value of the market goods forgone to install pollution control equipment or take other steps. Environmental valuation is the art and science of estimating the bene ts that do not have market equivalents. Valuation techniques include looking at defensive and corrective expenditures that could be avoided if environmental quality were improved, analyzing how differences in environmental quality affect land values, deducing from individual behavior what people would be willing to pay,

and simply asking people what they would be willing to pay for improved environmental quality. The efficient level of pollution is achieved when the additional costs of clean-up just equal the additional benefits.

The dominant approach is to regulate the level of pollution allowed by each polluter, adjusted for size or output of the production unit. Environmental economists, however, argue that it is more efficient to determine the appropriate level of total pollution, distribute this right among polluters, and then allow polluters to trade pollution rights. With tradable permits, polluters who can reduce pollution more cheaply do so and sell their permits to those whose costs of pollution reduction are high (*see* Tradable Permits for Sulfur Emission Reductions, Volume 4). This results in an efficient reduction of pollution in that the level of environmental quality sought is achieved at the least cost. Alternatively, this same efficient result could be achieved by taxing pollution or subsidizing pollution reduction.

Environmental economics also addresses the harvesting of biological and other renewable resources and the mining of minerals, or non-renewable resources, over time. The rate of interest plays a central role in the efficient rate of use, along with the rate of reproduction or replenishment for renewable resources, and the expected future demand for the resource. For both renewable and non-renewable resources, the pattern of use over time that maximizes net present value is the economically efficient rate of use (*see* Discounting, Volume 5).

RICHARD B NORGAARD *USA*

Environmental Ethics

J Baird Callicott
University of North Texas, Denton, TX, USA

An environmental ethic is a set of behavioral rules, or a set of principles or precepts for governing human behavior toward the natural environment. Environmental ethics may mean more than one such ethic - that is, simply the plural of environmental ethic. More usually it refers to the philosophical subdiscipline devoted to constructing and justifying an environmental ethic. This article is about environmental ethics in both senses. It reviews a number of the most notable environmental ethics that philosophers have recently constructed and tried to justify and thus it surveys the new philosophical subdiscipline devoted to that enterprise.

In response to a popular perception of an environmental crisis in the late 1960s, the two words in the title of this article were rst put together early in the next decade. Environmental ethics (the philosophical subdiscipline) made its debut as a formal area of study with a college course in the subject at the University of Wisconsin, Stevens Point in 1971. It gradually developed and solidi ed in 1979 with the advent of Environmental Ethics, *the journal which has been continuously published ever since. During the 1980s, anthologies, monographs and textbooks in environmental ethics began to appear. During the 1990s, several more journals devoted to environmental ethics began publication and the literature in the eld continues to grow exponentially.*

In retrospect, an earlier informal environmental ethics literature can be identi ed. Doing so is to some extent a matter of philosophical bias and taste but the following authors would probably be recognized as seminal by all authorities: White (1789); Thoreau (1854); Marsh (1864); Muir (1916); Leopold (1949) and Carson (1962). The concept of an environmental crisis was probably seeded in the Zeitgeist by a popular book, The Quiet Crisis, *by Udall (1963), US Secretary of the Interior in the John F Kennedy administration. (The loud crisis was presumably the Cold War threat of nuclear holocaust). Also in uential was* The Closing Circle *by Commoner (1971).*

What happened to precipitate a quiet environmental crisis seems to have been this. In the spirit of beating swords into plowshares, technologies developed for warfare during the 1940s were adapted for peaceful use in the age-old human war against nature. The high combustion air polluting engines developed to power bombers, ghters and tanks powered postwar bulldozers, tractors and harvesters. Dichloro-diphenyl-trichloroethane (DDT), made infamous by Rachel Carson in Silent Spring, was rst developed to delouse allied soldiers and then applied as an agricultural pesticide. Most spectacularly, atomic ssion developed for the war-ending superweapon, was harnessed to produce electricity. Through the 1950s no downsides to such technologies were widely noticed or publicized. After a decade's time lag, however, their detrimental effects began to be evident to the naked eye, nose and ear. Air over major cities became dirty and smelly and pulsed with the ubiquitous noisy throb of gasoline and diesel motors. Rivers became open sewers, murky with municipal and industrial waste. A whole North American Great Lake appeared to be dying. Soil erosion accelerated. Spilled oil fouled beaches. Mankind was poised to realize the long held dream of conquering nature, only to nd that "to the victor belong the spoils" was in the case of this triumph an ironic

proverb. The cartoon character Pogo's malapropism was often quoted: " we have met the enemy and he is us."

This great awakening to an environmental crisis occurred in the most hyper-energetic and hyper-critical decade of the century in which the rhetoric of revolution was so commonplace that it began to be exploited commercially. (Advertisers, for example, urged Americans to join the Dodge Revolution). To address the monumental environmental crisis, nothing short of a revolution in ethics seemed adequate. Historically in the West, ethics appeared to be not just incidentally but militantly anthropocentric. A major pastime of Western philosophers had been to ruminate on what it was about human beings that made us unique, superior to all other creatures and exclusively worthy of moral treatment. In the Judeo Christian tradition of thought, it was our being created in the image of God; in the Greco Roman, it was our innate rationality. By whatever device, Western philosophy had with virtually one voice insisted upon a great gulf separating human nature from that of the lower animals, to say nothing of plants and the abiotic aspects of the environment. A revolutionary environmental ethic would have to de ate human pretensions and rehabilitate a philosophically denigrated nature.

ANTHROPOCENTRISM

Scarcely before the call by Richard Sylvan (Routley, 1973) for a new, environmental ethic had been heard, there appeared a staunch defense of the resources of anthropocentrism and the Western tradition of ethics to address the environmental crisis. Passmore (1974) argued that anthropocentric Western ethics would adequately protect the environment but only if actually implemented, if practiced as well as preached. He saw, furthermore, a dire threat to the achievements of Western civilization – its traditions of rationalism and humanism – in the call to develop a wholly new non-anthropocentric ethic and supporting metaphysics or to borrow one from Asian traditions of thought, as some had suggested (White, 1967).

Strong Anthropocentrism

The anthropocentric strain of environmental ethics has remained vigorous and persistent. A kind of unapologetic, uncritical anthropocentrism – sometimes characterized as strong anthropocentrism – still dominates environmental economics and most of public environmental policy. The environment represents a pool of natural resources or environmental goods, and a sink for wastes or environmental harms. The best allocation of environmental goods and harms is measured in units of human utility, quantified in units of currency such as dollars or pounds sterling and determined by conventional economic calculations (Krutilla and Fisher, 1985). Ethics enters the equation only when goods extracted from the environment by one person or group of persons results in harm suffered by another person or group. For example, if logging steep slopes results in siltation of streams which prevents salmon from successfully reproducing, a strongly anthropocentric environmental ethic might censure the loggers or the timber barons for whom they work, only if commercial salmon fisherman are materially injured. And then the moral matter might be settled by a transfer of funds from the injuring to the injured parties. In their own right, the soil, the salmon and the stream have no moral standing whatever.

The contribution of specialists in environmental ethics to strongly anthropocentric environmental policy is minimal in comparison with that of environmental scientists and economists. Most of the expertise informing such debates is hydrological, geological, biological and economic, etc. The specific contribution of environmental ethicists, under such strongly anthropocentric circumstances is to apply – off the rack, as it were – familiar, well-established ethical theories to the novel environmental situation (Pojman, 1999). The strongly anthropocentric environmental ethicist will, for example, come to an issue prepared to apply the latest model of Kantian ethics, utilitarianism, virtue ethics or rational choice theory generated in the ivory tower by the most celebrated philosophical pooh-bahs of the moment.

Environmental Justice

Because economics is more sensitive to considerations of efficiency than of justice, some strong anthropocentrists argue that environmental economics needs to be augmented by considerations of environmental justice (Wenz, 1988). For example, in the United States a greater percentage of black people than their percentage in the total population live uncomfortably close to a toxic waste dump or incinerator. Although the use of DDT has long been banned in the United States, it is still manufactured there, and exported for use in less developed countries. These and similar unequal distributions of environmental goods and especially harms appear *prima facie* to be unjust. Strongly anthropocentric theories of environmental justice are designed to critique and mitigate instances of environmental injustice.

Sometimes included within the purview of environmental justice is consideration of the welfare or rights of future human generations (if any there be) to natural resources and environmental amenities (Partridge, 1981; Sikora and Barry, 1978). Morally enfranchising future generations requires less application than creative modification of standard Western moral philosophy because new and challenging philosophical conundrums arise. How, for example, can non-existent persons have rights? Contemporary utilitarians define happiness not in terms of pleasure and pain as did classical utilitarians but in terms of preference satisfaction. How, thus, can we know what sort of environment

future human generations may prefer? They may prefer Disney-like simulations to real nature and virtual to actual reality. Furthermore, shifts in environmental policy to take into account the welfare and rights of future human generations might alter the actual composition of future generations. Imposing, say, a stiff energy tax on the present generation as a means to ensure that future generations can have their fair share of fossil fuels might, as one consequence, induce more people of the present generation to stay home at night, turn off the lights and go to bed early. That in turn might change the timing or frequency of the sexual activity of the present generation thus changing which gametes unite to form the embryos of future people. If so, a policy that was designed to benefit the people who would exist in the future, before the policy was adopted, would not benefit them at all – indeed it would have cost them their lives – and would benefit other future people instead. I do not suggest that these problems are fatal to the moral enfranchisement of future generations; I only suggest that they pose a distinctly philosophical challenge to a strongly anthropocentric environmental ethic that includes future human generations. Where future generations are concerned, therefore, environmental policy makers may feel as great a need to consult philosophers as to consult economists.

Weak Anthropocentrism

Weak anthropocentrism typically also morally enfranchises future human generations (Norton, 1984). In addition, it considerably broadens the notion of what counts as a human interest in the environment. People value nature, weak anthropocentrists point out, not only as a pool of material resources (food, fiber, fuel, and so on) but as a pool of psycho-spiritual resources as well. People recreate in unspoiled nature; take aesthetic pleasure and spiritual solace in it; they even take comfort in just knowing that bits of unspoiled nature exist, although they may never directly experience them. Indeed, some weak anthropocentrists suggest that nature might be a moral resource for people (Partridge, 1984).

Resource economists work diligently at the contingent valuation – or shadow pricing – of these natural amenities, because they rarely have an actual market price. People are asked what they would be willing to pay for a clean river in which to canoe or for a view of a mountain range unobscured by smog (Cummings *et al.*, 1986). Also among popular economic methods of calculating the monetary value of such is the travel-cost method in which the money people spend (on gasoline, food, lodging, outdoor gear and so on) to visit unspoiled natural areas is calculated to value (in the economic sense) a national park or designated wilderness area (Peterson and Sorg, 1989).

Unfortunately, an old growth stand of cathedral redwoods, say, will usually be worth far more money as a timber resource than as a psycho-spiritual resource, despite the best efforts of environmental economists to maximize the shadow monetary value of the latter. Weak anthropocentrists, therefore, typically insist that some human values should not be expressed in monetary terms (Norton, 1988). As Kant (1785) once remarked, some things have a price, others a dignity. People are not entirely unanimous in their opinion about what things have a dignity, any more than about what things are worth spending money on. The appropriate place for things with a price to compete is the market; the appropriate place for things with an alleged dignity to compete is the political arena (Sagoff, 1988). People vote with their money in the marketplace – for Rovers, say, but not for Yugos. For those things for which a price is inappropriate, people vote with their choices at the ballot box, albeit usually indirectly. They vote for representatives at various levels of government who, among other things, stand for certain values – for a community free of pornography shops, or for environmental quality: clean air and water, protection of wilderness areas and endangered species, reduction of greenhouse gases, and so on. Further, values settled politically should, ideally, trump market values. For example, in most industrialized societies, the political process has strongly affirmed the value of human emancipation: human beings should not be sold for slaves at any price, no matter what the market will bear. Similarly, weak anthropocentrists insist that humanly valued aspects of nature – designated wilderness areas, national parks, endangered species – should not be for sale at any price (Sagoff, 1988).

In addition to environmental goods and harms, attention has increasingly been directed to free ecological services performed by unspoiled nature, such as soil building and stabilization, water retention and purification, nitrogen fixation, and crop pollination. These too have been valued monetarily by economists (Costanza *et al.*, 1997). The monetary valuation of ecological services has also been criticized from a weak anthropocentric point of view (Sagoff, 1997).

Mention of the Kantian dictum that some things have a price, others a dignity, reminds us that Kant grounded the dignity of persons in their intrinsic value. By parity of reasoning, if some aspects of nature also have dignity, must they have it because they also have intrinsic value? However, anthropocentrism, by definition, weak as well as strong, restricts intrinsic value to human beings and acknowledges only the instrumental value of nature. The difference between strong and weak anthropocentrism may be summed up then as follows. Strong anthropocentrists recognize only the commodity, amenity and service value of nature and express all such values in monetary terms. The economic reduction of all environmental values, also severely short-changes future generations because a Euro presently in hand is worth more than a future Euro, the discount rate roughly corresponding to the current interest rate.

Thus, if an environmental economist were to compare the present monetary value of undeveloped potential commercial real estate in a metropolitan area, on the one hand, to its green-belt amenity value expressed in Euros for people living 100 years hence (estimated by contingent valuation and travel cost), on the other, the future environmental amenity value would be discounted at say 6% per year. Weak anthropocentrists recognize the commodity and service values of nature, but are reluctant to lump the wide range of psycho spiritual resources into the amorphous category of amenities. Most important, weak anthropocentrists oppose the expression of the psycho-spiritual values of nature in monetary terms. Although anthropocentric, all environmental values, in other words, are not preferences. One may prefer chocolate ice cream to strawberry and fish and chips to steak and kidney pie but the way one values Lake Windemere is not of the same order. Therefore, the most basic difference between strong and weak anthropocentrism is that the former treats all values as preferences, which are expressible in monetary terms. The latter treats preferences as a subset of human values and recognizes in addition a suite of environmental values – aesthetic, moral, religious, demeaned by strong anthropocentrists as mere amenities that transcend preferences and that are not appropriately expressed in monetary terms.

NON-ANTHROPOCENTRISM

Non-anthropocentrists seek to provide intrinsic value for non-human natural entities and/or nature as a whole.

Animal liberation and animal rights are not the same as environmental ethics. Indeed, in practice, concern for animal welfare and environmental concerns are often opposed. People for the ethical treatment of animals (PETA), for example, are often in the front lines of resistance to plans to protect endangered species of native plants by exterminating the bloated populations of feral goats, pigs, burros or what have you threatening them. Nevertheless, one approach to non-anthropocentric environmental ethics is based on the theoretical foundations of animal liberation and animal rights.

Contemporary anthropocentric environmental ethicists, strong and weak, typically take anthropocentrism for granted and do not bother to defend the intrinsic (or non-instrumental) value of human beings. Classically, however, anthropocentrists defended the intrinsic value of human beings by positing an intrinsic value conferring property, alleged to be possessed by human beings alone. One such candidate property is the image of God alleged to characterize all and only human beings. Such a property, however, is philosophically maladroit because it is non-empirical. Not on argument, but on faith, one must accept that human beings are in fact created in the image of God, for that image cannot be found by autopsy or inference. For those outside the specific communities of faith in which the image of God is a tenet – the Judaic, Christian and Muslim communities – such a proposition is either meaningless or dubious. Moreover, defending anrthropocentrism by appeal to a non-empirical intrinsic value conferring property, such as the image of God, would dangerously open up a Pandora's box of other, more noxious non-empirical properties that might even more narrowly restrict the class of beings possessing intrinsic value. Racists, for example, might find in the same religious sources a non-empirical property that morally disenfranchises people of color who allegedly bear the mark of Cain. Sexists, similarly, might find in the same religious sources a non-empirical property that morally disenfranchises women, who were created from Adam's rib and who are, thereby, made subservient to men. Thus, modern anthropocentric philosophers have overwhelmingly preferred to follow Kant (1785) and claim that reason is the intrinsic value conferring property possessed by all and only human beings.

The theoretical fulcrum leveraging the intrinsic value of non-human animals is the argument from marginal cases (Regan, 1979). If reason is not to serve as a mere sanitized and secularized substitute for the image of God, it must be an empirically detectable property. A minimally rational being must be able to do certain things – pass certain tests that evidence the possession of this property, such as to perform simple arithmetic calculations, solve simple practical problems, or use language meaningfully. Most human beings can do all such things, but some cannot. These are the marginal cases from which the argument takes its name. They are usually identified as infants, the severely mentally impaired and the abjectly senile. Because they are not rational, they do not have intrinsic value; and because they do not have intrinsic value, they fall beyond the moral pale and may be treated as we treat non-human animals. And how is that? We use animals as subjects for harmful medical experiments and tests, raise them in miserable conditions and slaughter them for food, hunt them for sport, display them in zoos and so on. The tails side (pun intended) of the argument is that many animals that conventional Western ethical theory and practice morally disenfranchise are minimally rational, according to these objective measures. Non-human primates have been observed to make and use tools in order to solve simple problems, have learned to use American sign language (to say nothing of the complex, but so far undeciphered social vocalizations of whales, dolphins, and elephants), to scheme and plan, and so on.

Animal Liberation

But back to the heads side of the argument from marginal cases coin. If we are to morally enfranchise the marginal cases, we must identify a capacity that the marginal cases possess as the intrinsic value conferring property. Bentham

(1789), a contemporary of Kant, argued that the capacity to experience pleasure and pain, called *sentience*, ought to be that property. Also, sentience is arguably more relevant to the bene t that it confers than reason. For why are we concerned how others treat us except that we can suffer? But many kinds of animals are also sentient. They too, therefore, possess intrinsic value and should thus be morally enfranchised equally.

Animal Rights

As Bentham knew full well, however, it is perfectly possible to raise animals comfortably and slaughter them painlessly. If we also hide their fate from them, so that they do not dread it, we can have our moral cake (or meat), so to speak, and eat it too. For that reason, Regan (1983) has proffered an alternative intrinsic value-conferring property being the subject of a life, that is, being a self with a capacity to enjoy a rich subjectivity shared by us and those animals that people most care about (mammals) as the conceptual foundation of animal rights. To be a subject of a life, according to Regan, implies, among other things, having desires, preferences, beliefs, memory of the past, anticipation of the future, and a sense of personal identity through time. In Regan s opinion all mammals one year old or more are subjects of a life, so understood, and thus should also enjoy the basic rights of life, liberty, and the pursuit of happiness.

Subjects of a life represent only a tiny fraction of the natural environment. Many more animals are sentient than are subjects of a life. But even if we stipulate that sentience is the proper intrinsic value conferring property and that all animals are sentient including those without a central nervous system animals, nevertheless, still represent only a small part of the environment. Hence, even if all animals were granted full moral standing, only a small part of the environment would be morally enfranchised. Therefore, some environmental philosophers, concerned not exclusively or even primarily about animals, but about the environment more generally, have tried to build a more inclusive non-anthropocentric ethic on the theoretical platform of animal liberation and animal rights theory.

I shall turn to that construction project in a moment. Before leaving the present matter, I should note that some partisans of animal liberation/animal rights argue that animal-oriented ethics, *per se*, may double dip as environmental ethics. At rock bottom, the argument runs parallel to the argument that strong anthropocentrism may serve as an environmental ethic (Jamieson, 1998). Wild animals can survive and ourish only in appropriate habitat. To ensure the welfare or protect the rights of animals would, therefore it seems, require us to preserve their habitat. We could call this a strong zoocentric environmental ethic. Undeveloped, the environment is instrumentally valuable to a wide variety of animals, as well as to us human beings as a pool of natural resources. The fatal problem with strong zoocentrism, as it seems to me, emerges when we consider that different kinds of animals have different habitat requirements. Thus preserving the habitat of one kind of animal will evict another kind. And if, as Singer (1977) reasons, all animals are equal, we have no theoretical justi cation for being biased in favor of one kind of animal instead of another. How thus can we say that habitat for endemic, native salmon spawning is to be preserved at the cost of displacing habitat for cosmopolitan, exotic carp; or that woody habitat for white tailed deer is to be preserved at the cost of displacing grassy habitat for domestic cattle?

BIOCENTRISM

Just as animal liberation and rights theorists challenge reason as the intrinsic value conferring property, so biocentric environmental ethicists challenge sentience or being a subject of a life as the intrinsic value conferring properties. The capacity to experience pleasure and pain, to say nothing of the suite of capacities comprehended by the phrase *subject of a life*, did not come into existence gratuitously or for their own sakes. Rather, sentience and most other capacities of consciousness evolved to foster the preservation of the organisms that possess them (Goodpaster, 1978). What is of ultimate value to organisms is to live and ourish. Pain and pleasure are powerful motivators toward that end, rewarding life-fostering behaviors and punishing life-threatening ones. The ability to remember the past and imagine the future enables organisms to learn from experience and to anticipate eventualities, which enhance their ability to survive and ourish. But if life itself is the be all and end all of organic existence, then maybe we should think that all living beings have intrinsic value.

The rst biocentrist seems to have been Schweitzer (1923) who insisted upon a reverence for life. He was a professional physician and musician, but only an amateur philosopher. A close study of Schweitzer s rhetoric reveals that he was primarily in uenced by Schopenhauer (1818), a neo Kantian philosopher who argued that the unknowable *Ding an sich* (thing in itself), which Kant believed to lurk in all phenomena, was the will to live. The will to live is one and the same in all things, inanimate as well as animate, according to Schopenhauer. Schweitzer, however, seems not to have appreciated the full sweep and grandeur of Schopenhauer s philosophical vision and himself thought the will to live inhabited only living beings. Therefore, just as we human beings experience it vividly and poignantly when our lives are threatened, so too do all other kinds of living beings. A biocentric ethic, Schweitzer believed, could be based on the capacity that we cognitively advanced living beings have for empathy and compassion with all

the others, who are, in essence, identically the same as ourselves.

Such a frankly metaphysical grounding of intrinsic value in nature is now quite out of philosophical fashion, though Schweitzer remains popular. Independently of Schweitzer, Feinberg (1974) suggested that having interests is what entitles a being to basic moral rights and that interests are compounded of *conations*, which consist of drives, aims, goals, latent tendencies, directions of growth and natural fulfillments – whether conscious or not. Conative plants and other living beings, although lacking consciousness of any kind, may nevertheless have interests, in this sense, and thus intrinsic value, and moral rights. Feinberg's suggestion was first taken up by Goodpaster (1978), then developed by Taylor (1986) into a full fledged biocentric theory of environmental ethics. Although Taylor carefully distinguishes between inherent worth and intrinsic value, this and other such conceptual niceties are too fine grained for presentation here. The following must suffice. Parallel to Regan's notion of a subject of a life, Taylor argues that all organisms are teleological centers of life. The operative term, here, *teleological* has long been in the philosophical lexicon and is formed from the Greek *telos*, meaning end, goal, or purpose. All organisms have innate drives, aims, goals – *teloi* in a word – which can be realized or frustrated. The most basic ones are to grow, to flourish, and to reproduce. Therefore, all organisms have inherent worth (intrinsic value) and all have it equally. Taylor avoids going so far as to claim that all teleological centers of life have rights, but he does argue that they are owed respect. A moral agent should respect all organisms and leave them alone to realize their own ends.

How then can a moral agent realize his or her own *teloi*? One must eat, be clothed, sheltered, educated, cured, all at the expense of other teleological centers of life. Taylor (1986) attempts to resolve morally the inevitable conflicts of interest arising between equally valuable teleological centers of life. He begins with the right of each person to self-defense. Taylor argues that when, for example, a disease-causing bacterium invades one's body, one is entitled to defend oneself with lethal antibiotics. Then to this unambiguous paradigm of self defense he assimilates the more problematic cases – taking the life of another organism to feed oneself, to clothe and shelter oneself, and so on.

ECOCENTRISM

Taylor's arguments justifying human exploitation of other teleological centers of life seem inconsistent with the severe constraints of his biocentric theory of environmental ethics, and are therefore not very convincing. But even if they were, biocentrism is beside the point. Environmentalists are simply not concerned about the welfare of individual shrubs, bugs and grubs. The medicinal eradication of millions of disease-causing bacteria in the intestines of a human being is not an environmental concern – except if the improvident use of antibiotics breeds resistant strains of bacteria; and then the concern would be less distinctly environmental than one of public health. Nor are environmentalists morally concerned about killing trees in a forest for the purpose of improving the overall health of the forest, or about culling excess deer on an overpopulated range. Environmental concerns typically focus on levels of biological organization beyond individual plants and animals – populations, species, communities, ecosystems, biomes, the biosphere – and on non-organic aspects of the environment, such as rivers, lakes, bays, gulfs, seas, oceans, soils and the atmosphere. Environmentalists are morally concerned about the extirpation of populations of certain species, such as the Bengal tiger from the Indian sub continent, about the threatened global extinction of species, such as the blue whale, about the integrity of biotic communities, especially temperate prairies and tropical rainforests that are so rich in variety of species, about the health of ecosystems, such as the Oostvaardersplassen or Chesapeake Bay, about anthropogenic acid deposition, atmospheric pollution, global warming and such.

To develop a relevant environmental ethic, one that directly addresses actual environmental concerns, we must step outside what may be called the modern classical paradigm of ethics. Goodpaster (1979) identified the common argument form of the two dominant schools of thought in modern ethics – one going back to Bentham (1789), the other to Kant (1785) – as a generalization of egoism. I (*ego*) demand that you consider my welfare or respect my interests when your actions affect me. I justify that demand by appeal to some capacity I possess – rationality, sentience, having a rich inner life or consciousness, having interests – which makes me intrinsically valuable and therefore entitles me to moral considerability. By the same token, however, I am obliged to consider the welfare or respect the rights of all those who possess the same capacity. This argument form underlies anthropocentrism, animal liberation/animal rights, and biocentrism. They differ only in the choice of the intrinsic value-conferring capacity and thus in the set of morally considerable entities they recognize. In the case of anthropocentrism, the intrinsic value-conferring property is reason; in that of animal liberation, it is capacity to suffer; in animal rights, experiencing a rich subjective life; in biocentrism, having interests. At the end of the day, however, the modern classical paradigm leaves us with only individuals – individual human beings, individual animals, individual organisms being morally considerable. Environmental concerns, however, are almost always holistic. Thus, we must go back to the theoretical drawing board and start afresh.

THE LAND ETHIC

Of all the environmental ethics so far devised, the land ethic, first sketched by Leopold (1949), is most popular among environmentalists. In his essay, *The Land Ethic*, Leopold begins by alluding to Darwin's account of the origin and development of ethics in the *Descent of Man*. The Leopold land ethic is thus grounded in evolutionary biology therefore making it more consonant than any alternative so far devised with the sciences that inform contemporary environmental concern (Callicott, 1989).

The existence of ethics presents a problem for Darwin's attempt to show how all things human can be understood as having gradually evolved by natural (and sexual) selection, from traits possessed by closely related species, his project in *The Descent of Man*. An ethic demands that moral agents selflessly consider the interests of others in addition to their own. The theory of evolution would seem to predict, however, that the selfish would out-compete the selfless in the struggle for existence, and thus survive and reproduce in greater numbers. Therefore, greater and greater selfishness, not selflessness, would seem to be selected for in any population of organisms, including those ancestral to *Homo sapiens*. But history indicates the opposite: that our remote human ancestors were more callous, brutal, and ruthless than we are. At least so it seemed to a refined English gentleman who while serving as naturalist on the round the world voyage of the HMS Beagle had observed first hand what he and his contemporaries regarded as states of savagery and barbarism similar to those from which European and Asian civilizations were believed to have emerged. Without a convincing evolutionary explanation of its existence and progressive development, Darwin's pious opponents might point to ethics among human beings as a clear signature by the hand of providence on the human soul.

To the conundrum presented by the existence and allegedly progressive development of ethics, Darwin's resolution is straightforward and elegant. For many kinds of animals and especially for *Homo sapiens*, life's struggle is more efficiently prosecuted collectively and cooperatively than singly and competitively. Poorly armed by nature, as solitaries, hominids would fall easy prey to their natural enemies or starve for lack of the wherewithal to obtain food. Together our primate ancestors might stand some chance of fending off predators and attacking prey larger than themselves. Like many other similarly situated species, evolving human beings thus formed primitive societies; or put more precisely, those hominids that formed primitive societies evolved. But without some rudimentary ethics, human societies cannot stay integrated. As Darwin (1871) puts it,

> No tribe could hold together if murder, robbery, treachery, & c., were common; consequently such crimes within the limits of the same tribe are branded with everlasting infamy'; but excite no such sentiment beyond these limits.

Darwin's speculative reconstruction of the evolutionary pathway to ethics begins with altruistic parental and filial affections which motivate parents (perhaps only the female parent in many species) to care for their offspring and their offspring to desire the company of their parents. Such affectionally bonded nuclear families are small and often ephemeral societies, lasting, as in the case of bears, only until the next reproductive cycle. But the survival advantage to the young of being reared in such social units is obvious. Should the parental and filial affections chance to spill beyond the parental-filial relationship to that between siblings, cousins and other close kin, such plurally bonded animals might stick together in more stable and permanent groups and defend themselves and forage communally and cooperatively. In which case there might also accrue additional advantages to the members of such groups in the struggle for life. Thus do mammalian societies originate in Darwin's account.

By themselves, the social impulses and sentiments are not ethics. An ethic is a set of behavioral rules, or a set of principles or precepts for governing behavior. The moral sentiments are, rather, the foundations of ethics, as Hume (1751) and Smith (1759) argued, a century or so before Darwin considered the matter. In addition to the social sentiments and instincts, *Homo sapiens* evolved to a high degree of intelligence and imagination and uniquely possessed a symbolic language. Hence, we human beings are capable of generally representing those kinds of behavior which are destructive of society (murder, robbery, treachery, & c.) and articulating prohibitions of them in emotionally colored formulae – thou shalt not kill, steal, bear false witness, etc. – which formerly we called commandments and today call moral rules.

So much then for the origin of ethics. Darwin goes on to account for the development of ethics. As human social groups competed with one another for resources, the larger and better organized out-competed the smaller and less well organized. Hence clans, firstly, merged into tribes; tribes, next, into nations; and nations, eventually, into republics. The emergence of each of these levels of social organization was attended by a corresponding expansion of ethics. Darwin (1871) sums up this parallel growth of ethics and society as follows: As man advances in civilization, and small tribes are united into larger communities, the simplest reason would tell each individual that he ought to extend his social instincts and sympathies to all the members of the same nation, though personally unknown to him. This point being once reached there is only an artificial barrier to prevent his sympathies extending to the men of all nations and races. Further, with the emergence of each new level in the social hierarchy – the clan, the tribe, the nation, the republic, the global village – the content of the moral code changed or was supplemented to reflect and facilitate the novel structure of each newly emerged level.

During Darwin's lifetime, a universal ethic of human rights was only dimly visible on the horizon. By the mid-twentieth century, when Leopold was gestating the land ethic, a universal human rights ethic may have seemed more nearly attainable. In any case, Leopold, often called a prophet, looked farther ahead than did Darwin himself, indeed farther ahead than Darwin could have looked in the absence of a well developed ecological world view. Leopold (1949) summarizes Darwin's natural history of ethics with characteristic compression: All ethics so far evolved rest upon a single premise: that the individual is a member of a community of interdependent parts. Then he adds an ecological element, the community model of the biota espoused most notably by Elton (1927). Ecology simply enlarges the boundaries of the community to include soils, waters, plants and animals, or collectively: the land (Leopold, 1949). When we all learn to see land as a community to which we belong not as a commodity belonging to us (Leopold, 1949) that same simplest reason, of which Darwin speaks, might kick in. And when it does, what results will be a land ethic that changes the role of *Homo sapiens* from conqueror of the land community to plain member and citizen of it (Leopold, 1949).

Basically, what Leopold did to cook up the land ethic was to take over Darwin's recipe for the origin and development of ethics, and add an ecological ingredient, the Eltonian community concept. According to Leopold (1949), a land ethic implies respect for fellow members and also for the community as such. The land ethic, in other words, has a holistic dimension to it that is completely foreign to the mainstream modern moral theories going back to Bentham and Kant. The holistic dimension of the land ethic – respect for the community as such, in addition to respect for its members severally – is, however, not in the least foreign to the Darwinian and Humean theories of ethics upon which it is built. Darwin (1871) could hardly be more specific or emphatic on this point. Actions are regarded by savages and were probably so regarded by primeval man, as good or bad, solely as they obviously affect the welfare of the tribe, – not that of the species, nor that of an individual member of the tribe. This conclusion agrees well with the belief that the so called moral sense is aboriginally derived from the social instincts, for both relate at first exclusively to the community. Hume (1751) insists that we must renounce the theory which accounts for every moral sentiment by the principle of self love. We must adopt a more public affection and allow that the interests of society are not, even on their own account, entirely indifferent to us.

That is not to say that Hume, certainly, and even Darwin make no theoretical provision for a lively concern for the individual members of society as well as for society *per se*. Darwin (1871) writes of the all important emotion of sympathy. Sympathy means *with feeling* and so can extend only to feeling – that is, sentient – individuals. It cannot extend to levels of social organization beyond the individual, which have no feelings *per se*. Hume and Darwin, however, recognized other moral sentiments than sympathy, some of which – patriotism, for example – relate as exclusively and specifically to societies as sympathy does to sentient individuals. In the Leopold land ethic, in any event, the holistic aspect eventually eclipses the individualistic aspect. Toward the beginning of *The Land Ethic*, Leopold (1949), as noted, declares that a land ethic implies respect for fellow members of the biotic community, as well as for the community as such. Toward the middle of *The Land Ethic*, Leopold (1949) speaks of a biotic right to continue but such a right accrues, as the context indicates, to species, not to individual specimens. Toward the end of the essay, Leopold (1949) writes a summary moral maxim, a golden rule, for the land ethic: A thing is right when it tends to preserve the integrity, stability and beauty of the biotic community. It is wrong when it tends otherwise. In it, there is no reference at all to fellow members. They have gradually dropped out of account as the *The Land Ethic* proceeds to its climax. Because of its focus on the biotic community as such, the Leopold land ethic may be called ecocentric.

Ultimately traceable, as it is, to the theory of moral sentiments developed in the eighteenth century by David Hume and Adam Smith, the several objects of moral respect recognized in the ecocentric land ethic, do not so much have intrinsic value as they are valued intrinsically. The difference is not merely semantic. Intrinsic value, as conceived by Kant and his contemporary intellectual descendants, is what philosophers now call a *supervenient property* – that is, an objective property that piggybacks on another objective property. For Kant, as noted, that latter property is reason, for Singer it is sentience, for Regan it is being the subject of a life, and for Taylor, being a teleological center of a life. For the contemporary intellectual descendants of Hume and Smith, however, value is first and foremost a verb, not a noun that designates an objective (albeit supervenient) property. Something is, in other words, valuable only if it is valued by some valuing subject. And we human valuing subjects value things in at least two different ways: instrumentally and intrinsically. One values one's house, automobile and other useful artifacts instrumentally. One values one's self, spouse, children, other relatives, friends, neighbors, fellow citizens, fellow man intrinsically. One also values intrinsically one's family, municipality, country and the human race, *per se* – that is, as collective wholes. One may value intrinsically a wide array of other things as well. Indeed, one can value anything under the sun intrinsically – the Eiffel Tower, for example, or even a worn-out old shoe. But we usually do not value any and everything intrinsically; we usually do so for a reason. A

fundamental reason is a sense of belonging to a community of interdependent parts.

The Problem of Ecofascism and the Land Ethic

Holism is the land ethic's principal strength, because actual environmental concerns are holistic, but also its principal liability. According to Leopold (1949), we *Homo sapiens* are but plain members and citizens of the biotic community. Then it would seem that the summary moral maxim of the ecocentric land ethic applies to *Homo sapiens* no less than to the other members and citizens of the biotic community. A human population of more than six billion individuals is a dire threat to the integrity, stability, and beauty of the biotic community. Thus the existence of such a large human population is ethically wrong. To right that wrong should we not do what we do when a population of white tailed deer or some other species irrupts into and threatens the integrity, stability, and beauty of the biotic community? We immediately and summarily reduce it, by whatever means necessary, usually by randomly and indiscriminately culling the members of such a population – respectfully, of course – until its numbers are optimized.

It did not take its critics long to draw out the apparently vitiating implication of the ecocentric land ethic. According to them, the land ethic is a case of environmental fascism because the good of ecological wholes takes precedence over the good of the component individuals, including human individuals, according to Aiken (1984), Regan (1983), Ferre (1996), and Shrader-Frechette (1996). If so, it must be rejected as monstrous. Happily, it does not. To think that it does, one must assume that Leopold proffered the land ethic as a substitute for, not an addition to, our venerable and familiar human ethics. But he did not. Leopold refers to the various stages of ethical development – from tribal mores to universal human rights and finally, to the land ethic – as accretions. Accretion means an increase by external addition or accumulation. The ecocentric land ethic is an addition to our several accumulated social ethics – now more than ever, strongly individualistic – not something that is supposed to replace them. With the advent of each new stage in the accreting development of ethics, the older stages are not erased or replaced. I, for example, am a citizen of a republic, but I also remain a member of an extended family, and a resident of a municipality. And it is quite evident to us all, from our own moral experience, that the duties attendant on citizenship in a republic (to pay taxes, to serve in the armed forces or in the Peace Corps, for example) do not cancel or replace the duties attendant on membership in a family (to honor parents, to love and educate children, for example) or residence in a municipality (to support public schools, to attend town meetings). Similarly, the duties attendant upon citizenship in the biotic community (to preserve its integrity, stability, and beauty) do not cancel or replace the duties attendant on membership in the human global village (to respect human rights).

As members of multiple communities, each generating ethical obligations, how do we prioritize when duties to one community or its members conflict with duties to another? Naess (1989) suggested two complementary priority principles for resolving such conflicts. The first we might call the inverse scale principle (ISP). One should give priority to obligations to one's nearest and dearest community members and one's nearest and dearest community as such – to one's family, municipality, etc., in that order. Hence, if in a time of general scarcity, one faced a choice between sharing one's severely limited resources with family members or with unrelated neighbors, the right thing to do would be to share with family members and refuse neighbors. The second we might call the degree-of-interest principle (DIP), which counters the ISP. If the interests at stake are of unequal strength, the lesser interest should give way to the greater. For example, in circumstances not of general scarcity but of unequal distribution of plentiful resources, some are needier than others. If one is relatively wealthy and one's neighbor is desperately poor, then the strong interest in having the wherewithal for survival of one's neighbor should take priority over the weaker interest of satisfying the superfluous consumer preferences of oneself and one's family members.

Applying these priority principles to moral conflicts arising between obligations relative to a biotic community and those relative to a municipality, we might conclude that if our choice were between the destruction of a regional biotic community (and the extinction of its endemic species), on the one hand, and the starvation of the citizens of local human communities, on the other, then priority should be given to our obligations relative to the municipality, in accordance with the ISP. However, in the famous case of the conflict between the endangered spotted owl and the threatened old growth forest in the Pacific Northwest of the United States, on the one hand, and the region's logging/milling communities, on the other, that is not the conundrum we face. Other employment alternatives are available to loggers and mill workers. The biotic community interests at stake are much greater – the destruction of a unique biome and the extinction of its endemic species. Hence in this case, the DIP countermands the ISP. Unfortunately, in some parts of the world, the ethical dilemma does involve the very livelihood, not just the lifestyles of local peoples. For example, some people face the choice of feeding themselves and their families and by doing so contributing to the destruction of tropical forests and a global mass extinction event, on the one hand, or starving, on the other. For them the choice is clear and unambiguous. They must slash and burn. Because they are not my neighbors or fellow nationals, however, it is not entirely

clear what national and international policies, with respect to such practices, I should support.

Change and the Land Ethic

Leopold penned the land ethic at mid century. Ecology then represented nature as tending toward a static equilibrium, and portrayed disturbance and perturbation, especially those caused by *Homo sapiens*, to be abnormal and destructive. In view of the shift in contemporary ecology to a more dynamic paradigm (Botkin, 1990), and in recognition of the incorporation of natural disturbance to patch and landscape scale ecological dynamics (Pickett and Ostfeld, 1995), we might wonder whether the land ethic has become obsolete. Has the paradigm shift from the balance of nature to the ux of nature in ecology invalidated the land ethic? I think not, but recent developments in ecology may require revising the land ethic. From Leopold s original summary moral maxim or golden rule of the land ethic, we may be left now with only the preservation of a biotic community s beauty as a criterion of a thing s land-ethical rightness or wrongness.

Despite all the idle talk about beauty being in the eye of the beholder, ecological beauty might not be an altogether inadequate or relativistic criterion by means of which to judge a thing s environmental rightness or wrongness. Hume (1751) notes that broad shoulders, a lank belly, rm joints, a taper leg; all these are beautiful in our species, because signs of force and vigor. Natural beauty is far less relative and ckle a judgment of taste than we are wont latterly to acknowledge; it is, as it were, an aesthetic registry of robust good health. And indeed Leopold (1999) linked ecological beauty to land health. Land was healthy and therefore beautiful to those with a re ned taste in natural objects in Leopold s estimation, when its ecological processes were being carried out normally. Such ecological processes include photosynthesis; energy transfer through lengthy food chains and tangled food webs, capped by long lived, large bodied carnivores; the recruitment, retention, and recycling of nutrients; the stabilization of soils; the modulation of water ows; and the resistance to and rapid recovery from perturbation by wind, re, ood, pest, pathogen, and other disturbances.

Leopold was, moreover, aware of and sensitive to natural change. He knew that conservation must aim at a moving target. How can we conserve a biota that is dynamic, ever changing, when the very words *conserve* and *preserve* especially when linked to *integrity* and *stability* connote arresting change? The key to solving that conundrum is the concept of scale. Scale is a general ecological concept that includes rate as well as scope; that is, the concept of scale is both temporal and spatial. And a review of Leopold s *The Land Ethic* reveals that he had the key, though he may not have been aware of just how multiscalar is change in nature. There, Leopold (1949) writes, Evolutionary changes ••• are usually slow and local. Man s invention of tools has enabled him to make changes of unprecedented violence, rapidity, and scope. Leopold was keenly aware that nature is dynamic, but, under the sway of mid-century equilibrium ecology, he conceived of natural change primarily in evolutionary, not in ecological terms. Nevertheless, scale is equally normative when ecological change is added to evolutionary change, that is, when normal climatic oscillations and patch dynamics are added to normal rates of extinction, hybridization, and speciation.

As noted, *Homo sapiens* is, in Leopold s opinion, a part of nature, a plain member and citizen of the land community. Hence, anthropogenic changes imposed on nature are no less natural than any other. Nevertheless, because *Homo sapiens* is a moral species, capable of ethical deliberation and conscientious choice, and evolutionary kinship and biotic community membership add a land ethic to our familiar social ethics, anthropogenic changes may be land-ethically evaluated. But by what norm? The norm of appropriate scale.

Let me rst recount Leopold s use of the temporal scale of evolutionary change as a norm for evaluating anthropogenic change. Consider the current episode of abrupt, anthropogenic, mass species extinction which many environmentalists intuitively regard as the most morally reprehensible environmental thing going on today. Episodes of mass extinction have occurred in the past, though none of those has been attributed to a biological agent. Such events are, however, abnormal. Normally, speciation outpaces extinction which is the reason why biological diversity has increased over time. So, what is land-ethically wrong with current anthropogenic species extinction? Species extinction is not unnatural. On the contrary, species extinction anthropogenic or otherwise is perfectly natural. But the current rate of extinction is wildly abnormal. Does being the rst biological agent of a geologically signi cant mass extinction event in the 3.5 billion years tenure of life on Planet Earth morally atter us *Homo sapiens*? Doesn t that make a mockery of the self-congratulatory species epithet: the sapient, the wise species of the genus *Homo*?

Now let s apply this model to a quandry that Leopold himself never considered. Earth s climate has warmed up and cooled off in the past. So, what s land-ethically wrong with the present episode of anthropogenic global warming? We are a part of nature, so our recent habit of recycling sequestered carbon may be biologically unique, but it is not unnatural. A land-ethical evaluation of the current episode of anthropogenic climate change can, however, be made on the basis of temporal scale and magnitude. We may be causing a big increase of temperature at an unprecedented rate. That s what s land-ethically wrong with anthropogenic global warming.

Temporal and spatial scale in combination are key to the evaluation of direct human ecological impact. Long before *Homo sapiens* evolved, violent disturbances regularly occurred in nature. And they still occur, quite independently of human agency. Volcanoes bury the biota of whole mountains with lava and ash. Tornadoes rip through the countryside, leveling houses and trees. Hurricanes erode beaches. Lightning sets fires that sweep through forests and savannas. Rivers drown floodplains. Droughts dry up lakes and streams. Why, therefore, are analogous anthropogenic disturbances – clear cuts, beach developments, hydroelectric impoundments, and the like – environmentally unethical? As such, they are not. Once again, it's a question of scale. In general, frequent, intense disturbances, such as tornadoes, occur at small, widely distributed spatial scales, while spatially more extensive disturbances, such as droughts, occur less frequently. And most disturbances at whatever level of intensity and scale are, mathematically speaking, stochastic (random) and chaotic (unpredictable). The problem with anthropogenic disturbances – such as industrial forestry and agriculture, suburban development, drift net fishing – is that they are far more frequent, widespread, and regularly occurring than are non-anthropogenic disturbances. They are well out of the spatial and temporal range of disturbances experienced by ecosystems over evolutionary time.

Proponents of the new flux of nature paradigm in ecology agree that appropriate scale is the operative norm for ethically appraising anthropogenic ecological perturbations. For example, Pickett and Ostfeld (1995) note that the flux of nature is a dangerous metaphor. The metaphor and the underlying ecological paradigm may suggest to the thoughtless and greedy that since flux is a fundamental part of the natural world, any human caused flux is justifiable. Such an inference is wrong because the flux in the natural world has severe limits ••• two characteristics of human-induced flux would suggest that it would be excessive: fast rate and large spatial extent.

Among the abnormally frequent and widespread anthropogenic perturbations that Leopold (1949) himself censures in *The Land Ethic* are the continent-wide elimination of large predators from biotic communities in Europe and North America; the ubiquitous substitution of domestic species for wild ones; the ecological homogenization of the planet resulting from the anthropogenic worldwide pooling of faunas and floras; the ubiquitous polluting of waters or obstructing them with dams.

The summary moral maxim of the land ethic, however, must be rendered more dynamic in light of developments in ecology over the past quarter century. Leopold acknowledges the existence and land-ethical significance of natural environmental change, but seems to have thought of it primarily on a very slow evolutionary temporal scale. Even so, he thereby incorporates the concept of inherent environmental change and the crucial norm of scale into the land ethic. In light of more recent developments in ecology, we can add norms of scale to the land ethic for both climatic and ecological dynamics in land-ethically evaluating anthropogenic changes in nature. One hesitates to edit Leopold's elegant prose, but as a stab at formulating a dynamized summary moral maxim for the land ethic, I will hazard the following: A thing is right when it tends to disturb the biotic community only at normal spatial and temporal scales, so as not to mar its beauty (or health). It is wrong when it tends otherwise.

SUMMARY

In conclusion, then, there are two fundamental genera of environmental ethics, anthropocentrism and non-anthropocentrism. Of the former there are two species, strong and weak. Strong anthropocentrism reduces all environmental values to preferences capable of economic expression and valuation in monetary terms. All environmental decisions can be made by weighing benefits against costs, tempered by considerations of environmental justice. Weak anthropocentrism agrees that all environmental values are instrumental, but insists that some are not preferences. Human environmental values that conflict with preferences are more properly institutionalized politically than made to compete economically.

There are several species of non-anthropocentrism. Two, *animal liberation* and *animal rights*, are not, properly, environmental ethics; and indeed, are often at odds with environmental concerns and values. A third, *biocentrism* – the proposition that all living beings possess intrinsic value and merit respect – builds upon the theory of animal rights. Though proffered as an environmental ethic, biocentrism is hardly relevant because it morally enfranchises only individuals, while actual environmental concerns are almost always holistic.

Ecocentrism, a fourth species of non-anthropocentrism, is holistic in focus. In its original articulation by Aldo Leopold, the integrity, stability, and beauty of the biotic community is the standard of right environmental conduct. Allegations to the contrary notwithstanding, ecocentrism does not entail environmental fascism. For, as Leopold conceives it, a *land ethic* is an addition to, not a substitute for, our more individualistically inclined social ethics and all other things being equal, our more venerable social ethics take precedence over the land ethic when they conflict. Contemporary ecology, however, posits a more dynamic than stable nature and more loosely associated than tightly integrated biotic communities, existing at multiple scales, subject to a wide variety of periodic disturbances. A more dynamic ecocentrism would morally limit anthropogenic change and disturbance to normal temporal and spatial scales, thus to preserve the land's health and beauty.

Environmental Movement – the Rise of Non-government Organizations (NGOs)

Elizabeth May
Sierra Club of Canada, Ottawa, Canada

Although active in promoting environmental policies since the 19th century, environmental NGOs became a more profound force in the latter decades of the 20th century.

Environmental groups operate at local, community, provincial/state, national and international levels. Generally, they exist based on public nancial support and involve millions of citizens around the world. Typically and culturally, NGOs are more robust in democratic societies, but emerge as countries transit from totalitarian to democratic governance.

The rise of NGOs has corresponded to a declining role of the nation state in an era of increased global corporate rule. In response, environmental NGOs are themselves increasingly globalized and acting in signi cant ways on international issues, from United Nations (UN) fora to the World Trade Organization (WTO).

The role of NGOs has been accepted by the UN organizations with increasing openness through the preparatory process for the United Nations Conference on Environment and Development (UNCED), and the June, 1992 Rio Earth Summit. Resistance to NGO participation in other institutions, such as the World Bank and the WTO, has spilled over into the streets of Washington, DC for a number of years and in Seattle in November 1999 at the third ministerial meeting of the WTO.

NGOs, as a signi cant force within civil society, will likely continue to occupy an increasing area of political space as the challenges of global environmental change weaken existing institutions.

Reformers of all kinds have long organized themselves into groups and associations to press for change. Successful movements put themselves out of business, such as the slavery abolitionists and the women's suffrage movement. The first successful mass mobilization campaign can be traced back to the UK abolitionists' campaign in the 18th century. NGOs became an accepted part of society dating from the Franco–Prussian war and the creation of the Red Cross.

Although the term *environment* did not come into common usage until the 1960s, concern for nature, clean air and water and protection of animals led to the establishment of the earliest environmental groups toward the end of the 19th century.

A case can be made for the inclusion of public health activists as early environmentalists. Florence Nightingale, for example, bemoaned that the Thames was used as an open sewer and worked to improve standards of public health through improved sanitation:

> It did strike me as odd sometimes, that we should pray to be delivered from plague, pestilence, and famine,' when all the common sewers ran into the Thames and fevers haunted undrained land, and the districts which cholera would visit could be pointed out. I thought that before cholera came that we might remove these causes, not pray God would remove the cholera.
>
> *Suggestions for Thought* (1860)

The killing fogs of London's smoke choked air also led to public protest and movements for change focused on the deleterious effects on public health. Such concerns had been voiced for hundreds of years, but most notably grabbed attention in 1952 when 4000 people died in an acute air pollution event in London. Similarly, the development of British common law remedies for nuisance and riparian rights were intimately tied to protection of one's right to clean air and clean water. Still, the existence of organized environmental groups is seen as a more recent phenomena.

THE NATURE LOVERS

In North America, early environmental groups were organized as hiking clubs, such as the Williamstown Club (1863), the White Mountain Club (1873) and the Appalachian Mountain Club (1876). In 1875, people concerned with the state of the nation's forests organized the American Forestry Association. Unlike its current incarnation, it initially championed forest protection, urged tree planting, lobbied for parks and successfully established Arbor Day.

As the industrial revolution and expanding populations in the Eastern United States pressed against shrinking wilderness, these societies expressed the romantic longing for wildness, influenced by Henry David Thoreau and his 1854 book *Walden* (*see* Thoreau, Henry David, Volume 5).

In this period, both the Audubon Society and the Sierra Club were formed. The Audubon Society and the American Ornithological Society were formed in the 1880s, with a primary mission of the study and protection of wild birds. The Sierra Club (*see* Sierra Club, Volume 5) was founded in 1892 with the broader goal of protecting large tracts of wilderness in the western US. Although the word *environment* was not used at the time, protection of wildness and the urgent imperative to protect nature from ruthless exploitation were common themes in the group's early literature. Founder John Muir (*see* Muir, John, Volume 5) wrote of government attitudes to American forests:

> (the government) is like a rich and foolish spendthrift who has inherited a magnificent estate in perfect order, and then has left his fields and meadows, forests and parks, to be sold and plundered and wasted at will, depending on their inexhaustible abundance.
>
> (Turner, 1985)

The Sierra Club was founded with the goal of introducing urban dwellers to the magnificence of the Sierra Nevada. Muir believed that by experiencing and enjoying the natural world, people would, through transformative and transcendental experience, become converts to the cause of preserving it. This formula proved very successful. Prior to the establishment of the Sierra Club, Muir himself helped persuade outdoorsman, adventurer and hunter US President Teddy Roosevelt to protect critical wilderness (*see* Roosevelt, Theodore, Volume 5). The first national park had been Yellowstone in 1872, but public reactions had been adverse.

In a strategy that foreshadowed Sierra Club's tactics for the next century, Muir plotted a campaign to make Yosemite a national park. The plan included an insider Washington strategy with a Yosemite bill the locus of lobbying, a media strategy with articles in popular magazines extolling the virtues of Yosemite and the urgency of protecting it from development, penned by the now famous Muir, and mobilizing individuals by taking concerned people into the Yosemite wilderness. The Washington and New York lobbying was primarily the work of Muir's friend and collaborator Robert Underwood Johnson, whose role as associate editor of the nation's leading literary monthly, *The Century*, proved crucial in mobilizing public support. The Yosemite bill passed into law in 1890.

But the wilderness of Yosemite was incompletely protected with key areas, particularly the Hetch Hetchy Valley, remaining in state, rather than federal, control. Moreover, the magnificent sequoia forests north of the park were unprotected. These and other wilderness campaigns became the focus for the Sierra Club.

In the spring of 1903 Muir accomplished the ultimate in lobbying coups; a camping trip into Yosemite with President Teddy Roosevelt. By the end of the trip, Teddy Roosevelt declared it would be a shame to our civilization to let them (sequoias) disappear. They are monuments unto themselves , (Turner, 1985, 826). It took several years more effort to get the bill expanding protection of Yosemite to include the Hetch Hetchy Valley through the California legislature, but ultimately, Muir and the Sierra Club prevailed. But the victory was not to be permanent.

THE CONSERVATION MOVEMENT

Across North America another species of environmentalism was on the rise. If Muir and Sierra Club could be described as *preservationist*, the movement for scientific forestry and wise use of natural resources was christened *conservationist*. The leading practitioners and advocates for conservation were Gifford Pinchot and Bernard Fernow. Pinchot was the son of a wealthy Connecticut family, who studied forestry in Germany and became the first dean of the Yale School of Forestry, created through a large Pinchot family donation. German born and trained, Fernow was already established as a forester when Pinchot came on the scene. Pinchot replaced Fernow as the director of the Division of Forestry within the Department of Agriculture and Fernow became the first dean of forestry at the University of Toronto.

Both believed in the efficient use of forests and favored human use and benefits over the love of and protection of wilderness in its own right. Pinchot and Fernow established forestry principles that persist to this day, favoring even-aged forest stands and the elimination of old growth. They championed sustained yield forest management.

Initially, Muir and Pinchot were in league. In 1895, Muir even wrote:

> The forests must be, and will be, not only preserved, but used; and ••• like perennial fountains ••• be made to yield a sure harvest of timber, while at the same time all their far reaching (aesthetic and spiritual) uses may be maintained unimpaired.

But the unity of preservationists and conservationists was not to last. Two bitter disputes permanently split the American conservation movement. The first was the question of the purpose and level of protection for National Forests. Pinchot and his followers believed that scientific forestry and logging should take place in these forests, while Muir and the Sierra Club had succeeded in having 21 million acres (eight million hectares) of forest set aside in 1897 as forest reserves with no mention of a commercial purpose.

Although Muir originally tried to keep both forces unified in order to ensure the success of the cause of forest reserves, the tension between preservation and wise use ultimately snapped coalition efforts. Pinchot's forces succeeded in having Congress pass a Forest Management Act (1897) which stated that the central purpose of reserves was to furnish a continuous supply of timber for the use and necessities of citizens of the United States . The Act also included mining and grazing as acceptable activities within the forest reserve system.

Pinchot's colleague Bernard Fernow summed up the conservationist view, the main service, the principal object of the forest has nothing to do with beauty or pleasure. It is not except incidentally an object of aesthetics, but an object of economics .

The conversion of national forest reserves to logging concessions was a blow to Muir, but it was nothing compared to the heart-breaking loss in the fight for the Hetch Hetchy.

Muir and the Sierra Club had succeeded in having the dramatic Hetch Hetchy Valley added to the Yosemite National Park. One hundred and fifty miles from the growing urban center of San Francisco, the Yosemite wilderness was seen through two very different lenses. To Muir, in wildness lay spiritual salvation:

> thousands of tired, nerve shaken, over civilized people are beginning to nd out that going to the mountains is going home; that wildness is a necessity; and that mountain parks and reservations are useful not only as fountains of timber and irrigating rivers, but as fountains of life.
>
> (Nash, 1967)

For others, the Hetch Hetchy Valley held another form of salvation, an abundant source of water for a parched city. The proposed damming of the Hetch Hetchy was sacrilege to Muir, but sensible to the wise-use conservation movement. As Pinchot wrote:

> As to my attitude regarding the proposed use of the Hetch Hetchy by the city of San Francisco ••• I am fully persuaded that ••• the injury ••• by substituting a lake for the present swampy oor of the valley ••• is altogether unimportant compared with the bene ts to be derived from its use as a reservoir.

San Francisco s engineers had proposed damming the Hetch Hetchy in 1882, long before its inclusion in the Yosemite National Park. In 1890, even after its status as a protected area within a national park was established, the Mayor of the day requested permission to dam the river and use the water. The Secretary of the Interior, Ethan A Hitchcock refused, noting that a dam was inconsistent with the national park designation.

But in 1906, San Francisco suffered the double blow of a devastating earthquake and re. The city s need for water aroused public sympathy far more than the preservationists love of wilderness. In 1908, Hitchcock s successor, James R Gar eld, approved the plan. The aftermath was an historic point in the growth of environmental groups as Muir, Johnson and the Sierra Club launched the rst nationwide environmental protest campaign in US history. The Hetch Hetchy became a national issue.

The ght was bitter and the rhetoric brutal. Muir, who had long written of wilderness in terms of religious reverence, now wrote of its despoilers as Satanic. Johnson also took up the cause of protection of beauty and nature against the materialistic followers of Mammon in the context of a larger morality play. While Muir and Johnson urged that other sources be found for the city s water needs, even sympathetic President Teddy Roosevelt was convinced that there was no other suitable source for water.

In 1912, Muir called those promoting the dam scheme:

> temple destroyers, devotees of ravaging commercialism ••• having a perfect contempt for nature ••• instead of lifting their eyes to the God of the Mountains, lift them to the Almighty Dollar. ••• Dam Hetch Hetchy! As well, dam for water tanks the people s cathedrals and churches, for no holier temple has ever been consecrated in the heart of man.

In what may have been most painful for Muir, dam supporters included friends and residents of San Francisco within the Sierra Club. Warren Olney, one of the Club s founders, led a Club faction in support of the dam. Muir and Johnson acted through the California Branch of the Society for the Preservation of National Parks, to avoid the internal con ict. In 1910, through a referendum within the Sierra Club, Muir established that the Club also favored preservation over damming the Hetch Hetchy, by a vote of 589 161. Still, having to ght within the organization he had founded was a bitter pill. The San Francisco media lampooned Muir as a cranky old fanatic who cared more for trees than people. And there was no doubt his rhetoric had become more fanatical. But nationally, Muir and the preservationists had widespread support, with articles in the *New York Times* and many popular magazines. The rift within the conservation movement was profound. In 1913, the head of the National Conservation Association, Harry Slatterly, wrote to the Secretary of the Interior, Unfortunately, our good friends the nature lovers are still unreasonable in their attitude. There is grave danger they will again be able to block this most necessary legislation (Hays, 1972).

Muir and the Sierra Club organized a broader coalition, pulling away groups, such as women s clubs, traditionally supportive of Gifford Pinchot and the utilitarian conservationists to the cause of Hetch Hetchy. The Hetch Hetchy issue galvanized a new wilderness preservation movement, with effective support from the women s clubs, hunter and sportsmen s groups, outing clubs, scienti c societies and academic institutions. One Senator noted that he had received 5000 letters urging him to save the Hetch Hetchy. National support was strong and Muir and his supporters felt the protests would succeed in thwarting the bill to dam the valley. In November 1913, Muir wrote to Johnson, we re bound to win, enemy badly frightened, Up and smite em!

But the quiet and effective lobbying of in uential San Franciscans had done wonders for the city that wanted water. On December 6, 1913 the Senate vote favored damming the Hetch Hetchy, and despite best efforts, no presidential veto followed.

Muir and the preservationists accepted their defeat on the Hetch Hetchy, nding solace, as Muir wrote, in the fact that the conscience of a whole country has been aroused from sleep . It was no exaggeration to say that the Hetch Hetchy controversy had awakened the nation.

The wilderness movement in the United States continued after Muir s death in December 1914. The appreciation for the spiritual aspect of wilderness was most notably

continued by Aldo Leopold (*see* **Leopold, Aldo**, Volume 5). In 1908 Leopold graduated from Yale School of Forestry, pursuing Gifford Pinchot's philosophy, only to reject his utilitarian view of nature. In summarizing the American approach to nature, he wrote ••• a stump was our symbol of progress . Although Leopold became president of the Ecological Society of America (founded in 1915), his largest contribution to the environmental movement was through his writing. His most influential legacy, *A Sand County Almanac and Sketches from Here and There* was published in 1949.

WILDLIFE PROTECTION MOVEMENT

While the environmental movement took root in North America through wilderness campaigns, the movement also expanded in Europe through the latter part of the 19th century. Lacking vast tracts of wilderness, the focus of nature lovers was the protection of animals. As early as 1824, the first organization concerned with non-human life was established in England by philosopher Jeremy Bentham. The British Society for the Prevention of Cruelty to Animals championed the protection of domesticated animals. It was not until 1903 that the fate of wild species found an organizational champion, the Society for the Preservation of the Wild Fauna of the Empire.

In 1900, a treaty was negotiated by the foreign ministers of colonial powers controlling the continent of Africa and signed in London the Convention for the Preservation of Animals, Birds and Fish in Africa. *The Times* of London's coverage of the conference included a decidedly environmental message

> The advance of civilization, with its noise and agitation, is fatally disturbing to the primitive forms of life. Commerce, moreover, discovers continually some new demand for the trophies of the chase. The horns, the skins, and the plumage of the beasts and the birds have an increasing market value. It is not surprising, therefore, that men of science have become alarmed at the prospect of the extinction of the most interesting and characteristic types of zoological development.
>
> (Bonner, 1993)

But it was not only scientists who worried about the perilous fate of Africa's wildlife. The colonial dukes and lords and princes had come to regard the hunting of African game as their private domain. In 1903, the colonial big game hunters founded the Society for the Preservation of the Wild Fauna of the Empire. In the media, they were dubbed penitent butchers. These conservationists were not discouraged from killing lions under the terms of the 1900 treaty. The treaty actually called for protection only of those species which are either useful to man or are harmless . Hunting lions, leopards, hyaenas and wild dogs was consistent with the treaty. Conservationist US President Teddy Roosevelt was one of the big game hunters hosted by British residents of East Africa. In a remark that highlights the different strands of the fabric of the environmental movement, when hiking through Yosemite, Muir had chastised Roosevelt for his love of hunting: Mr Roosevelt, when are you going to get beyond the boyishness of killing things ••• are you not getting far enough along to leave that off?

The hunter conservationist remains an important part of the modern environmental movement, found in groups such as the National Wildlife Federation in the US, its related Canadian Wildlife Federation, and Ducks Unlimited. Although now quite removed from hunting, the original founders of the World Wildlife Fund (WWF), which came into being in the 1960s, had come from similar origins.

After the devastation of European human environments, Briton E M Max Nicholson worked to establish the first international conservation organization with goals beyond Africa. The International Union for the Conservation of Nature (IUCN) came into existence in 1948, through the work of Nicholson and others (*see* **IUCN (The World Conservation Union)**, Volume 4). Staffed by scientists, it established a reputation for credible and authoritative conservation research. Working with government and non-government members, IUCN (now known as the World Conservation Union) had a unique ability to influence government policy. Still, it lacked the wherewithal to raise funds for its program. To meet this need, the WWF was founded.

Public sentiment had been moved through the influential writings of Sir Julian Huxley, scientist and first head of the United Nations Educational, Scientific and Cultural Organization (UNESCO). Huxley wrote a three-piece series in *The Observer* in 1960 describing his travels though Africa, the magnificent wild creatures and inexorable push toward their destruction. It moved Nicholson and other committed entrepreneurs to organize a fund-raising and campaigning arm for IUCN. IUCN and WWF were in partnership until WWF broke away to do its own work in the mid-1980s. (In the 1990s, the WWF officially changed its name to the Worldwide Fund for Nature.) The early connections between wildlife appreciation and royalty are maintained by WWF through the active roles of Their Royal Highnesses, Prince Philip and Prince Bernhard of the Netherlands.

Key elements of an international environmental movement were in place by the middle of the 20th century, with factions concerned with wilderness preservation, conservation of natural resources, including wildlife for sustained use, and wildlife protection, fighting to keep species from going the way of the dodo. The movement had extended itself through much of the globe, although headquarters and impetus for action largely came from the source of the damage; the industrialized world.

THE MODERN ENVIRONMENTAL MOVEMENT

Most writers date the modern environmental movement's birth as 1963 when Rachel Carson's classic *Silent Spring* was published (*see* next section and Carson, Rachel Louise, Volume 5). It is no doubt true that a new type of organization was required to tackle a new host of environmental threats.

The by-products of warfare were changing the very nature of the environment. World War I gave the world chlorine compounds; World War II yielded chlorinated hydrocarbons, organophosphates, and increased radiation from the new technological ability to split the atom, for armaments and electricity. Pollution from industrial enterprises was compromising regional air quality and killing life in aquatic systems. The new chemicals brought new health risks. While the chlorine compounds and other toxic chemicals found commercial application as pesticides, the arms race led to global contamination with fallout from atmospheric testing and increased radiation from the nuclear power industry. It is clear that a prime motivation for widespread public protests against atmospheric nuclear weapons testing was the impact on public health, particularly on children's health, around the world.

A new type of international organization was born out of the movement to stop atmospheric testing. Although the campaign is usually characterized as part of the peace movement, it had all the hallmarks of environmental concerns. Nuclear testing was distributing tons of toxic radionuclides, including strontium-90, all around the world. Strontium-90's pathways mimic those of calcium. Taken up in grasses, consumed by dairy cows, the radiation made its way to milk. Once consumed, it was stored in bones and teeth, increasing the risk of childhood leukemias and later adult cancers.

In response, the world saw its first truly global grassroots movement in the late 1950s. Many of the groups were established by mothers concerned about nuclear weapons testing and the threat to their children. Although national groups of many different names were established, the largest umbrella, the Campaign for Nuclear Disarmament (CND) organized the key global events. The organization was aided by the prominence of one of its founders, Lord Bertrand Russell. The ubiquitous nature of its incorporation into popular culture can be seen to this day in the use of its symbol as the peace sign. The circle with a semaphore was the symbol for the letters CND.

In the US, the campaign against atmospheric nuclear testing was organized through the Committee for a Sane Nuclear Policy, generally abbreviated to SANE. Key board members included the leading liberal thinkers of the day: editor of the *Saturday Review* Norman Cousins, repeat candidate for president, Norman Thomas, and the author of the best-selling book, *Baby and Child Care*, Dr Benjamin Spock.

The Ban-the-Bomb movement held large marches, launched petition drives, and enlisted celebrities and Nobel laureates in its campaign. In the UK, an annual Easter-time march built public support and momentum. The march started in 1956 when a single Quaker walked from London to a military research facility at Aldermaston, a distance of 54 miles (87 km). The following year, 100 people marched. By 1959, there were 3000 marchers. But, the most celebrated and successful march was in 1960 when over 100 000 marchers made the journey towards London from Aldermaston, culminating with a giant rally at Trafalgar Square. Marchers came from national groups from around the world, with committees from Ghana, South Africa, Greece, Israel, Cyprus, the US, Canada, Ireland and France. The line of the march stretched a distance of ten miles (16 km), Marchers were applauded by supporters along the sidelines, and Musicians played along the route. An enormous volunteer effort orchestrated lodging en route, mostly on school and church floors, and canteen wagons served three meals a day. The youngest marcher, Martin Dowling, was seven weeks old. The eldest, in a wheel chair, was nearly 100. The march was led by Canon Collins, the canon of St. Paul's Cathedral and by Jacquetta Hawks, historian, wife of J B Priestley. Many Labour members of parliament marched as well. The Aldermaston March of 1960 was a major media event, covered by television and radio news around the world. If Woodstock had happened first, it would have been dubbed the Woodstock of the Ban the Bomb movement.

The grassroots political movement was rewarded when in September 1963, the governments of the United States, the Soviet Union and the UK entered into the Nuclear Test Ban Treaty. The treaty banned the testing by detonation of nuclear weapons in the atmosphere. While the treaty is often characterized as part of the developing movement for non-proliferation and peace, it spoke most immediately to ending the widespread dispersion of nuclear contamination through the atmosphere.

The Test Ban Treaty was not the first multilateral agreement to deal with an environmental concern. The early part of the 20th century also saw a number of binational treaties between Canada and the United States; first the 1909 Boundary Waters Convention, which created the International Joint Commission, and the Migratory Birds Convention. But the Test Ban Treaty was arguably the first created in global fashion and resulting from the efforts of NGOs.

SILENT SPRING

The modern environmental movement is usually traced to the publication of *Silent Spring* by Rachel Carson (Carson,

1963) (*see* Carson, Rachel Louise, Volume 5). *Silent Spring* chronicled the health and environmental threats of the escalating and widespread use of chemical synthetic pesticides. The book was both well written and well researched and became a bestseller. Despite the vociferous efforts of the chemical lobby to attack the credibility of Rachel Carson, she became a hero to many Americans. Her warnings led to the creation of new citizen groups working to have certain pesticides banned. Efforts in Long Island, NY to ban dichlorodiphenyltrichloroethane (DDT) led to the creation of the Environmental Defence Fund (*see* Environmental Defense Fund, Volume 5). Traditional groups, such as the Sierra Club, now under the leadership of its first executive director, David Brower (*see* Brower, David, Volume 5), broadened the organization's mandate to tackle pollution and pesticides.

Through the late 1960s, a huge increase in environmental awareness burgeoned in the US. In some ways, it could have been seen as an extension of the movement against the war in Vietnam. But within the political debate taking place in the US, the new environmental movement was often accused by the anti-war movement of being safe, white, and middle class,' detracting from the tougher issue of predominantly black US soldiers drafted to fight an unpopular war in Southeast Asia. Still, both movements grew in strength.

In the fall of 1969, the US government planned to conduct an underground nuclear test in Amchitka, Alaska, and suddenly a new protest movement was sweeping the US to stop the test. Scientists feared that the blast might actually destabilize an area with significant fault lines, with the potential for a catastrophic earthquake. The US Secretary of Defense took his whole family to Alaska to demonstrate his faith in the safety of the nuclear test, but opposition mounted. US President Richard Nixon was besieged with telegrams and letters urging that the test be cancelled. The grassroots opposition also came from north of the border, where a small group in Vancouver organized themselves as Greenpeace to oppose the tests. The test proceeded, but the movement for environmental protection was growing.

In 1970, *Life* magazine ran a cover story, Lake Erie is Dead. The Cuyahoga River in Ohio had caught fire from the chemicals that had been dumped there by local industries. The emblem of the US crest, the mighty bald eagle, was near extinction due to the pernicious effects of DDT as it moved through the food chain. The reproductive success of the bald eagle, as top predator, was dangerously compromised.

The growing movement was harnessed by Denis Hayes and US Senator Gaylord Nelson in a national teach-in called Earth Day (*see* Earth Day, Volume 5). April 22nd, 1970 galvanized a new and modern movement for environmental protection. Earth Day was officially recognized by Presidential Proclamation from US President Richard Nixon. Large corporations seeking public favor, from Coca Cola to Proctor and Gamble, endorsed the event. Tens of thousands of people participated from coast to coast, with limited activities in Canada as well.

Meanwhile, the environment movement was increasing in Europe as well. In the UK, the International Institute for Environment and Development (IIED) was formed and championed by the visionary Barbara Ward (*see* Ward, Barbara, Volume 4). David Brower, having left Sierra Club, founded Friends of the Earth (FoE) in 1969 (*see* Friends of the Earth, Volume 5) and affiliate FoE groups were formed in Europe and elsewhere. Greenpeace, also, was forming national groups around the world. As well, local grassroots efforts for environmental protection were being organized in many countries.

STOCKHOLM

The gathering strength of public concern for the environment was recognized by the UN in the first Conference on the Human Environment, in 1972 in Stockholm. The UN conference is remembered for its adoption of the Stockholm Principles for Environment as well as for the North–South split. Brazil boycotted the conference, believing that the industrialized world's environmental agenda was code for stalling development in the developing world. Yet, the conference was, by any measure, a success.

Secretary general for the conference, Canadian Maurice Strong, immediately sensed the need to include the environmental movement. Under UN terminology, such citizens' groups were called NGOs. The organizing of a parallel NGO conference for Stockholm was a first of its kind. Maurice Strong also commissioned a popular non-official book for the conference. *Only One Earth: The Care and Maintenance of a Small Planet*, by Ward and Dubos (1972), contributed to a growing global environmental consciousness. Surprisingly, it became a bestseller and was printed in twelve languages. Speaking to the NGO conference at Stockholm, US anthropologist Margaret Mead, in what would become a motto for environmental groups for generations to come, said Never doubt that a small group of committed people can change the world. Indeed, it is the only thing that ever has .

The years leading to the UN Summit in Stockholm and those immediately following saw the mainstreaming of environmental concerns. Governments at all levels created departments of the environment. New pollution control legislation was brought forward in countries around the world. In the US, legislation included the National Environmental Protection Act which established environmental assessment, the Clean Air Act, the Clean Water Act and the Endangered Species Act.

The first major wave of environmental activism receded in response to the apparent acceptance by government and corporations of the demands of NGOs. Alternatively, the oil shock of the early 1970s has been credited with dampening demands for environmental protection. Still, the oil crisis instilled an ethic of energy conservation, if briefly, in the psyche of Americans and Canadians. Major auto manufacturers moved to produce more energy efficient cars. Amory Lovins promoted soft energy paths and demand-side energy management. The energy conservation movement led to the creation of a new type of environmental NGO, one concerned with technological innovation for conservation and renewable energy sources.

Environmental groups grew around the world in response to increased pressure on natural spaces and growing pollution. In Australia, the Conservation Society and other groups arose to stop the flooding of Lake Pedder, protect the Great Barrier Reef, the forests of Tazmania as well as to oppose uranium mining. Penan and Dayak indigenous people in Borneo organized with Malaysian environmental groups to call for protection of the rainforest, while in Brazil, rubber tappers, known as *seringueiros*, organized for economic rights as well as protection of the Amazonian rain forest. In December 1988, seringueiro leader, Chico Mendes, was murdered just outside his Xapuri home, despite the presence of state-provided bodyguards. In India, women organized to protect forests through the Chipko movement (*see* Chipko Movement, Volume 5), while in Kenya, Wangaari Mathai organized the planting of trees through the Greenbelt Movement. Even within the totalitarian system of the USSR, voices of environmental activists were heard.

New environmental threats through the next few decades created focused campaigns for change. In the mid-1970s, the thinning of the ozone layer led first to consumer campaigns to avoid those cosmetic products using ozone-depleting clorofluorocarbons (CFCs). As consumers, primarily in the US and Canada, stopped buying products containing CFCs, the manufacturers stopped using them, hailing their commitment to environmental protection. It was not for another decade that citizens realized CFC use had continued and expanded through use in other products, from air conditioning to blown foam insulation. Governments responded to powerful environmental NGO campaigns in global negotiations leading to the Montreal Protocol in 1989. Friends of the Earth International (FoEI) was particularly associated with this campaign as was the Washington, DC, based Ozone Action. By that time, the role of NGOs within high level negotiations had grown. NGO representatives were included within the delegations of many industrialized country governments. NGOs spoke from the floor in plenary, as well as dominating the streets in demands for change.

BRUNDTLAND TO RIO

In the last years of the 1980s, the second major wave of public environmental activism was cresting. It happened to coincide with the hearings of the UN sponsored the World Commission for Environment and Development (WCED or more commonly known as the Brundtland Commission). The WCED was chaired by the leader of the Norwegian parliamentary opposition, Dr Gro Harlem Brundtland. But, when the government in power fell, newly anointed Prime Minister Brundtland did the unexpected: she remained chair of the commission. Other commission members included the former secretary general of the Stockholm Conference Maurice Strong, Ambassador Mohamed Sahnoun of Algeria, Guyana's Shridath Ramphal, the secretary general of the Commonwealth of Nations and the Deputy Prime Minister Mansour Khalid of the Sudan, to name a few of the 22 members.

Unlike other groupings of prestigious and powerful personages pulled together in major commissions, the Brundtland Commission held public hearings around the world. In Indonesia, Brazil, Norway, Zimbabwe, Kenya, the USSR, Canada, Japan, they sought out the views of indigenous peoples, peasant farmers, and NGOs of all shapes and sizes. Hundreds of individuals and groups presented their views on environment and development to the Commissioners. In the process, the role of NGOs and the political space they occupied was expanded. The WCED report, *Our Common Future*, was released in 1987, many of its pages reflect a recognition of the role of NGOs as important catalyst for the emerging concept of sustainable development.

One of the key recommendations of the Brundtland Commission was for a major global conference on the linked problems of environment, development and militarism. The WCED recommended that a UN Summit be convened in 1992, marking 20 years since Stockholm. That advice led to acceptance by the UN General Assembly of a global conference focusing on environment and development. Militarism was dropped from what the Brundtland Commission termed a three-legged stool. The UNCED was held in June 1992 in Rio de Janeiro, Brazil; thus improving prospects for bridging the North–South divide that led to Brazil's 1972 Stockholm boycott.

The Rio process expanded the role of NGOs in multinational issues. The negotiations at the first Preparatory Committee (Prep Com) meeting, held in Nairobi, Kenya in August 1990 were delayed for several days until the issue of the scope of NGO participation rights could be resolved. Hard-line opposition to opening the process of negotiations nearly stymied the effort for greater transparency. But, in the end, the issue was resolved in favor of previously unknown opportunities for NGO contribution to global policy development. NGOs, whether those traditionally accepted within the UN Economic and Social

Council (ECOSOC) bureaucracy or not, would be permitted to speak in plenary at the discretion of the chair and attend most working group negotiations. The advent of electronic communication, via the internet, engaged many more NGOs around the world. Experimental efforts at early Prep Coms evolved by the time of the Earth Summit into a well respected daily bulletin of the progress of negotiations, distributed in paper form, but simultaneously, around the world. Earth Negotiations Bulletin was a flagship project of Canada's International Institute for Sustainable Development.

NGO engagement in the Rio process led to a new level of policy awareness as well as international networking between and among NGOs. Targeted effort was made by northern NGOs to ensure that voices from the developing world were heard. Prominent and respected southern analysis from activists like India's Vandana Shiva, Malaysia's Martin Khor and Walden Bello of the Philippines group, Global South, reached a larger and wider audience. Martin Khor of the Third World Network in Penang had long worked under the spectre of potential political harassment and arrest. Through the course of the Rio preparatory process, his keen political analysis came to be appreciated by the Malaysian government. In time, even Malaysia welcomed NGO participation on its delegation.

By the time the Earth Summit was held in Rio in June 1992, thousands of NGOs from around the world had become engaged in the process. The NGOs, with the assistance of Maurice Strong who was once again secretary general of the conference, occupied substantial political space at the conference as well as holding a global forum, or peoples' response to the governmental process, parallel to UNCED. Strong also recruited Ecuadorian NGO leader, Yolanda Kakabadze, who went on to head the IUCN (now known as the World Conservation Union), to coordinate NGO relations for UNCED.

The women's movement became prominently involved in the Rio process through the efforts of the Women's Environment and Development Organization (WEDO), led by the indefatigable feminist and former US Congresswoman, Bella Abzug. Youth organizations became involved, as did aboriginal peoples.

Within the non-binding agreements for future action, known as Agenda 21, there was explicit recognition of the role of major groups. These were identified as environmental groups, development organizations, women's groups, youth and indigenous peoples.

RIO TO SEATTLE

Progress made in identifying NGOs, increasingly with other sectors labeled civil society, as legitimate agents of change deserving of political space in governmental affairs, was solidi ed in the ongoing work of the UN. The follow-up to the Earth Summit commitments: the Framework Convention on Climate Change, the Convention for the Protection of Biological Diversity, the Rio Declaration and the voluminous, 40 chapter, Agenda 21 all of these important documents were relegated to a new institutional body, set up within the UN backwater, the ECOSOC. The Commission for Sustainable Development (CSD) held annual reviews of progress in the spring of every year. NGOs continued to have substantial rights of participation. But little progress was being made in meeting the Rio targets.

The Rio Earth Summit produced a weak set of goals, and still weaker political will to achieve them. Annual CSD meetings offered ministers of environment the opportunity to share their frustration over their expulsion to the political wilderness. Every government had identi ed competing priorities that left the Earth Summit goals in the vast heap of the marginal and unloved. The reality was that Rio had emerged as the environmental wave of public awareness was already receding. Heads of government issued their Rio promises, went home and, for the most part, forgot them.

Other global summits continued to include signi cant NGO participation. In 1994, the International Conference on Population and Development (ICPD) met in Cairo. Issues of population and reproductive rights that had been pushed to the back burner in Rio were nally dealt with in Cairo. Large numbers of NGOs, many veterans of the Rio process, brought forward environmental concerns within the context of the political mine eld of population pressures. The Cairo Programme of Action explicitly embraced the work of the Earth Summit, two years before. It spoke to issues of unsustainable production and consumption, the need to ensure sustainable levels of consumption as well as the need to balance population numbers.

The year after Cairo, world leaders met in Copenhagen in March 1995 to negotiate commitments to improve the human condition. The World Summit on Social Development (WSSD) also recognized extensive rights of participation for NGOs. Within months, the UN was again hosting a conference (Beijing, September, 1996) the UN Fourth World Conference on the Rights of Women. This brought thousands of NGOs both to the of cial and, a now expected, parallel NGO conference. The documents from the Beijing Conference, the Beijing Declaration and the Beijing Platform for Action, were heavily in uenced by the lively North South debate of NGOs, from environmental, development, human rights and women s groups from around the world.

It can be argued that the seriousness of purpose of governmental enterprise is directly, and inversely, proportional to the extent of NGO participation. While NGOs received credentials and became accepted players in the Rio process, the real confrontation was in negotiations under the General

Agreement of Tariffs and Trade (GATT) within the decade long Uruguay Round. Aggressive trade liberalization was supported by abundant political will. By 1996, the Uruguay Round had succeeded in establishing a powerful, centralized enforcement and governance body, the WTO.

In retrospect, it is interesting how the two sets of global agreements, one to protect the planet's life support systems from the ravages of human activity, the other to ensure that human activity would not be impeded by any barriers such as troublesome environmental measures, could proceed side by side. With the same governments negotiating, there were no discussion within either process of the other. But there is no question which global vision had the upper hand. The WTO had teeth, the Rio agreements an impressive set of gums. Moreover, there were scattered references to the path to sustainable development through trade liberalization and the free flow of foreign direct investment throughout Agenda 21. In addition to targeting new areas for trade liberalization (the removal of trade barriers designed to protect domestic production from cheaper imports) the Uruguay Round set out to create an institutional home for the GATT, a global umpire of trade rules with extremely effective sanctions for any country violating the GATT.

Into this arena, there was no room for NGO engagement. The first ministerial gathering of the WTO, in Singapore in December 1996, offered NGOs observer status to the opening plenary of speech making. But the actual negotiations, in the WTO's own decision-making culture, left out not only NGOs, but most governments. Key agreement was reached on issues within small informal talks between the Europeans, the United States, Canada and Japan. Developing country diplomats could be found wandering the corridors and asking Martin Khor of the Third World Network if he had heard what was taking place behind the closed doors.

The Singapore meeting can be noted for one important decision. Developing countries managed en masse to block the introduction of an investment treaty into the WTO's deliberations. The efforts to accomplish a multi-lateral treaty to protect investors' rights intensified within the Organization for Economic Cooperation and Development (OECD). The treaty under negotiation was dubbed the Multilateral Agreement on Investment (MAI). Unexpectedly, opposition to what seemed an obscure bit of business in a little known international agency spawned a new and powerful international force, the anti-globalization movement.

In January of 1997, the text of the draft MAI was obtained by NGOs and placed on the internet. Public Citizen, a Ralph Nader founded organization in Washington, DC, played a prominent role in spreading information about the MAI from its web site. The text made it clear that, going beyond the position of dominance that trade had achieved through the GATT, the MAI would provide corporations with potential compensation for reduced expectations of profit. Word spread through the internet and through global gatherings, such as the corridors of the CSD meeting at the UN, that something new was afoot to further undermine environmental protection and domestic regulation. The OECD, which had promised a deadline of completed negotiations for spring 1997, moved the deadline to spring 1998.

Within governments, it appeared that little consensus had been reached between trade ministries and less powerful departments. In particular, ministries of culture expressed doubts about the MAI. The French Minister of Culture, in particular, openly criticized the homogenizing terms of treating culture like a product. The many aspects of society perceiving threats in the draft MAI text banded together in a new and broader coalition of environment groups, labor unions, development organizations, health advocacy groups, cultural organizations, educators, women's groups, and aboriginals. Opposition to the MAI spread globally in an unprecedented and grassroots fashion, aided by the internet.

OECD governments increasingly found themselves on the defensive domestically over support for a treaty to decrease nation state powers of regulation and increase private corporate rights. By spring, 1998, the announced deadline for completing the MAI, the negotiations collapsed. A new global movement experienced the power of democratic protest.

Parallel efforts had been under way for years to reform or shut down international financial institutions, such as the World Bank and the International Monetary Fund. Through the late 1990s the spectre of Third World Debt was also subject to a global campaign. Jubilee 2000 was initiated by church groups in the UK, but spread globally as well. Its call for reduction and removal of debt loads on heavily indebted, poor nations, led to improvements in debt cancellation by governments.

Into the simmering and now well-organized network of NGOs from around the world came the news in 1998 that the third ministerial meeting of the WTO would be held in the US, in Seattle, Washington. The news was a gift to a movement aware of its gathering momentum. Previous WTO ministerial sessions had been in Singapore and Geneva. Neither location is conducive to attracting large numbers of protesters. Seattle was an ideal location and groups around the world began to organize. Within the US, the key to fulfilling promises of massive demonstrations in Seattle was the support of the trade union movement, the American Federation of Labor-Congress of Industrial Organizations (AFL-CIO). Environmental groups, from Sierra Club to Greenpeace, animal welfare groups such as the Society for the Prevention of Cruelty to Animals, pro-democracy and trade groups, such as Ralph Nader's Public Citizen, began working with the labor movement, churches and a growing coalition of interests concerned about the

impact of economic globalization. Voices from the South also prepared for Seattle, and key thinkers and visionaries, like Martin Khor and Vandana Shiva, as well as hundreds of organizations began planning for Seattle. European activists, as well, made Seattle a focal point. Canadian anti-free trade campaigner Maude Barlow of the Council of Canadians, played a key role. By November 1999, over 50 000 people filled the streets of Seattle.

The reality is that the WTO was in trouble well before Seattle. The extent to which its rulings exceeded valid trade concerns led directly to a process of political delegitimization of the institution. There was a high level of public distrust as the WTO struck down environmental and health regulations. The trade ministers could no longer count on negotiating under a shroud of secrecy. Unlike the Uruguay Round, the political interest in the WTO process had now expanded beyond trade negotiators. The defeat of the MAI awakened ministers of other portfolios to the reality that trade negotiations were too important to be left to trade ministers. Globally, environment and culture ministers, in particular, were paying attention. They had to pay attention because the public and the news media no longer viewed trade matters as arcane. And because, after the defeat of the MAI, it was clear to a growing citizens' movement that global trade fights were winnable.

The negotiations in advance of the third ministerial meeting had not gone well. No progress had been made on a draft declaration for the ministers in over a year. Two weeks before the Seattle meetings, the preparatory talks in Geneva ended in failure. Intractable issues included agricultural subsidies, with the EU in violent disagreement with US plans to target its subsidies, as well as implementation issues, dealing with complaints mostly against developing countries that they were too slow in implementing the Uruguay Round. On these and other complex issues, there would be no prepared declaration. Everything would have to be negotiated on the ground in Seattle.

Two weeks before Seattle, invitations to world leaders and heads of government were quietly withdrawn. Of heads of governments, only US President Bill Clinton would attend. And, as it turned out, he embraced the protesters' demands for core labor standards. It was the *coup de grace* that ensured no agreements would take place in Seattle.

The street demonstrations and police over-reaction will be the lasting images of Seattle. But as an exercise in citizen political strength, Seattle is much more significant for the growing strength of NGOs. The NGOs involved had developed a strong critique of the current threats of increased corporate rule. They coordinated across huge distances and raised awareness within their own countries. The culminating days of teach-ins and protests in Seattle further increased media coverage and global public identification of a new and previously obscure institution, the WTO.

CONCLUSION

For more than a century, environmental groups have played a major role in evolving governmental and societal responses to the human-caused degradation of our natural world. NGOs have scored many significant victories: from national parks and protection for endangered species, to global treaties to protect the ozone layer, and end nuclear testing. Individual toxic substances have been banned through NGO campaigning and new technologies with reduced environmental impacts have been embraced more quickly.

In the process, many environmental groups have become themselves bureaucratized and seen as part of the mainstream. Despite victories in individual cases, ecological integrity is everywhere threatened. Global environmental health is significantly worse now than at any time in human history.

NGOs have, however, continued to provide an essential watchdog and public education function in every nation on earth. It can be argued that as the role of governments and the nation state itself is shrinking, the role of NGOs is expanding. Civil society, at a global level, is organizing in new ways. Democratic expression as a counter balance too, increasingly powerful, private sector interests is a different role for NGOs than lobbying parliaments for governmental action. NGOs will likely continue to occupy an increasing area of political space as the challenges of global environmental change weaken existing institutions.

Environmental Philosophy: Phenomenological Ecology

Ingrid Leman Stefanovic
University of Toronto, Toronto, Canada

In many respects, industrialized society perceives problems of ecology and human dwelling to be technical matters of environmental and architectural management. No less important, however, are assumptions that shape the way that we frame environmental research, policies and programs. How we perceive and implicitly evaluate our built and natural environments in uence the questions we ask as well as the solutions we propose in matters of ecology and human settlement planning.

Environmental philosophy explores precisely such issues of how we understand and value our built and natural worlds. Within this eld, phenomenology - the investigation of hidden structures of experience - has a distinctive role. Rather than construct abstract, speculative ethical theories, the phenomenological method aims to illumine tacit paradigms and worldviews that underlie our relationship with the environment. For example, studies of the impact of the automobile on the environment typically investigate technical matters such as frequency of car use or degree of degradation of agricultural lands. The phenomenologist's contribution to the discussion arises from a concern to uncover tacit elements of human experience that subtly but effectively inspire our strong emotional ties to the car. In the absence of an understanding of peoples' values, loves and modes of behavior, technical solutions may be dif cult to implement. To explore implicit patterns of meanings that condition our everyday behavior becomes a central concern of environmental phenomenology or, as some have coined the eld, phenomenological ecology.

PHENOMENOLOGY IN A CALCULATIVE ERA

Of pivotal and major importance to the field has been the work of German phenomenologist Martin Heidegger, who distinguished between two kinds of thinking in the Western, metaphysical tradition: calculative and originative (Heidegger, 1966). *Calculative thinking* is linear, goal-directed and essentially quantitative, seeking maximum efficiency in its control and mastery of discrete, empirically defined entities. *Originative thinking* examines the foundations of calculation, by investigating not just things but relations between things. Such thinking requires openness to the deeper mysteries of existence that are more than mere logical puzzles to be calculatively ordered.

We have become particularly expert in calculative thinking and, in most cases, we equate calculation with genuine thinking *per se*. Such thinking computes ever new, ever more promising and at the same time more economical possibilities, racing from one prospect to the next (Heidegger, 1966, 46). Specifically result-oriented, calculation seeks to organize individual facts and entities with a goal of maximum efficiency, dexterity and control. In such a scenario, the world appears as a collection of discrete objects subject to human command. Nature becomes a gigantic gasoline station that we envision is ours to tame and direct (Heidegger, 1966, 50–51).

Such a reductionist interpretation of the meaning of thinking arises from within a historical tradition that primarily concerns itself with empirical, quantifiable realities, rather than some foundational, qualitative issues that exceed such quantitative measures. An atomistic analysis of beings (referred to by phenomenologists as *ontic analysis*) takes precedence over any inquiry into the mystery of Being itself (that is, ontological inquiry). Calculative thinking assumes that which is subject to measurement and quantification is real and actual. Material entities, as well as ideas and concepts that can be categorized and delineated in the clear and distinct fashion of bounded entities, are implicitly valued above all else. At the same time, *positivism* – the theory that knowledge is based on natural objects and properties that can be verified by the empirical sciences – gains prominence in a calculative era that assumes that only clearly bounded, materially evident entities are real.

When positively existing entities acquire such precedence, nebulous phenomena such as relationships or negations that cannot be seen as fully present consequently are not subject to serious management. In its fascination with things, our era becomes oblivious to the significance of any phenomena that cannot be secured through measurement, or categorical control. Favoring calculative parameters, originative thinking is obscured and forgotten as a genuine possibility of reflection.

Why is this forgetfulness of relations, negations and voids at all important to environmentalists? Consider first how the modern, positivist worldview interprets a particular negative phenomenon of absence, in a case of blindness or not seeing. St. Thomas Aquinas articulated an interpretation of this privation that is symptomatic of the calculative paradigm (Barrett, 1958). Aquinas appropriated an Aristotelian perspective that distinguished between *ens reale* (real Being) and *ens rationis* (conceptual Being). On this understanding, the cataract on the eye is real, because it can be empirically measured and it is an actual, positive entity. On the other hand, while blindness can be said in some sense to exist, as the *absence* of sight, it *is* only conceptually.

The problem with this interpretation, however, is that it downplays the experiential significance of the phenomenon of blindness. The philosopher William Barrett points out that for the man whose life has suddenly been thrown into

complete darkness, non-seeing, a privation, has descended on him with more crushing effect than brick from a rooftop (Barrett, 1958, 288). To reduce the depth of this experiential significance to the status of mere conceptual Being denigrates the human cost of such loss of sight and, to this extent, has to be philosophically misplaced as well. Nevertheless, strange as it may seem, in a tradition that assigns reality only to positively existing entities, the absence of sight can only be defined in terms of a conceptual truth. The alternative is to subject the phenomenon of blindness to a reductionist paradigm whereby it is circumscribed wholly within the presence of a material object – a cataract.

Analogously, one might imagine how the calculative worldview assigns value to a clear-cut forest. What matters is the timber resource, extracted and manufactured into positively existing entities for human use. Proceeding within a management scenario driven by economic utility, of far less value are the nebulous and too-complex-to-measure impacts on ecosystem functions, processes and relationships. The original forest matters only to the extent that it is a positively existing resource, or else that it exists conceptually in the mind as a fond but overly romanticized image or memory.

The philosophical paucity of the calculative paradigm arises once again when one considers the human impact of involuntary displacement. My home is expropriated and I am required to move to another location. Technically speaking, as my house is bulldozed, it is no longer. Is its significance merely to be relegated to the level of a fleeting memory or conceptual reality?

The trauma of involuntary displacement clearly can indicate more than the physical destruction of a house. Instead, it may mean the end of a whole way of life and a radical de-centering of my very being. The fact that Western society no longer engages in the large-scale displacements of the 1960s' urban renewal programs indicates that, implicitly, we know that the absence of home means significantly more than the destruction of a material object. Rather, the loss affects us deeply in terms of our very sense of place. In fact, we are beginning to sense that we interpret our built and natural environments, not merely in terms of reductionist categories but, more primordially, from a more complex, holistic perspective.

POSSIBILITIES OF ORIGINATIVE THINKING

It may appear that the obvious alternative to reductionist, calculative thinking would be a form of holism. Environmentalists themselves increasingly advocate precisely such an alternative. For instance, the Brundtland Commission emphasizes the need to integrate economic, socio-cultural and environmental concerns, building on the ecologist's widely accepted recognition that the whole is greater than the sum of its parts .

While these appeals can be quite compelling, ecoholism is hardly unproblematic. It may well be true that everything is ultimately connected in some way to everything else. Philosopher David Cooper has a point, however, when he notes that it is without interest and moral implication that a falling tree in Australia has some connection with the birth rate of flies in Alaska; and it is false if it is meant that such connections must be detectable, let alone significant (Cooper, 1992, 166). How broadly is the holistic net to be legitimately thrown if it is to be practically and morally relevant?

Other problems with the holistic alternative also arise. If the whole is greater than the sum of its parts, does that conclusion relegate the individual parts to a lower status on the moral hierarchy? Environmental philosopher Tom Regan files this charge of eco-fascism against holistic thinking. Holistic philosophers who argue that one is justified in sacrificing individuals in order to preserve other species or the integrity of ecosystems are subject to this charge of fascistic rule of whole over parts.

Another major difficulty with advocating holistic thinking as an alternative to calculation relates to the problem of definition. Amidst the growing sentiment that environmental problems require holistic, interdisciplinary solutions, there are calls for the development of more comprehensive indicators of sustainability. The World Bank proposes an Index of Sustainable Economic Welfare (ISEW) (*see* ISEW (Index of Sustainable Economic Welfare) and GPI (Genuine Progress Indicator), Volume 5) to measure gross domestic product but to include natural and social parameters as well. President Clinton's Council on Sustainable Development called for the creation of a number of new economic, social and environmental quality indicators. Again, however, the question arises: does holism mean simply throwing a wider net around discrete entities to accumulate an ever-larger inventory of indicators?

From a phenomenological viewpoint, these efforts to describe a holistic alternative to positivism remain philosophically problematic because they remain immersed within the calculative paradigm. To say that everything is connected to everything else remains focussed on individual, discrete entities that may (or as Cooper points out, may not) be meaningfully interconnected in some way. These efforts do not call for a genuinely different kind of thinking than the calculative that simply seeks to amass a great many individual things in a broader web of significance.

The same problem occurs with accumulating a larger array of indicators, under the guise of interdisciplinary thinking. Genuinely holistic approaches must do more than simply collect an ever-increasing number of entities, if the phenomenologist's call for an alternative to calculation is to be heeded. Finally, in deference to Regan's criticisms, holistic thinking must accomplish more than a grand synthesis or construction of a Super-Part, bigger and better than the individual parts beneath it.

How do we genuinely move beyond calculation, once we recognize that reductionist versions of positivism fail to capture the increasing complexity of environmental problems? Phenomenology offers an alternate vision. The originative, ontological thinking that Heidegger proposes is grounded in *hermeneutics*, the art of interpretation of texts. If we try to read as a word a conglomeration of letters, e.g., *rgonaci* – and then rearrange the letters as *organic*', the second reading generates more than a mere re-configuration of individual letters. On the contrary, in the latter case, an implicit order now recognized among the letters allows for a shift in the act of interpretation that reveals the meaning of the word as a whole.

In fact, when we read a text, the understanding consistently interprets holistically, although we may not be explicitly aware of this fact. Consider how reading requires something different than the accumulation of individual words on a page. The experience of reading is more than merely additive, in that I do not simply store up a linear series of individual words so that, at the end of the sentence, I compute the series into a meaningful totality. Rather, the hermeneutic experience reveals an interplay between the significance of the text as a whole, and its progressive illumination through its parts – words, sentences and paragraphs. Because reading is other than merely summative or sequential, it offers a particularly revealing, everyday example of how understanding is holistic, where the whole means something intrinsically other than a superpart (Bortoft in Seamon and Mugerauer, 2000).

In this respect, Heidegger distinguishes between the totality that we analytically or sequentially construct and the wholeness of the world that is more subtly, tacitly revealed to the understanding. The world itself is much more than something subsequent that we calculate as a result from the sum of all beings. The world comes not afterward but beforehand, in the strict sense of the word ••• Instead, it is so self-evident, so much a matter of course, that we are completely oblivious to it (Heidegger, 1982, 165).

The task for ontological thinking, then, becomes one of illumining how we are in-the-world immediately, prethematically – meaning prior to the reductionist move of defining and segregating discreet entities from the referential context within which they find their place. Originative thinking will aim to uncover the underlying conditions of the possibility of calculation and the scientific analysis of discreet entities. In that case, the question to ask is: how might such a phenomenological undertaking affect our inquiries into the meaning of our built and natural environments?

RETHINKING SENSE OF PLACE

When Heidegger urges us to re-evaluate the calculative paradigm, he invites us to think meditatively or originatively, which is to say to raise anew the question of the meaning of Being. Rather than investigating individual entities in isolation–either the human subjectivity or objective environmental conditions – he urges us to reflect upon the relation between human beings and the places wherein they dwell. We are more than simply isolated subjectivities but are in-the-world, the hyphenation emphasizing an essential belonging of human beings to their environments. To inquire about how we are in-the-world, prior to artificially separating and reifying subjective and objective entities, entails a different kind of ontological thinking that is less concerned with beings than Being itself.

How might we ontologically and phenomenologically describe the way in which we *are* in the world? Heidegger believes that, fundamentally, the way in which you are and I am, the manner in which we humans *are* on the earth, is *dwelling*. To be a human being ••• means to dwell (Heidegger, 1971, 147). When we build our settlements, we do not simply erect physical constructions of particular proportions. Nor is it enough to say that buildings can be more meaningfully described as cultural symbols or that they possess social, economic or technological significance on top of their material substantiality.

Phenomenologist Gaston Bachelard points out that the lived experience of our environment is of more than mere physical artifacts. A house that has been experienced, he writes, is not an inert box. Inhabited space transcends geometrical space (Bachelard, 1964, 47). Similarly, in describing human beings as dwellers, Heidegger wants to say that built spaces are neither mere external objects nor social constructs but rather, spaces open up by the fact that they are let into the dwelling of man ••• Dwelling is *the basic character* of Being in keeping with which mortals exist (Heidegger, 1971, 157, 160). Noel Arnaud's simple but pointed remark captures these insights succinctly: I am not merely contained within space, but on the contrary, Je suis l'espace où je suis. (I am the space where I am) (Bachelard, 1964, 137).

One's fundamental comportment in-the-world is defined by Heidegger in terms of a spatializing and temporalizing activity of understanding and a primordial engagement with a world that is itself more than a static entity. Why, then, is the relationship between humans and their world not simply one that can be defined as a correspondence between two static, present-at-hand entities? Heidegger asks his readers to consider a common example of how we relate to our environment. As I head toward the door of a lecture hall, I am already there and I could not go to it at all if I were not such that I am there. I am never here only, he argues, as this encapsulated body; rather, I am there, that is, I already pervade the room and only thus can I go through it (Heidegger, 1971, 156–157).

Poet Pierre-Jean Jouve reiterates this thought when he writes: Car nous sommes où nous ne sommes pas. (For we are where we are not) (Bachelard, 1963, 211). Certainly, we exist among positively existing entities but our way of being among those entities includes a holistic engagement with a broader, referential context that, as nothing particular, nonetheless opens up the condition of the possibility of entities appearing as entities. This relation of human beings in-the-world moves beyond an engagement with speci c things to include the more mysterious, incalculable ontological phenomenon of dwelling and what others beyond Heidegger have come to refer to in terms of a sense of place (Mugerauer and Relph in Seamon and Mugerauer, 2000).

Philosopher Edward S. Casey maintains that to exist at all as an event is to have a place to be implaced ••• The point is that place, by virtue of its unencompassability by anything other than itself, is at once the limit and the condition of all that exists (Casey, 1993, 13, 15). How we are in the world, in the most primordial sense, is as emplaced. Architect Christian Norberg-Schulz suggests that spirit of place is a qualitative, total phenomenon that cannot be reduced to any single property without losing its concrete signi cance.

On such an interpretation, natural and built places are more than mere geographical locations along geometrically de ned parameters. Phenomenologically understood, the experience of dwelling is much more rich, diverse and engaging than can be captured in any reductionist catalogue of entities. A key element of phenomenological inquiry relates to how entities belong together in place as well as how we might better encourage that sense of place through more sensitive design and policy-making. Heidegger maintained that the Western, metaphysical tradition has slipped into a forgetting of the question of the meaning of Being and, at the same time of necessity, this forgetfulness has compromised our understanding of the meaning of dwelling and being-at-home in our natural and built worlds. The task remains to see how we might further investigate this forgetfulness and seek a more balanced relationship with the places that we inhabit.

PHENOMENOLOGICAL METHODS OF INVESTIGATING NATURAL AND BUILT PLACES

Within a calculative frame of reference, one interprets the notion of method as a logical, linear process of reasoning that demands that speci c steps be followed, in order that de nitive results are achieved. In marked contrast to the calculations of positivist science, Heidegger tells us that the phenomenological, scienti c method is never technique. As soon as it becomes one, it has fallen away from its own proper nature (Heidegger, 1982, 21). Originative, phenomenological interpretations will involve something other than a how-to manual or a transparent, technical delineation of discrete rules. What announces itself within a phenomenological notion of method is a more iterative, process-oriented approach to investigating entities and the underlying ontological conditions of their appearance.

Yet Heidegger does concede that there are three basic components to the phenomenological method: reduction, construction and destruction (Heidegger, 1982, 19). For us, phenomenological reduction means leading phenomenological vision back from the apprehension of a being ••• to the understanding of the Being of this being (Heidegger, 1982, 21). Since ontology is de ned as an inquiry into the meaning of Being, phenomenology is ontology. Methodologically, a key concern will be to nd ways to illumine a holistic, ontological vision of the phenomenon under investigation, rather than to merely catalogue individual, discrete moments.

At the same time, phenomenologists know that Being does not become accessible like a being. We do not simply nd it in front of us (Heidegger, 1982, 21). More than a merely negative methodological measure that opposes beings, phenomenology requires that we should bring ourselves forward positively toward Being itself in a free projection and in engaged, phenomenological construction . That such a move is more than a merely arbitrary, subjective projection is ensured by a methodology that includes a destruction , that is, a critical process in which the traditional concepts are deconstructed down to the sources from which they were drawn (Heidegger, 1982, 23). Underlying traditions and taken for granted patterns of understanding are thereby laid bare.

In short, it seems that the phenomenological method will seek to move from an investigation of beings, to a reduction to ontological grounds. Such a move will do more than relinquish individual entities altogether, but instead will require a special comportment and constructive engagement with the world an engagement that demands a free projection that is both creative and originative at the same time. Finally, as a destruction or dismantling of those arti ces that conceal originary meanings, the phenomenological method will seek to uncover the tacit sources of the traditions that sustain our ways of thinking and the holistic context wherein our questioning is grounded in the rst place.

Accepting such an understanding of phenomenology, one is still drawn to ask: how do these components translate into actual investigative procedures for the study of built and natural environments? How do we study concretely and holistically the manner in which we are emplaced in-the-world, without compromising the ontological endeavor?

One strategy for illumining ontological presuppositions of dwelling consists of a deconstruction of place-based narratives. While common methods of investigating perceptions and values include such tools as standardized questionnaires, the phenomenologist believes that such thematic approaches by definition cannot accommodate the complexity of prethematic presuppositions that are taken for granted before we conceptualize specific responses. Rather than reify peoples' perceptions within preconceived frameworks and parameters constructed in advance by researchers, phenomenological interview techniques lean toward less structured approaches to uncovering perceptions of place. In the words of philosopher Jim Cheney, the deconstruction of spontaneous narratives encourages us to avoid totalizing discourse and the top-down imposition of universal, preconceived theories as we collectively seek to tell the best stories we can to uncover our communities storied residence and local, bioregional truths. The phenomenological task is to illumine from the ground up, so to speak, holistic visions of place that emerge from spontaneous, unstructured narratives of peoples' lived experiences.

Other phenomenological strategies seek to describe more holistically our modes of dwelling in natural and built environments. From phenomenological readings of actual places to interpretations of artistic and literary accounts, to thoughtful, first-hand observation of particular settings, the primordial concern is to illumine taken-for-granted paradigms that condition environmental perceptions and interpretations of place (Stefanovic, 2000).

At times, the way of phenomenology can be frustrating, to the extent that methods challenge traditional attitudes and require a new way of seeing and of asking questions. Nevertheless, properly employed, the methods are rigorous and high standards of qualitative research are demanded. Whether engaged in a phenomenological reading of place or in-depth interviews, the task is to illumine taken-for-granted attitudes and investigate the ontological grounds of judgments that, in every case, inevitably frame the process of environmental decision-making by scientists, public policy makers and laypersons. It is for this reason that phenomenology is described by some philosophers as nothing less than foundational ecology.

Environmental Psychology/Perception

Charles Vlek

University of Groningen, Groningen, The Netherlands

Global environmental problems have socio-behavioral causes for which technology offers only one (partial) solution strategy. Focusing on fundamental mechanisms of environmental degradation, this entry is about models and methods for social behavior change to reduce collective environmental risks. The exposition develops around an analysis of societal driving forces, economic system characteristics, and individual determinants human needs, opportunities and abilities underlying stressful behavior patterns. The common-resource (or: commons) dilemma paradigm is utilized as a general model for understanding and managing con icts between (short-term) individual and (long-term) collective interests. Following this model, any collective environmental problem and its behavioral causes first need to be diagnosed. Secondly, an evaluation and weighting of individual benefits versus collective risks is required. And thirdly, well-tuned policy interventions must be consistently planned, executed and evaluated. Various behavioral science ingredients are introduced for a sources and causes analysis of collective environmental problems and for specifying effective ways to limit environmental risks within sustainable levels.

Particular attention is devoted to human needs and values, and the relative importance of material wealth for people s overall quality of life. It is hoped that, hereby, physical and economic scientists as well as policy makers may be

inspired to conduct more fundamental problem analyses and to design more effective policies than is customarily done.

MACRO-LEVEL DRIVING FORCES OF UNSUSTAINABILITY

More than 20 years ago Ehrlich and Holdren (1971) introduced a simple formula to estimate the total environmental impact of a particular society, country or region. The present popular version of this equation is: $I = P \times A \times T$, or: environmental impact (I) equals the product of population size (P), the degree of affluence (A) per person, and the quality of the technology (T) used to produce one unit of affluence. The formula implies that there are three different fronts at which the battle for sustainable development is to be fought, viz. population, affluence (production and consumption) and technology. The formula also reveals the substitutability of one component by another. To illustrate, total environmental impact might remain constant under considerable population growth, as long as average personal affluence and/or the resourcefulness per unit of affluence is/are proportionally reduced. Also, while total environmental impact stays constant, the degree of affluence per person may well increase significantly, provided that the number of people and/or the resourcefulness per unit affluence is/are proportionally reduced.

Under an IPAT-perspective, for example, several Organizations for Economic Co-operation and Development countries (like the Netherlands) have little reason to feel comfortable about their sustainability: their population keeps growing – partly through immigration – their affluence is increasing – they are set on economic growth, and the resource needs of their production and consumption technology is hardly decreasing. Also from an IPAT-perspective, (Winter, 1996, 23) even nominates the US for the world's most overpopulated country, not per km^2 but given its citizens' affluence and the resource demands of its technology.

The IPAT formula enables one to explain, predict and eventually manage the size and seriousness of environmental impact, for different geographic regions or countries of the world, to determine the most important impact growth factor(s) and to draw conclusions on optimal environmental management policies. Goodland *et al.* (1994) have systematically examined the potential for change in the three areas covered by the IPAT formula: (1) limiting population growth; (2) limiting affluence and consumption growth; and (3) reducing the resource needs of production and consumption technology. Like Corson (1994), these authors generally focus on a number of policy priorities, which are different in character for high-income and low-income nations of the world. For example, high-income nations are advised to work on:

- transforming the culture of consumerism ••• into an ethics of sufficiency and environmental sustainability;
- internalizing environmental costs in energy prices and accelerating the transition to renewable energy sources (Goodland *et al.*, 1994, 153).

In contrast, the authors advise low-income nations to give priority to: accelerating the transition towards population stability •••, supporting technologies which provide increased employment opportunities for unemployed and underemployed individuals •••, and improving efforts towards poverty alleviation (p. 154).

Goodland *et al.* (1994, 154) generally conclude: technological change and population stabilization cannot suffice to move the world towards an environmentally sustainable future. Instead, a reduction in per capita consumption in high-income nations and a decrease in environmental throughput are required .

In a mid-term report of a multidisciplinary project about sustainable household metabolism, Noorman and Schoot Uiterkamp (1998, 252) conclude:

> the challenges posed by climate change and the desire for equity ••• are formidable. It is clear that to achieve the reduction goals indicated above will require major changes in the metabolism of households and of production. Specific redesign rather than evolutionary change is essential, although this may appear to be at odds with the actual trend of ever-growing development, production, consumption, and disposal of products and services. This is especially true in areas where the fastest growth in consumption is in high energy intensive items (such as cars).

If we search for the socio-behavioral causes of population growth, increasing affluence and an ever more resource-hungry technology, we hit upon other driving forces of unsustainable development, viz. institutions as vehicles for governing human societies, and culture as the conglomerate of socially shared beliefs, values and attitudes. Embedding and shaping the latter two forces are historical developments such as industrialization, division of labor, urbanization and market competition; see Røpke (1999) who indicates two fundamental pre-conditions for the historical generation of wealth in the North, viz. the availability of cheap fossil fuels and the immense transfer of resources from the South to the North (Martinez-Alier, 1995). This is in line with Dietz and Rosa's (1997) argument that the technology component in the IPAT-formula encompasses much more than was originally suggested. Actually T incorporates cultural, social, technical and infrastructural factors, which together determine how much environmental impact an activity is producing. Adding culture and institutions to the IPAT-formula might yield a CIPAT-equation. After rewording just two factors we obtain TEDIC, to indicate a complex of technological, economic, demographic, institutional and cultural developments in industrial society, which did and do stimulate societal (global, or regional) unsustainability. In Dutch, te dik, pronounced similarly as TEDIC,

means too big or too fat. In a different wording and order, the five driving forces have also been distinguished by Stern (1992); see also Vlek (2000).

The several driving forces of unsustainable development are schematized and clarified in Figure 1, which also indicates that (un)sustainability involves economic security and social well-being as well as environmental quality. What Dietz and Rosa (1997) noted about technology (see previous paragraph) may be similarly argued about population as well as affluence: *P* and *A*, too, incorporate cultural, social, technical, infrastructural and other factors driving their (geographically different) growth, particularly during the last 50 years. For population, Hilderink (2000) has computer-simulated the effects of various relevant factors such as fertility, diseases, birth-control and health policies, environmental conditions and economic growth. His conclusions are that in most regions population growth will come to a standstill, that world population in 2055 will stay below 9 billion after which it will decrease to 7.6 billion in 2100, and that United Nations population projections tend to be exaggerated. For affluence, to be further discussed herein, basic behavior determinants are people's needs, opportunities and abilities (NOA) to produce and/or consume, as also indicated in Figure 1.

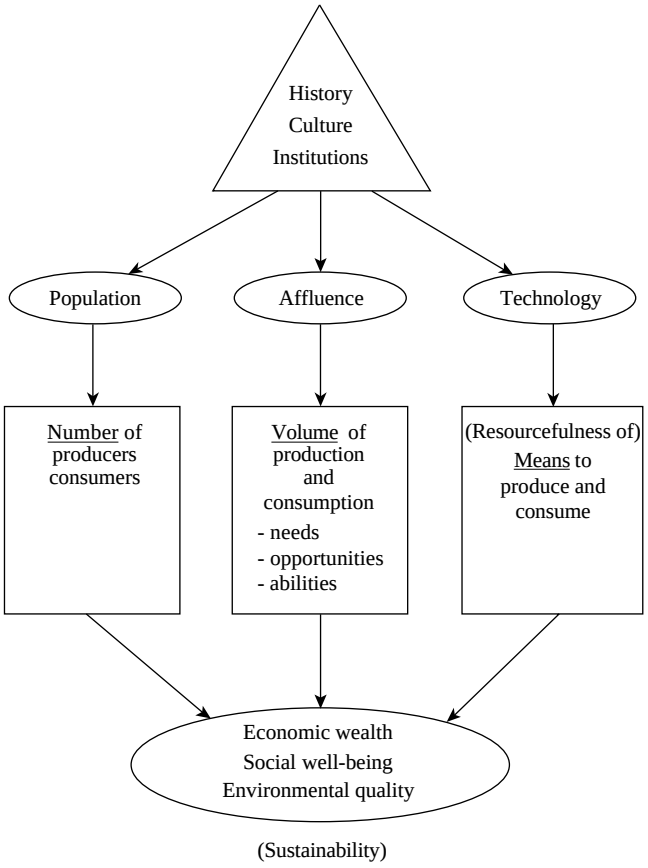

Figure 1 Schematic representation of driving factors underlying economic, social and environmental sustainability dimensions, as embedded in history, culture and institutions

In terms of Figure 1 one may conclude that the battle for sustainable development pertains not only – directly – to population, affluence (production/consumption) and technology, but also – indirectly – to institutions and culture. Thus, on the basis of an intense series of experts' and stakeholders' meetings, Vellinga *et al.* (1995) distinguish five strategic policy options for reducing the societal risks of climate change. These are, respectively:

1. *no regrets*: the climate problem is too uncertain, priorities will be given to policy instruments serving other (socio-economic and environmental) objectives;
2. *least regrets*: a serious climate risk problem is acknowledged, but policies will be aimed at a balancing of the risks of intervention and non-intervention;
3. *acceleration*: climate change is addressed along with other, shorter-term environmental problems, making use of synergies and positive feedbacks in society;
4. *technological innovation*: technology is the only way to meet growing demands and provide environmental security;
5. *institutional and cultural change*: technology being insufficient, major cultural and institutional changes are required to create a sustainable society.

Somewhat to their surprise, the authors noted that among project participants there was less agreement about the five strategic policy options above than about various fields of action that might be addressed (more or less strongly) under all five directions, e.g., introduction of ecotaxes, a low-carbon transport system, renewable energy sources, and the stimulation of technological and cultural innovations.

MESO-LEVEL PRODUCTION–CONSUMPTION CYCLES

The driving forces represented in Figure 1 are characteristic of a complex socio-economic system in which capital, labor and environmental resources are being used for the production of goods and services to meet the needs and desires of numerous consuming individuals, groups and organizations. To understand this complex metabolism of society vis à vis the natural environment, it is necessary to appreciate the interwovenness of household consumption and industrial production. Figure 2 represents what may be called the production-consumption cycle, as institutionalized in a social, i.e., government-regulated market economy. A more elaborate version of Figure 2, also containing an inner consumer self-production cycle, is presented in Vlek *et al.* (2000).

Figure 2 reflects the simple truth that consumers and producers need each other for different reasons, and

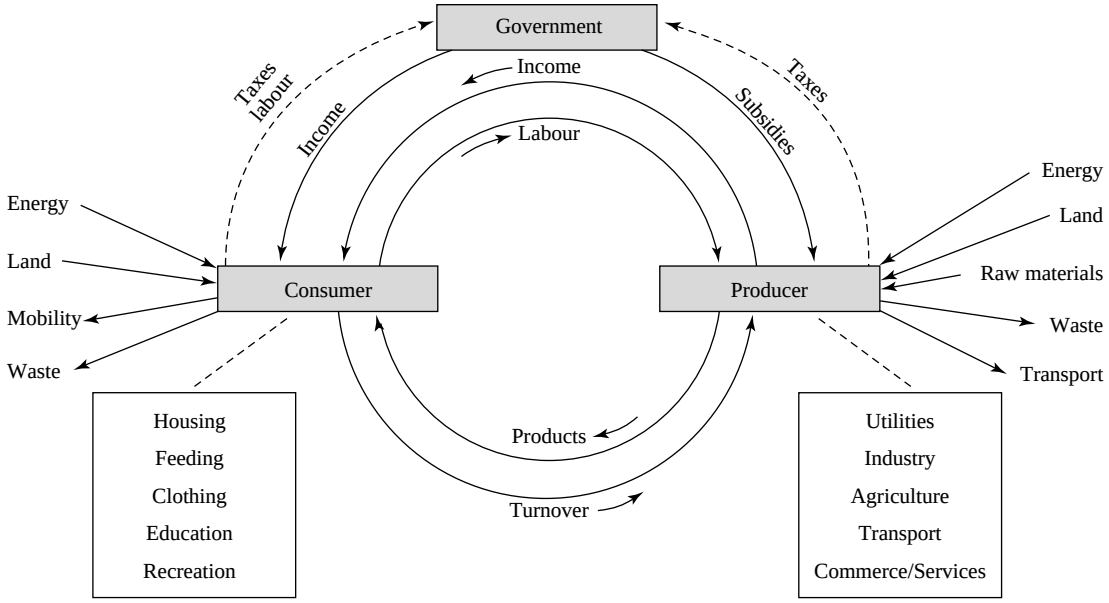

Figure 2 Model of the production-consumption cycle in a government-regulated market economy

that both parties need some government regulation, for which government in turn needs consumers and producers, again for different reasons. The relationships among the three groups are expressed in flows of money, products, labor, taxes and subsidies. The main system functions for consumers are feeding, clothing, housing, education and recreation. The major functions for producers are energy provision, industrial production, agriculture and stock-breeding, product distribution and services. Inputs from outside the socio-economic system come from various environmental resources such as energy, raw materials and land area. External outputs or derivatives occur in the form of various kinds of waste, mobility and noise.

A second observation about Figure 2 is that the whole (Western) production-consumption system is steadily accelerating. This is because it operates under the economic goal of ef ciency, because ef ciency breeds ef ciency and because most people involved cherish ef ciency for reasons of social comparison, competition and status. If ef ciency were less dominant and if material wealth were de-emphasized as one quality of life variable (see further herein), social market economies could decelerate as well as dematerialize (*see* **Dematerialization and Sustainable Development**, Volume 4), to the bene t of other important qualities of life, including social justice, environmental security and natural biodiversity.

Figure 2 can also illustrate a third, not so obvious point. This is the mutual interdependence of producers eco-ef ciency and consumers suf ciency. Eco-ef ciency is the producer s strategy of reducing the overall resourcefulness per unit of production goods or services (*see* **Eco-ef ciency**, Volume 4). However, the bene cial effects of eco-ef ciency may be undone by (further) consumption growth and rebound (or take-back) effects. Hence, eco-ef ciency on the producer s side needs a counterpart on the consumer s side. The latter must necessarily be a strategy of suf cient consumption or suf ciency (Durning, 1992, Chapter 10; Goodland *et al.*, 1994; Reisch and Scherhorn, 1999). This stands in contrast to the current (highly-industrialized) norm of ever-growing, continually maximizing consumption patterns (never enough, says homo oeconomicus).

MICRO-LEVEL DETERMINANTS OF RESOURCEFUL BEHAVIORS

For understanding individual producer and consumer behaviors, and as a prelude to the planning of needed social behavior change, some well-established theories and models of human behavior must now be considered.

Following the NOA-model as presented in Figure 3 (translated from Vlek *et al.*, 1997; inspired by Olander and Thøgerson, 1995), individual consumer behavior is considered as dependent upon the needs (Ns), the opportunities (Os) and the abilities (As) to undertake a particular activity. Needs and opportunities interact to shape people s motivation to perform an activity, while opportunities and abilities together determine subjects behavioral control. Hence, changing resourceful consumer behavior (or producer behavior, for that matter) would involve changing people s (or organizations) needs, their physical, technical or social opportunities and/or their physical, mental or nancial ability or capacity to engage in the relevant behavior. The NOA-model may be linked to the model of

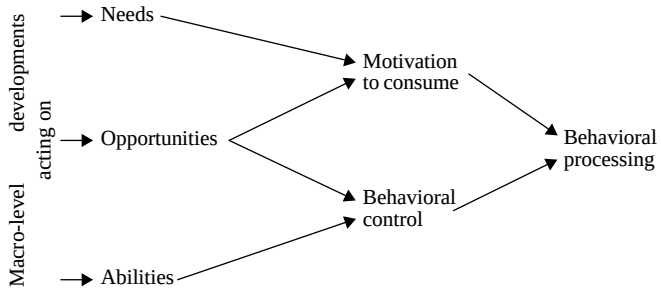

Figure 3 The NOA model of individual consumer behavior. The 'implicit and explicit forces'. ••• at the left are taken to be cultural, institutional, economic and other types of influential societal developments

the social market economy as represented in Figure 2, in order to identify the various actors and factors underlying any party's NOA to undertake resourceful behaviors.

Geller (1989) has proposed an integration of applied behavior analysis (ABA) – involving immediate rewards or punishments, following instrumental and social learning theory (see Geller *et al.*, 1982) – and a pragmatic social marketing approach (Kotler and Zaltman, 1971). Geller's (1989) four-stage ABA-marketing model sequentially comprises: (1) market analysis; (2) market segmentation and selection of target behaviors; (3) design of market strategy and ABA; and (4) evaluation via self-reports and behavior observations. Documentation and dissemination of results plays a key role in the model's practical application.

Stern *et al.* (1999) have proposed and tested a value–belief–norm (VBN) theory for understanding environmentalism in people's actions and behaviors. Their VBN theory links conceptions of moral norms, personal values and environmental attitudes into a coherent set of practical measurements. Their empirical study was aimed at explaining people's degree of environmental citizenship, their private-sphere behaviors, and their willingness to sacrifice for the support of government policies. Stern *et al.*'s study revealed that VBN theory is a far better predictor of environmental behavior indicators than other, less coherent conceptions of people's environmental motivation. This demonstrates that social and personal norms and values play crucial roles in changing behaviors.

The three models just discussed may each be considered as a general matrix for approaching human behavior change. Their consistent message is that effective policies should be aimed at changing fundamental determinants of unsustainable behaviors. In working with such models it is useful to distinguish four basically different types of behaviors. These may be categorized following two major dimensions under which specific behavior determinants can be specified. The first dimension ranges from deliberately planned or reasoned behavior on the one hand, to automatic behavior involving well-established habits, on the other. The second dimension ranges from private to public behavior determinants. The resulting two by two scheme is depicted in Table 1, whose quadrants may be conveniently labeled as deliberation, social comparison, repetition and imitation, respectively. For each behavior type two relevant, well-established behavior theories are indicated.

This simple psychological taxonomy may help us find an appropriate behavior theory or model and methods to understand and possibly influence environmentally impactful behaviors. The message here is that the four behavior types should each be addressed in a specific well-tuned way, in order for behavior change to come about. For example, repetitive (habitual) behaviors may best be approached via changes in a person's physical–technical environment. In contrast, deliberation may be influenced via argumentative information about optimal choices. Likewise, imitative behaviors may best be changed via social example setting and the pressure of social norms. Alternatively, social comparison is rather sensitive to argumentative information about other people's behavior. Disregarding the behavioral distinctions in Table 1 may yield perhaps well intended (and costly), but possibly ineffective policy strategies.

Exploiting the taxonomy of Table 1, Jager *et al.* (2000) have computer-simulated consumer behaviors to clarify which individual and social behavior mechanisms would lead to a earlier or later depletion of a common resource. In several simulation experiments contrasting *Homo psychologicus* and *Homo oeconomicus*, Jager *et al.* demonstrated that resource depletion was accelerated by an optimism effect, an imitation effect and an adaptation effect, which all flourished under uncertainty about the current size of the common resource.

SHORT-SIGHTEDNESS: COGNITIVE LIMITATIONS AND BIASES

Whatever behavior theory applies, there always is the human condition of psychological limitation, which makes environmental risk management rather difficult. Modern societies are confronted by huge discrepancies between the complexity, the uncertainty and the temporal extension of major environmental costs on the one hand, and the relative simplicity, certainty and immediacy of social and economic benefits on the other. By their very nature, the short-term, concentrated benefits are cognitively more available and can be better appreciated than the long-term, widespread costs. Bjorkman (1984) uses the term proximal cognition to explain this unevenness, which tends to make large parts of modern society to be the prisoner of an us, here and now' trap (Vlek and Keren, 1992). This precludes prudent long-term planning and decision making about developments involving major environmental impacts. Historically, such a psychological imprisonment is fairly unique, since earlier societies did not (yet) have the knowledge and the technical means for such large-scale

Table 1 Four different behavior types in two dimensions (translated from Vlek *et al.*, 1997)

	Private determination	Public determination
	Deliberation:	Social comparison:
Reasoned behavior	Decision and choice theory[a] Theory of planned behavior[b]	Social comparison theory[c] Relative deprivation theory[d]
	Repetition:	Imitation:
Automatic behavior	Classical conditioning theory[e] Instrumental learning theory[f]	Social learning theory[g] Theory of normative conduct[h]

The theory of planned behavior[b] (Ajzen, 1991) also incorporates a social component, the subjective (social) norm; hence it partly fits also under public determination. References for the other seven theories are: [a]Hogarth (1987), [c•d]Masters and Smith (1987), [e]Pavlov (1927), [f]Skinner (1953), [g]Bandura (1977), and [h]Cialdini *et al.* (1991).

and multidimensional environmental exploitation as has occurred particularly during the past 50 years.

Pawlik (1991) has indicated five fundamental reasons for most people's lack of appreciation of large-scale environmental risks such as global climate change. First, the signals of climate change, as exemplified by atmospheric temperature changes, are relatively weak compared to the background noise of normal temperature variations. Second, cause–effect gradients of global environmental change are strongly masked and extended in time; it is very difficult to tell which effects are the (indirect, long-term) result of which causes. Third, low-probability (extreme weather) events tend to be seen as impossible and their occurrence as accidental; this hinders the design of effective risk management strategies. Fourth, there is a large social distance separating actors and victims of global environmental change; this naturally suppresses actors' feelings of responsibility. Fifth, there is a low perceived cost-effectiveness of conservation behavior; often wasteful behavior is more profitable here and now. In an international review of studies about human responses to environmental stress, Jager and Vlek (1993) conclude that people are inclined to deny and remain passive about those kinds of environmental nuisance and risk that they believe to be uncontrollable.

In a critical psycho–cultural analysis Gladwin *et al.* (1997) wonder: why is the northern elite mind biased against community, the environment and a sustainable future? These authors identify four principal and interrelated origins (pp. 238–240): (1) a cognitively bounded biological mind; (2) an obsolete worldview mind; (3) an addicted contemporary mind; and (4) a delusional psychodynamic mind. They then formulate four sets of hypotheses about the different minds and provide a research agenda for investigating the conditions for developing a sustainable mind. For example, hypothesis two (p. 241) reads: the biomind is adapted for proximity rather than distance . Hypothesis 10 (p. 248): the viewmind conceives reality according to individualism rather than communitarianism . Hypothesis 11 (p. 250): the contempmind is programmed to favor market efficiency rather than social justice . Their hypothesis 19 reads: the psychomind protects the self from anxiety via rationalisation rather than accurateness .

COMMONS' DILEMMAS IN PRODUCTION–CONSUMPTION ACTIVITIES

The cognitive–motivational factors and tendencies just described are at the basis of what nowadays is known as the common-resource (or commons) dilemma (Hardin, 1968; Platt, 1973; Dawes, 1980; Vlek, 1996). In such social situations a collective (environmental) cost or risk is incurred or generated via the combined negative externalities of numerous individual benefit-seekers who act independently from one another. Vivid examples are the exploitation of fishing grounds by various companies, metropolitan air pollution through massive use of motor vehicles, and large-scale damage to natural ecosystems by expanding road infrastructure. Note that societal meso-level processes in production–consumption cycles (cf. Figure 2) operate as revolving doors for collective risk generation and management, as they are rooted in often powerful organizations of resourceful activities.

In our times, the classical conflict between individual and collective rationalities has acquired frightening proportions. Regarding highly industrialized society the Belgian philosopher Vermeersch (1988, 29) dramatically formulates this conflict as follows (translated from the Dutch):

> the whole forms a system which rushes on autonomously, and nobody can guarantee that somewhere at the end of the route there is a goal waiting which is still meaningful for people. ••• The aimlessness, the irrationality of the total system is being obfuscated by the utter rationality of the system's separate components.

The situation Vermeersch refers to represents a class of market failures that Kahn (1966) has called the tyranny of small decisions. The environmental and social consequences of such social traps (Platt, 1973) are also discussed by Hirsch (1976).

The examples above also indicate that many commons dilemmas have a layered structure comprising various contributing actors and risk managers, who may be identified at the micro-, meso- and macro-levels of society. Individuals may be embedded in groups, which are embedded in organizations, which are embedded in countries. This may go up to the international level where diplomats are facing complicated dilemmas concerning, e.g., the abatement of global atmospheric warming. Due to their layered structure, such commons dilemmas are hard to manage, since there is ample room for external cost-shifting behaviors as well as great difficulty to reach workable control agreements.

For social policy makers, a common-resource dilemma – if recognized as such – constitutes a permanent (dynamic) contrast between a collective risk and an often large collection of individual benefits; minimization of the risk and maximization of the benefits are incompatible social goals between which a trade-off is to be made. Thus, the solution of any commons dilemma consists of a sustainable balance between numerous individuals' (and/or groups', organizations', countries') benefits and the collective costs and risks for all.

What happens in a commons dilemma usually exceeds the physical, cognitive and motivational scope of individual actors. Therefore, the basic question is how the collective cost or risk can be validly assessed, effectively evaluated and acceptably managed so as to stay within sustainable limits (not easy to assess in advance). Collective risk management is a matter of decision-making about risk acceptance and the selection of practical strategies for risk control via social behavior change. Such risk management may be most effective if it links up with the problem diagnosis concerning the behavioral processes whereby the risk is being generated or enhanced. Each major risk management step may be unfolded into three different policy tasks. Thus, understanding commons dilemmas and managing collective risks revolves around nine distinct policy tasks, as listed in Table 2.

Table 2 Nine policy tasks for managing common-resource dilemmas (after Vlek, 1996)

I. Problem diagnosis
1. Analysis and assessment of the collective-risk and risk generation process
2. Promoting social risk perception and communication
3. Analysis and assessment of (numerous) individual benefits
II. Decision making
4. Weighing of collective risk against total individual benefits (need for change?)
5. If risk unacceptable: specification of safer behavior alternatives
6. Setting risk reduction objectives and translation into behavior goals
III. Risk control
7. Design and selection of policy instruments for behavior change
8. Programmatic application of various strategies for behavior change
9. Monitoring, evaluation and feedback of effects of risk reduction policies

The three divisions of Table 2 indicate the key problems in understanding and managing collective risks in commons dilemma situations: raising awareness and appreciation of the collective risk, weighing the risk against (total) individual bene ts, and promoting social behavior change (or restraint). This partly overlaps with three well-known keys to resolving social dilemmas (Dawes, 1980) knowledge, morality and trust. In a thorough analysis of commons dilemma problems Edney (1980) emphasized territorialization (or regionalization, to increase users responsibility) and trust (to reduce competition) as essential solution strategies.

STRATEGIES FOR SUSTAINABLE BEHAVIOR CHANGE

Commons dilemmas re ect persistent con icts between many individual (producer and consumer) interests on the one hand, and a small number of (large-scale) collective interests on the other. As dilemmas, they may be resolved only by the achievement of a safer, sustainable balance of individual and collective bene ts and risks. The nature and the effectiveness of various solution approaches have been investigated in a great number of laboratory and some eld experiments (e.g., Dawes, 1980; Messick and Brewer, 1983). Most of these approaches may be categorized under seven general strategies for social behavior change (Vlek, 1996; see also Cook and Berrenberg, 1981; De Young, 1993; Gardner and Stern, 1996, Chapter 7), as given in Table 3 along with exemplary speci cations.

Strategies 1 (PhAA) and 3 (FES), and certain (physical) forms of strategy 6 (OCh) would initiate so-called structural (or: hard) solutions to a commons dilemma, whose basic nature or type would thereby be altered. Strategies 2 (RaE), 4 (IEC), 5 (SMS), certain other (mental) forms of strategy 6 (OCh), and strategy 7 (CVM) would imply cognitive-motivational (or: soft) solutions (Wilke, 1989). Through the latter, individual actors would be induced to behave in a cooperative (i.e., collectively rational) manner, while the basic nature and payoff structure of the commons dilemma would be maintained. Structural solution strategies are generally more effective, but they are often not available or not easily implemented. Speci c cognitive motivational solution-strategies (RaE, IEC, SMS and some OCh) are more easy to design and apply, but their effectiveness is generally lower; in many cases, however, they are the only thing one can rely on. CVM stands relatively by itself as

Table 3 Strategies for collective risk management in commons dilemmas (Vlek, 1996)

1. Provision of physical alternatives, (re)arrangements (PhAA)	Adding/deleting/changing behavior options, enhancing efficacy
2. Regulation and enforcement (RaE)	Enacting laws, rules; setting/enforcing standards, norms
3. Financial–economic stimulation (FES)	Rewards/fines, taxes, subsidies, posting bonds
4. Provision of information, education, communication (IEC)	About risk generation, types and levels of risk, others' perceptions and intentions, risk reduction strategies
5. Social modeling and support (SMS)	Demonstrating cooperative behavior, others' efficacy
6. Organizational change (OCh)	Resource privatization, sanctioning system, leadership institution, organization for self-regulation
7. Changing values and morality (CVM)	Appeal to conscience, enhancing 'altruism' towards others and future generations, reducing 'here and now' selfishness
By default: 8. Wait and See (WaS):	Do nothing, the quay will turn the ship

a cultural solution (cf. Section 2) on which much behavior change might come to rest.

The (first) seven strategies listed in Table 3 may be applied in different variants and they may be directed at different target behaviors. Because each strategy has its own strengths and weaknesses – which may be summarily expressed in its behavioral elasticity (a dose–effect relationship) – it is generally wise to apply well worked-out combinations of strategies. Obviously, any strategy for social behavior change should be carefully tuned towards the intended target individual, group or organization. The latter should be studied to some extent beforehand, so as to obtain basic information necessary to design an effective approach.

One solution by default to a collective environmental risk problem is nicely expressed in a Dutch saying translated as the quay will turn the ship. That is, number eight in Table 3: WaS will automatically elicit behavioral (catastrophe) responses from causal agents, but these behavior changes then cannot be but inappropriate, too little and too late. Making such unsustainability scenarios palpable – e.g., via scenario studies – would mean that individual actors are (better) enabled to live under the shadow of the (common) future and duly undertake preventive action. Disaster scenarios may thus initiate self-destroying prophecies, as society tries to steer away from them.

The barriers to sustainable behavior change are manifold. In fact, like solutions, barriers may also be listed under the (first) seven rubrics of Table 3. Some examples are: absence of physical or technical alternatives (PhAA), insufficient and/or ineffective law enforcement (RaE), inconsistency of financial incentive systems (FES), unawareness of one's own causal role and possible contribution to solutions (IEC), absence or invisibility of model behaviors by opinion leaders (SMS), organizational goals biased towards short-term survival (OCh), and importance of social status in spending capacity (CVM). Specific variants of the seven strategies may be used to overcome such difficulties.

TRADABLE EXPLOITATION RIGHTS

One special combination of strategies RaE (as government regulation), FES (as payment according to use), IEC (as information provision) and OCh (as privatization) may prove to be an effective as well as efficient approach towards managing common goods. This is the management system known as tradable emission permits, more generally to be labeled as tradable exploitation rights (*see* **Tradable Permits for Greenhouse Gases**, Volume 4; **Tradable Permits for Limiting Stratospheric Ozone Depletion**, Volume 4; **Tradable Permits for Sulfur Emission Reductions**, Volume 4; **Transferable Fisheries Quotas (TFQs)**, Volume 4).

The idea here is that, for the collective as a whole, some central authority determines the maximum sustainable exploitation of some social or environmental resource (to be consumed, enjoyed or polluted), and then distributes (equally, shall we say) among its constituents a collection of tickets each representing a fixed limited exploitation right. Tickets are tradable, so that they may be purchased by those who need a greater than average resource use, from those whose demand is less than average. Ticket prices are established under free-market laws of demand and supply, but the total resource exploitation, corresponding to the ownership of a certain number of tickets, may not be exceeded. If necessary, the central authority may reduce the extent of exploitation per ticket. Alternatively, it may allow for increased exploitation, if the total resource regenerates more quickly than was originally estimated. See Koutstaal and Nentjes (1995) for an economic and legal analysis of the possibilities and limitations of tradable emission permits. The system contains several elements of the alternative commons dilemma games as discussed by Ostrom (1990, Chapter 1).

Tradable exploitation rights as a political–economic risk management system raises a number of fundamental questions. These are mainly concerned with the assessment

of the maximum tolerable overall exploitation of a given resource, the initial distribution (or perhaps: auctioning out) of exploitation tickets, and the central authority's monitoring and control over actual resource exploitation and possible violations of individual purchased rights. Effective functioning of such a system obviously requires collective rules and a sanctioning system. It also necessitates efficient operation of demand and supply pricing mechanisms. It also demands adequate provision of information and communication about exploitation rights, their availability and the monitoring and control of their actual utilization.

If appropriately implemented, tradable exploitation rights would prohibit free riding, whilst the unfairness of a fixed exploitation charge to both small and large exploiters would be avoided (see the discussion of demand revelation by Yamagishi, 1995, 313). How tradable exploitation rights as a system actually works under variations in certain basic characteristics, is a matter of controlled experimentation and creative field study. Practical examples are the distribution of tradable quota-rights for sea-fishing, dairy milk production and animal manure production, respectively, in the countries of the European Union. A promising application would involve transportation kilometers, to limit total environmental impacts from motorized transport.

In view of the common-resource dilemma model of collective environmental problems, tradable exploitation rights is an almost ideal risk management system, because it is aimed at the necessary balance between individual and collective interests, between government and market and (thus) between individual freedom and social equality.

A related risk management system, also involving a combination of various Table 3 strategies, is bond pledging or hostage posting for ensuring collectively responsible behavior. The basic idea is that individual actors promise to be cooperative, and that they commit themselves by pledging a bond (which serves as a hostage). The bond – or hostage – is lost when they defect and behave against the collective interest. Raub and Keren (1993) and Keren and Raub (1993) discuss the theoretical nature and implications of such a system, and they offer empirical evidence for its effectiveness. An interesting practical example from environmental policy is couched in a Swiss proposal to drastically increase fuel prices for motorcars, and then at the end of each year pay a bonus out of a national fuel fund to those who would prove to have driven less than a certain number of car-kilometers (VCS, 1990).

CONDITIONS FOR SOCIAL BEHAVIOR CHANGE

Global environmental problems offer good reasons for social behavior change. Common-resource dilemmas confront subjects with necessary risk–benefit trade-offs and the prompting of direction of needed change. The risk management strategies and systems discussed above can be instrumental in bringing about social change. From such policy foundations as well as from various empirical research (e.g., De Young, 1993; Oskamp, 1995; Gardner and Stern, 1996; Steg and Vlek, 1997) we may distill the following essential conditions for social behavior change, considered from the subject's point of view; see Table 4.

Fulfilling these conditions is like answering obvious questions by subjects of policy intervention campaigns, such as: what is the problem? What is my own responsibility? What (else) could I actually do? Will others cooperate as well? Can we trust risk experts and managers? Where would this all lead to? The latter question in particular is rarely addressed in environmental policy debates. Sustainable futures have much to do with meeting basic human needs and values (cf. WCED, 1987), to be discussed herein, in the section on human needs and values.

HUMAN NEEDS AND VALUES

Individuals, groups and organizations consume raw materials, energy, products and services because they are driven by basic needs and wants, because they cherish cultural beliefs and values, and because they are guided by social and economic institutions. Together, need satisfactions and value manifestations make up people's quality of life. The latter is a multidimensional concept comprising variables such as health, family relations, work, income, housing accommodation, safety and environmental quality (see, e.g., Ormel *et al.*, 1997; Gatersleben and Vlek, 1998; Diener, 2000). Quality of life is not necessarily affected by additional commodities that consumers are urged to desire through clever advertising. The reason is that material goods can be associated with the promise to fulfill needs they are not suited to fulfill.

Human needs and values are numerous and have been the subject of various taxonomies (McDougall, 1932; Maslow, 1954; Max-Neef, 1992; Schwarz and Bilsky,

Table 4 Essential subject-conditions for social behavior change

1. Sufficient awareness of and insight into the collective environmental problem
2. Appreciation of one's own contribution to the problem and one's co-responsibility for solutions
3. Visibility and consistency of strategic policy goals
4. Availability of feasible behavior alternatives
5. Personal (extrinsic and/or intrinsic) incentives for behavior change
6. Basic trust in cooperation of fellow subjects
7. Basic trust in relevant management agencies and authorities
8. An acceptable image of the future resulting from social behavior change

1987). Maslow's well-known needs hierarchy relates physiological, safety, belongingness, esteem and self-actualization needs. Maslow holds that the lower needs are more elemental, and hence override the higher needs in case of deprivation.

Max-Neef (1992) has proposed a taxonomy of nine human needs, which successively involves subsistence, protection, affection, understanding, participation, leisure, creation, identity and freedom. The author separates these general needs from the various specific ways in which they may be satisfied. Four existential categories of needs satisfaction are distinguished: being, having, doing and interacting, respectively. For example, a person's need for identity may be satisfied by being outspoken, having a German shepherd dog, regularly doing hard work, and interacting (meeting) with friends in the local cafe.

Being, having, doing and interacting to satisfy certain needs or to manifest certain values often involve raw materials, energy, products and services. A general question, therefore, is: to what extent may valid (general) human needs be fulfilled in a far less energy- and material-intensive way so as to better fit into society's sustainable development? Another question is: to what extent and in what way might resourceful need-satisfying states (being), possessions (having), actions (doing) or interactions be reinterpreted such that they are going to be seen as actually far less need-satisfying than they originally were considered to be? The latter question touches upon the possible illusory nature of culturally normal and socially accepted ways of needs satisfaction, and it would entail a discussion about more authentic and meaningful ways of satisfying our real needs.

After surveying various theories and taxonomies of human needs and values, Vlek *et al.* (1998) used a shortlist of 22 different quality of life variables to explain people's feelings and judgments about prospective changes in their country's environmental and economic conditions. It appeared that (Dutch) questionnaire respondents expected more positive changes from environmental quality improvement along with economic recession, than from (further) environmental deterioration along with continued economic growth. In a household scenario evaluation study, Poortinga *et al.* (2000) requested 450 respondents to rate each of the 22 variables for its importance to their overall quality of life. After factor analysis it appeared that, with one exception (social justice), the 22 variables could be compactly summarized into seven factors, together explaining 60% of the variance in people's importance judgments. These factors, together with the variables that they include, are given in Table 5, in top–bottom order of averaged importance. Note that maturity, openness to change and material wealth were judged to be less important than family, health and safety, personal freedom and achievement.

Jackson and Marks (1999) scrutinize the question: to what extent does economic growth actually deliver increasing welfare, as is being supposed in neo-classical economics? They refer to Max-Neef's (1995) threshold hypothesis which holds that, in Western-industrial growth patterns, the many economic goods are increasingly being counterbalanced by three basic economic bads, viz. depletion of natural resources, degradation of the natural environment, and various costs to the quality of human life. After considering various data on increased consumer spending on material as well as nonmaterial needs (such as leisure), Jackson and Marks (1999, p. 439) appear to find it difficult to infer increased needs satisfaction from increased expenditure. They also state that material consumption might well provide pseudo-satisfaction of nonmaterial needs or even inhibit or violate those needs.

Ever since Adam Smith (1776), economists have argued that human welfare depends on material wealth, and even today they neglect the contrary experience suggesting that their assumption is valid only when people live in material scarcity. In an affluent society, welfare loses its correlation with wealth.

> The reason why economic growth no longer brings a sense of greater well-being, why the pleasures our new possessions bring melt into thin air, is that at the level of affluence of the American middle class what really matters is not one's material possessions but one's psychological economy, one's richness of human relations and freedom from the conflicts and constrictions that prevent us from enjoying what we have.

In debates about quality of life dimensions such as health, family relations, work and leisure time we often underestimate the fundamental human need for variety and change (not so important following Table 5): we generally don't want to be, have, do and interact with the same (person, goods, jobs or other people, respectively) every day or week of the year. Most people (want to) vary

Table 5 Seven quality-of-life (QoL) factors summarizing 21 out of 22 specific QoL-variables (given in brackets)[a]

6.	Family health and safety (health, partner and family safety)
3.	Personal freedom (freedom, privacy, leisure time)
7.	Achievement (education, work)
2.	Environmental quality (environmental quality, nature/biodiversity, aesthetic beauty)
5.	Maturity (identity/self-respect, security, spirituality/religion)
4.	Openness-to-change (social relations, change/variation, challenge/excitement)
1.	Material wealth (money/income, comfort, status/recognition, material beauty)

[a] From top to bottom factors bundle from (roughly) more to less important QoL variables. Factor numbers indicate the order of eigenvalues, i.e., the percentage of total variance explained by that factor.

in their behaviors between: rationality and emotionality, security and challenge, stability and change, uniformity and variety, tradition and innovation, comfort and hardship, inconspicuousness and social distinction, communality and individuality, and between norm-adherence and norm-transgression. Any kind of consumption (or production) pattern sustainable or not should therefore incorporate reasonable variations along the existential polarities indicated above. If sustainable behavior would (only) be rational, secure, stable, uniform, traditional, comfortable, inconspicuous, communal and norm-adherent, it would fundamentally deter most people for literally all too human reasons. Scitovsky (1976) might summarize this by saying: such a life would provide much comfort all right, but it would not give enough pleasure .

CONCLUSIONS AND SUGGESTIONS

Environmental damage and risks local, regional and global result from a complex whole of diverse behavior patterns making up a lively society. Harmful effects, in the short and/or the long term, can only be prevented if one addresses the causal mechanisms and the sources of environmental over-exploitation. Therefore, collective environmental problems are socio-behavioral problems for which technology offers only one (partial) solution strategy. Other strategies should be focused on population, economic processes, societal institutions and cultural beliefs, norms and values (cf. Figure 1).

In several respects, global environmental problems may be too far away for us, here and now, to appreciate and care about them. The psychological trick for managing them nevertheless would be to coordinate global policy measures with more proximate regional and local policies. This can only be accomplished via causes-and-sources oriented policy approach. Taking again the example of mass motorization, policies could be aimed at reducing global carbon dioxide emissions, regional air pollution and land use, and local noise and safety problems simultaneously, if they acted comprehensively on the private motorcar system as underlying a spectrum of environmental pollutants.

In democratic countries, effective environmental policies tend to be politically controversial, if not unacceptable. This can be understood in terms of the common-resource dilemma, where individual freedom stands in permanent opposition to social equality. In their tragic choice theory, Calabresi and Bobbitt (1978) even hold that freedom and equality are incompatible social goals, whilst a democratic system by nature cannot warrant equal allocation of opportunities and wealth. However, the ideal solution nding a sustainable balance between freedom and equality requires powerful statesmanship, which may be based on the principle that individual liberties should be subordinate to collective social and environmental qualities essential for all.

Finally, global environmental policy makers are facing huge differences in sustainability pro les between different regions of the world. The United Nations Human Development Report 1998 (UNDP, 1998, 1) states: the 20th century growth in consumption, unprecedented in its scale and diversity, has been badly distributed, leaving a backlog of shortfalls and gaping inequalities .

Shortly after the appearance of *Our Common Future* (WCED, 1987), William Ruckelshaus (1989), a former director of the US Environmental Protection Agency, wrote that sustainable development should mean: (a) economic development within ecological limits; and (b) worldwide equitable economic development (Ruckelshaus, 1989). From a psychological point of view, these two international problems rest upon very similar foundations. Both global environmental degradation and widespread human poverty challenge human intelligence, international trust and worldwide morality, so that we can be aware of the problems, design creative solutions and work towards a common future of economic security, social well-being and environmental quality. If we can y around the world within 48 hours, shouldn t we be able to understand and manage the global problems that modern life entails?

Environmental Security

Steve Lonergan
University of Victoria, Victoria, Canada

With the demise of the Cold War, there has been a rethinking of our traditional perspectives on security. Numerous authors have posited that our concentration on military security may be out of date, and that factors such as disease, human rights, and environmental degradation may pose equal, or even greater, threats to national security. At the same time, there is an increasing sense that states may not be able to guarantee the security of communities and individuals, particularly in reference to these new threats. Global environmental change poses a threat not only to the natural systems on which life depends, but may pose risks to the security of individuals directly. The purpose of this article is to present these views, and provide a new way of thinking about the human dimensions of global change.

THE EVOLUTION OF ENVIRONMENT AND SECURITY RESEARCH

National security has focused traditionally on protecting the territorial integrity and political sovereignty of the state from military aggression from other states. This generally has involved forming alliances and investing in military assets in order to deter potential adversaries and use force effectively when required. In recent years, there has been increased emphasis placed on expanding the traditional conception of security to include so-called non-conventional threats such as resource scarcity, human rights abuses, outbreaks of infectious disease, and environmental degradation caused by toxic contamination, ozone depletion, global warming, water pollution, soil degradation and the loss of biodiversity (Ullman, 1983; Renner, 1989; Westing, 1989). These discussions, in turn, have stimulated research on examining the specific relationship between environment and security.

The literature on environment and security emerged in the 1970s. However, prior to this, as early as the 1950s, discussions on the issue of environmental change and security occurred without explicit use of the term environmental security (Osborn, 1953; Brown, 1954; Ophuls, 1977). Following from these discussions, in 1977, the US Central Intelligence Agency established an environmental center to assess the relationships between environment and security. The US military's use of defoliants in Southeast Asia during the Vietnam War focused international attention on both the intentional and unintentional environmental damage caused by war. The Additional Protocol I to the 1949 Geneva Convention on the Protection of Victims of International Armed Conflicts (1977) was the first of two treaties with major environmental importance that stemmed from international concern over excessive environmental degradation in Vietnam (Diederich, 1992). This primarily humanitarian agreement has to date not been ratified by a number of major powers, including the US, France and the UK, although most objections do not center on the environmental issues contained in the agreement.

Efforts to develop more stringent definitions for the prohibition of widespread, long-term and severe damage to the natural environment continued with the 1977 Convention on the Prohibition of Military or Any Other Hostile Use of Environmental Modification Techniques (the ENMOD Convention), the second of the post-Vietnam treaties.

By the early 1980s, various institutions and writers began addressing security beyond strictly military concerns that affect the state. The United Nations (UN) Commission on Disarmament and Security chaired by Olaf Palme of Sweden, made a distinction between *collective security* and *common security*. The former implied the more traditional interstate military security issues, while the latter reflected the growing array of non-military threats, including economic change, resource scarcity, population growth and environmental degradation. This was followed by the new political thinking of Russian President Mikhail Gorbachev that promoted the concept of comprehensive security as a cornerstone of international politics. Comprehensive security included various threats, including nuclear war, poverty, and global environmental issues.

Coincidentally, numerous writers addressed the issue of expanding the definition of security to include non-military threats. Richard Ullman, for example, offered the following definition of threats to security:

> A threat to national security is an action or sequence of events that; 1) threatens drastically and over a relatively brief span of time to degrade the quality of life for the inhabitants of a state, or 2) threatens significantly to narrow the range of policy choices available to the government of a state or to private, non-governmental entities (person, groups, corporations) within the state.
>
> (Ullman, 1983, 133)

While still circumscribing security within state boundaries, Ullman sought to expand the range of threats to security beyond the traditional military concerns.

The suggestion to broaden the definition of security to include environmental threats was by no means limited to American sources. Although the report of the World Commission on Environment and Development, *Our Common Future*, is best known for its definition of sustainable development, the commission also called for recognition that security was partly a function of environmental sustainability. The Commission highlighted the causal role environmental stress can play in contributing to conflict while also stating that a comprehensive approach to international and national security must transcend the traditional emphasis on military power and armed competition (World Commission on Environment and Development, 1987, 290). Westing (1989) elaborated on this statement by noting that comprehensive security has two intertwined components: political security, with its military, economic and humanitarian sub-components, and environmental security, including protecting and utilizing the environment.

The 1986 nuclear meltdown at Chernobyl and its attendant devastation for neighboring human populations and ecosystems placed health considerations squarely within a security framework for many people. The next year, President Gorbachev proposed ecological security as a top priority that *de facto* would serve as a forum for international confidence building.

The initial phase of environment and security research concluded at almost the same time as the end of the Cold War. Articles by Matthews (1989) and Myers (1989) summarised much of the debate on broadening conceptions of security. Like earlier contributions, these efforts addressed two key issues. First, there was a need to redefine security to include a new range of threats. Such threats included

population growth, resource scarcity, and environmental degradation. Second, there was an acceptance that the object of security was no longer simply the state, but ranged to levels above and below the level of the state. Myers (1993), for example, equated security with

> Human wellbeing: not only protection from harm and injury but access to water, food, shelter, health, employment, and other basic requisites that are due of every person on Earth. It is the collectivity of these citizen needs, overall safety and quality of life, that should gure prominently in the nation s view of security.
>
> (Myers, 1993, 20)

Similar to the arguments made by the World Commission on Environment and Development, Myers argues for moving from security as a freedom from various threats to security as a freedom to access environmental services.

Today, critiques of this early literature often emphasize its ahistorical and alarmist character. Some historical analyses suggest that environmental change has been a key determinant of the rise and fall of civilizations: and, ultimately, of progress in many areas of endeavor. In short, there is nothing new about this relationship. Moreover, some critics argue, the claim that human activity is hastening a catastrophe becomes less in uential as the years and decades pass. In spite of its aws, however, the early literature initiated an important debate and laid the foundations for the more rigorous research programs of the 1990s.

ENVIRONMENT AND CONFLICT

Assessing the nature of linkages between environment and security has proven dif cult. The complexity of multiple interactions and feedback poses tremendous empirical and methodological hurdles. The ambiguous and contested nature of the term *security* also complicates research and policy in the area of environment and security (Dokken and Gr ger, 1995; Lipschutz, 1995; Deudney and Matthew, 1999). As noted previously, the meanings attached to the term range from a narrow state-based de nition of safety from armed con ict, to a much broader conception of security as synonymous with human well-being. In the 1990s a number of researchers have tried to circumvent this discussion by ignoring the word *security* and concentrating speci cally on the role of environmental change and resource depletion as potential causes of violent con ict (Homer-Dixon, 1991, 1994; Libiszewski, 1992). Such con- ict, in turn, could pose a serious threat to the security of individuals, regions and nation states. The general discussions on the nature of security and the role of environmental degradation as a contributor to insecurity and con ict are labeled by Levy (1995a) as the rst wave of environment and con ict research. The empirical research that attempted to prove a link between environment and con ict has been labeled by Levy (1995b) as the second wave of environment and con ict studies.

Work at the Peace and Con icts Studies Program at the University of Toronto (Homer-Dixon, 1991, 1994; Homer-Dixon *et al.*, 1993), the Environment and Con icts Project (ENCOP) in Zurich and Bern (e.g., Libiszewski, 1992; Spillman and Bachler, 1995), and the International Peace Research Institute, Oslo (e.g., Molv r, 1991; Gleditsch, 1992; Lodgaard and Hjort af Ornas, 1992; Gr ger and Smith, 1994; Dokken and Gr ger, 1995; Hauge and Ellingsen, 1997), among others, all contributed towards this effort (see also, Durham, 1979; Westing, 1986; Gleick, 1989, 1991; National Academy of Science, 1991; Lonergan and Kavanagh, 1991). These empirical studies have been crucial, not only in terms of advancing the scholarly discussion of the links between environmental change and violent con ict, but also in publicizing the potential role environmental degradation may play as a contributor to violent con ict. Although many studies focused on the somewhat muddled concept of environmental scarcity rather than on environmental degradation *per se*, the conclusion by Homer-Dixon *et al.* (1993) was clear: ••• scarcities of renewable resources are already contributing to violent con- icts in many parts of the developing world . Subsequent work by Bachler (1998) demonstrated that environmental degradation and resource depletion may play a number of different, and sometimes subtle, roles in affecting security and contributing to con ict. These include environment as background to the tensions, as a channel leading to tension, as a trigger, as a catalyst or as a target.

Some scholars have been critical of this deterministic perspective on environment and con ict (e.g., Deudney, 1991; Dalby, 1992; Conca, 1994; Levy, 1995a,b; Hartman, 1998). Despite the range of case studies undertaken, the evidence for a direct causal link between environmental degradation and violent con ict (implied by Homer-Dixon s statement above) remains speculative and anecdotal.

CLARIFYING THE RELATIONSHIP BETWEEN ENVIRONMENTAL CHANGE AND CONFLICT

The environment and con ict literature posits that several types of environmental threats may have the capacity to contribute to insecurity and to produce con ict as well. Constraints on resources are a crucial factor that is often discussed in the literature (Choucri, 1991). Rapid industrialization and population growth in many regions have resulted in an increased demand for both renewable and non-renewable natural resources, and as Ullman (1983) and others have noted, competition for resources has historically been a major cause of con ict. This simple statement seems intuitively reasonable; however, there are some who feel it overstates the importance of resources and the environment as contributors to con ict (Lipschutz, 1995). At

first glance, the availability of water in the Middle East; the depletion of fish stocks off the east coast of Canada; and deforestation in Brazil, Thailand and elsewhere have all been, or have the potential to be, the source of conflict. It has further been suggested that atmospheric change (both global warming and stratospheric ozone depletion) has the potential to cause significant societal disruption, according to the US National Academy of Science (1991) and Myers (1993). In addition, land degradation (or land use change in general) may directly affect society's ability to provide food resources for a growing population, or may indirectly affect other changes, such as global warming. Homer-Dixon (1994) provides some evidence of these relationships and concludes that environmental scarcity (which includes environmental change, population growth, and an unequal distribution of resources) causes violent conflict. While this contention remains open to debate, it is increasingly accepted that environmental degradation is at least a contributor to conflict and insecurity.

Several other authors have attempted to clarify the possible relationships between the environment and conflict or security as well. Wallensteen (1992), for example, proposes a seven-point classification of the connection between environmental destruction and conflict and/or security.

1. Environmental destruction leading to reduced resources available to society and thus resulting in more contention in society at large.
2. Environmental destruction leading to a shift in power between already existing parties.
3. Environmental destruction leading to the formation of new parties, as part of a reaction to environmental destruction.
4. Environmental destruction leading to environmental issues becoming important for established parties.
5. Environmental destruction leading to environmental issues becoming more central in political affairs than other issues in society.
6. Environmental destruction leading to conflict behaviour involving environmentally based groups.
7. Environmental destruction leading to environmentally based conflict behaviour involving environmentally based groups.

It is clear that the environmental variable is perceived to play a number of different roles in its links to violent conflict. This is reflected in Dokken and Gr ger's (1995, 38) definition of environmental conflict as a conflict that involves environmental stress or degradation, whether as cause, consequence or intervening variable; perhaps in combination with social, ethnical or political elements . Libiszewski provides the following operative definition of an environmental conflict:

> Environmental conflicts manifest themselves as political, social, economic, ethnic, religious or territorial conflicts, or conflicts over resources or national interests, or any other type of conflict. They are traditional conflicts induced by environmental degradation. Environmental conflicts are characterised by the principal importance of degradation in one or more of the following fields: overuse of renewable resources, overstrain of the environment's sink capacity (pollution); or impoverishment of the space of living (1992 : 13).

The types of environmental issues examined as potential contributors to conflict are highly varied in terms of; (1) where they occur geographically (2) at what level they occur (local, national, regional, global) (3) the speed with which they occur and (4) the sources for their occurrence. The types of social, political and economic problems produced or exacerbated by environmental scarcity are equally diverse.

A number of researchers prefer the term *environmentally induced con ict* to *environmental con ict* to describe the environment's causal roles. Environmentally induced conflict leaves more latitude for incorporating the multiple causes that are characteristic to all conflicts. Initial evidence points to the environment as an underlying, distant, or background variable that influences or intensifies the conflict (Dokken and Gr ger, 1995). The term *environmentally induced con ict* also assists in the necessary distinction between the causes of conflict and the issues that are being fought over. Unlike conflicts over non-renewable resources or resource wars where the resources themselves are the alleged object of contention, environmentally induced conflicts often are not viewed as a unique kind of conflict. Instead environmental variables contribute to social effects that are the more traditional grievances precipitating conflict (ethnic differences, relative deprivation) (Gurr, 1993; Homer-Dixon, 1994). The environmental variables do not directly cause the conflict *per se* but instead make more salient the variables that can precipitate conflict (Libiszewski, 1992).

Many researchers do expect environmentally induced conflict from renewable resource scarcity to become increasingly frequent. Unlike non-renewable resources, technological innovation and the market have only achieved limited success in developing substitutes for renewable resources (clean air, fertile top soil) according to this line of argument. Therefore, history may not be a good indicator of future potential for conflict. Increasing environmental degradation and resource depletion, the result of increased population, higher use of natural resources *per capita*, and a constant or decreasing supply of environmental amenities, are pushing ecosystems into a highly uncertain and complex ecological future. This expectation of increasing environmental scarcity encourages many observers to predict an accompanying increase in environmentally induced conflict (Homer-Dixon, 1994; Winnefeld and Morris, 1994; Bachler and Spillmann, 1996; Kahl, 1997; Bachler, 1998).

WHAT TYPES OF ENVIRONMENTAL CHANGE AFFECT SECURITY?

The environmental forces that have been presented as contributing to insecurity are many. Environmental calamities such as earthquakes, volcanic eruptions, floods and drought have always presented a threat to human existence, and their human impact has increased considerably in scale as people have moved into disaster-prone areas. The pace of other, human-induced forms of environmental degradation and resource depletion (e.g., deforestation, desertification, land degradation, erosion, salinization, siltation, climate change), while often more gradual, has been growing rapidly in recent decades owing to a combination of increasing demand, improving technological means of exploitation, and the lagging pace of conservation and control. Meanwhile the ability and perhaps also the inclination of people to adapt to environmental stress is increasingly challenged, particularly where resources and environment provide the principal basis of their livelihood, as is the case in much of the developing world.

Types of environmental change/degradation, which may affect security, include the following:

Natural Disasters

Natural disasters include floods, volcanoes and earthquakes. They are usually characterized by a rapid onset, and their impact (destructiveness) is a function of the number of vulnerable people in the region rather than the severity of the disaster, *per se*. Poor people in developing countries are the most affected because they are the most vulnerable. (Droughts, despite a slower onset, are also included in this category.) Recent earthquakes in Pakistan, and flooding in many regions of the world indicate not only the destructiveness of disasters, but their ability to affect large numbers of people.

Cumulative Changes or Slow Onset Changes

Cumulative changes are generally natural processes, occurring at a slower rate, which interact with, and are advanced by, human activities. The processes include deforestation, land degradation, erosion, salinity, siltation, waterlogging, desertification and climate warming. Human-induced soil degradation is one factor that directly affects economic sufficiency in rural areas. Water shortages also may affect security, and Table 1 notes countries which are experiencing (or will soon experience) conditions of water scarcity, where water scarcity is generally considered to be less than $1000\,m^3$ *per capita* per year (this is a rough estimate only; many countries are able to supplement their water supply through expensive alternatives such as desalination (e.g., Kuwait) or importing water (e.g., Singapore)).

Table 1 Annual water availability, 1995 (selected countries)

Country	Annual water availability, 1995 (cubic meters per capita)
Algeria	528
Burundi	563
Egypt	923
Israel	362
Jordan	314
Kuwait	103
Libya	111
Rwanda	792
Saudi Arabia	254
Singapore	211
Tunisia	443
Yemen	359

[a] *Source:* World Resources, 1996–1997 (1996) Oxford University Press, NY.

Do factors such as water scarcity and human-induced soil degradation in and of themselves affect security? The linkage is much more indirect; in most cases, one or more of the following conditions are also present: rapid population growth, economic decline, inequitable distribution of resources, lack of institutional support and political repression.

Accidental Disruptions or Industrial Accidents

This category includes chemical manufacture and transport and nuclear reactor accidents. The two most obvious examples are the nuclear accident at Chernobyl in 1986, and the Union Carbide accident in Bhopal, India, in 1987. Between 1986 and 1992, there were over 75 major chemical accidents which killed almost 4000 people worldwide, injured another 62 000, and displaced over two million. Most of these displacements, however, were temporary.

Development Projects

Development projects such as dams and irrigation systems often involve forced resettlement and affect many aspects of human security. In India, for example, it has been estimated that over 20 million people have been uprooted by development projects in the past three decades. The Three Gorges Dam project in China, expected to displace 1 million people and the Sardar Sarovar Dam project in India are the most notable present examples. Rapid urbanization in some regions of the world is also forcing people from their land; conversion of agricultural land to urban uses has long been a phenomenon in the north, and increasingly this is the case in the South as well.

Conflict and Warfare

Environmental degradation is considered by many to be both a cause and an effect of armed conflict. Although the evidence of wars being fought over the environment is weak (except, of course, over the ownership of land), there is an increasing use of the environment as a weapon of war or, as Gleick (1990) notes, as a strategic tool. One obvious example in this category is the threat by Turkey to restrict the flow of the Euphrates to Syria and Iraq in order to pressure Syria to discontinue its support of Kurdish separatists in Turkey. Other examples include the purposeful discharge of oil into the Persian Gulf during the Gulf War and the destruction of irrigation systems during conflicts in Somalia. Such activities have similar and, indeed, more immediate consequences as do the slow onset changes noted above. But in these cases, it seems clear that the environment is merely a symptom of a larger conflict, and the root cause of any insecurity is the conflict itself, and the reasons behind it.

CRITICAL PERSPECTIVES ON ENVIRONMENTAL SECURITY

Throughout the environment and security debate, many writers have been critical of linking the two terms. Researchers and analysts from a traditional security perspective tend to discount the role that environmental degradation or resource depletion plays in precipitating violent conflict. They further argue that broadening the definition of security to include a laundry list of modifiers (environmental, ecological, economic, food, human, comprehensive, common) undercuts the term's utility by making it mean something different to each of multiple constituencies. Military critics of tying environment and security together also claim that performing environmental missions takes time and resources away from preparations for the traditional war fighting mission and therefore undermines preparedness and effectiveness in battle.

Environmental critics also claim that there is little evidence to support the argument that environmental degradation or resource depletion has a significant role in causing violent conflict, and especially interstate conflict. Furthermore, the methodological shortcomings of much of the research undermine the findings that do support a case for linking environment and violent conflict. Critics also fear that propagating the term *environmental security* could lead to the militarization of the environment rather than the greening of security. Military institutions, instead of undergoing fundamental change to re ect new security priorities, are more likely to co-opt and weaken the non-statist, non-threat based, cooperative ethic of environmental rescue. This criticism is reinforced by the perception that security institutions are searching for new missions to justify their high Cold War funding levels. Environmental critics also decry the conception of environmental security that has developed as an uniquely Northern and Western term; it is viewed as unacceptable to the South as a paradigm for environmental problems.

CRITICISMS OF REDEFINING SECURITY IN ENVIRONMENTAL TERMS

Critics commonly point out the greater likelihood of the militarization of the environment than the greening of security as northern security institutions search for new missions in the post Cold War period. The term as it is used in this context is Wand ver s (1995). Others share the concern expressed by the term with their own distinct critiques (Deudney, 1990, 1991; Dalby, 1992, 1994; Finger, 1991, 1994; Conca, 1994; Lipschutz, 1995; Gleditsch, 1997). With environmental security being used as a political slogan to gain attention for the environment, the risk is that the historically powerful military institutions will co-opt the green rhetoric rather than willingly giving up resources to more effectively address the new threats to environmental security. Some observers suspect that security may be redened to include environmental considerations merely at a rhetorical level (i.e., national security strategies) but would fail to produce a simultaneous reorientation or dismantling of security institutions and mindsets (Conca, 1994; Finger, 1994; Kakonen, 1994).

More broadly, some critics charge that environmental security encompasses too many problems and threats; for example, problems associated with infectious disease, global warming, environmental damage during war, deforestation, water scarcity, and nuclear waste. With such diverse problems included as the focus of environmental security, the term loses meaning and utility as an analytical tool because there is no delineation of what is included and what is not (Deudney, 1991; Dokken and Gr ger, 1995; W ver, 1995). Instead, linking environment and security merely represents a normative slogan conveying the urgency of addressing global problems in determining the priority of political battles (Levy, 1995a,b).

This criticism illustrates how environmental security is held to different standards for different purposes. Those in academia criticising environmental security as a normative political slogan are asking that the term perform as a sharpened theoretical tool. They discount the early calls for rede ning security, sometimes termed the rst wave of environmental security literature, as undeveloped, a conceptual trick or minimally useful (Levy, 1995; Gleditsch, 1997). From a policy perspective, the rhetorical use of the term is less troubling than the failure by its adherents to suggest speci c policy priorities and interventions which would accompany any rede nition.

The above criticisms arise from authors who assign a high priority to the importance of coming to grips with global problems. However, others continue to find considerable utility in the purely statist and militaristic security assumptions and therefore oppose widening the purview of security to new and different threats (Walt, 1991). They argue that while the Cold War has ended and the dangers of a bilateral stand off have abated, emerging military threats demand a traditional definition of security with continued priority support for the military. Nuclear, chemical and biological weapons proliferation, terrorism, and ethnic conflict remain reasons enough not to dilute the definition of security with peripheral, non-military concerns.

There are also criticisms of environmental security, which are based on the perspective of the South. Egyptian diplomat Saad (1991), for example, argues that invoking the term *environmental security* represents a new Northern justification for continuing the inequitable power relationship between North and South. She worries that wealthy countries of the North can afford to care about the environment and will undermine the international legal principle of sovereignty in the name of a higher goal called *environmental security*. The principle of sovereignty, from the perspective of the South, provides some defense against exploitation by recognizing each state, no matter how weak in capabilities, as the legitimate authority for control over the resources within its borders.

By this reasoning, Northern states may be tempted, in the name of environmental security, to try to dictate the patterns of natural resource usage, development priorities and population policies to developing countries. The stability and welfare of some states rest on sets of social power relationships surrounding the utilization of natural resources (large, politically empowered landowners in Brazil, for example). The elite in certain countries may therefore find an alteration of past social bargains, for the sake of environmental conservation, to be a larger threat to state security than the environmental destruction itself (Conca *et al.*, 1995). Such perspectives raise barriers to obtaining the cooperation of the South with respect to addressing global environmental problems under the guise of environmental security. This argument implicitly recognizes the importance of national or regional perspectives in defining or operationalising environmental security. The content and meaning of environmental security varies across nations and regions. These differences present difficulties when trying to mobilize action on a global scale under the label of environmental security.

> Twenty years ago, the emphasis was on ending the pollution that the industrialized North had been inflicting on the nations of the South. The goals were clean air and water and arable land, the requisites of a decent life; and the modality was international cooperation. Today, however, the North has seized hold of environmental issues by using them to cloak its own security concerns.
>
> (Saad, 1995, 273)

The prominent focus on environmental stress and violent conflict in the environmental security literature also presents an additional cause for Southern suspicion of the term. The North's concern with environmentally induced conflict can easily be viewed as a convenient means to distract attention from Northern environmental problems. High rates of consumption in the North or the historical depletion of resources do not figure prominently in causal models, yet they are integral elements in the larger environmental picture. Global issues such as climate change and stratospheric ozone depletion are not often recognised as salient issues in environmentally induced conflict because their long time lines guarantee marginal relationships to violent conflict. The sources for these global problems tend to emanate disproportionately from the North. Furthermore, Northern interest in environment and conflict linkages often extends only to a concern for regime stability and international security implications. The operationalization of environmental security within the traditional security institutions may stop short of fundamental interest in Southern problems of resource degradation and depletion, poverty, and the inequitable distribution of wealth.

ENVIRONMENT, HUMAN SECURITY AND SUSTAINABLE DEVELOPMENT

The World Commission on Environment and Development (WCED, 1987) and the United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro in 1992, have reinforced the notion that economic development is necessary to improve quality of life and well being. However, to be sustainable, this development must incorporate environmental, social, political and economic considerations consistent with a strong commitment to equity and a concern for resource limitations and the viability of ecosystems. Indeed, it is well accepted that environmental, social, political, and economic systems are interlinked; any actions involving one of these necessarily affects the others. Even our perspective on environmental change is constrained by social, economic, political and cultural factors; for example no universal definitions of degradation, scarcity or even pollution exist. These terms are defined by context and value systems.

This multi-dimensional characteristic implies that the question of whether environmental degradation is a cause of conflict is misguided. What we should be asking is whether environmental change (linked to a range of other factors) contributes to social tensions, and whether these tensions

may result in instabilities (and, quite possibly, conflict). The past decade of discussions on sustainability have further taught us that any assessment of how environment and security are related must take into account how these other factors influence sustainable development and, in particular, how growth must acquire both environmental and social meaning.

A particularly relevant criticism of the existing literature is that the debate on environment and security has largely ignored a discussion of how environmental security fits into the broader context of international development, social welfare and sustainable development. Although there have been calls for attention to comprehensive security (Westing, 1986) and a multilevel approach to security (Gr ger, 1996), most authors fail to recognize the one overwhelming argument in favor of linking environment and security: environmental problems must always be presented from within a broader perspective that encompasses various forms of equity, including world poverty . This is because poverty and inequity are two of the key factors contributing both to environmental change and to tension and insecurity throughout the world. For research on environment and security to gain social legitimacy, it must incorporate elements of social justice. In turn, for development to be sustainable, it must include the protection of human rights. These concerns are embodied in the broader concept of environment and human security. What is human security?

A further issue that has received little attention in the literature is that space matters. Some authors have recently called for a reshaping of our spatial perspective on linking environment and security. There has been a strong plea for regionalism (sub-national and supra-national) which should be decided on the basis of eco-geography (Dokken and Gr ger, 1995). Here eco-geography implies that the region of concern is defined by ecological boundaries (e.g., watershed or eco-region) and not simply political boundaries. Regionalism need not be confined to ecological regions; it may incorporate ethnic or other factors as well. Perelet (1994) also argues that environmental security problems must focus on the ecosystem level. It has also been suggested that research must focus on the local level or at least at the lowest possible spatial scale for the insecurity/conflict being studied. This has been termed the *subsidiarity principle* (Mische, 1989; Dokken and Gr ger, 1995). For example, the relationship between environment and poverty must be viewed locally and in the context of broader human security dimensions. This is absolutely crucial if we desire to incorporate local knowledge and make the process of development a truly participatory one. These two trends have stimulated further questions on the relationship between environmental security and the goal of a sustainable society.

ENVIRONMENTAL CHANGE AND HUMAN SECURITY

So where does this leave the link between environment and security? Coincidental with the claim that environmental degradation may be a threat to conflict/security has been the move to interpret security more broadly to encompass notions of human welfare, where there is no immediate prospect of armed conflict. A better way of framing the issue might be in terms of insecurities (Gr ger, 1996; Lonergan, 1997). As noted above, the appeal of a broader notion of security, framed in terms of insecurities, is obvious. It allows one to include the key issues of equity and impoverishment, along with other non-conventional threats to security. It also is multi-dimensional (and multi-level according to Gr ger, 1996); this allows us to introduce into the debate issues of human, environmental and social rights, acting at all spatial levels, from the individual to the global. However, as noted above, many authors have expressed significant concerns with using a broader definition of the term *security*.

But even accounting for these concerns, it is clear that there remains a need to reassess our traditional perspectives of security and focus more on the insecurities posed by non-conventional threats. We must also recognize that society is in a profound period of rapid social, economic and environmental change. While continued growth in gross world product may imply improvement in social welfare, there are many disturbing indications that this is not the case for much of the world's population. The number of wars has increased dramatically over the past three decades. However, since 1960, these have primarily been intrastate conflicts, where inequity is a key feature.

This leads to the inescapable conclusion that while environmental degradation and even resource depletion as causes of conflict may be overstated, it is undeniable that increasing inequities in society are likely a major source of these (and other) non-conventional threats to individual security. At the same time, there is recognition that traditional approaches to national security may not, in turn, ensure the security of individuals and communities. This applies to global efforts aimed at curbing global warming and ozone depletion to local sustainable development initiatives. Again, this calls for a broader notion of security, one that focuses on the human element, despite the ambiguities and difficulties this may cause.

Environmental Sociology

Amar Wahab
University of Toronto, Toronto, Canada

Environmental sociology is the study of reciprocal interactions between the physical environment, social organization and social behavior (Sydenstricker-Neto, 1997). Unlike a sociology of environment perspective, which applies traditional social theory to the study of environmental issues, it focuses on the interaction between social and environmental systems. According to Hannigan (1995), the field of environmental sociology still lacks a seminal work which could lift it into the mainstream of debate in the broader field of sociology. Sociologists therefore engage in environmental issues with the aim of enriching mainstream sociological theory, rather than attempting to ambitiously transform the discipline. A defining feature is the work of Dunlap and Catton to replace an anthropocentric approach (Human Exemptionalism Paradigm) with their ecocentric, New Ecological Paradigm. Although this approach has been viewed as over-ambitious, it has stimulated and catalyzed a diversity of paradigms and theoretical approaches to the study of environmental sociology.

Buttel (1987) has cited ve key areas of environmental scholarship:

1. Dunlap and Catton s new human ecology;
2. environmental attitudes, values and behaviors;
3. the environmental movement;
4. technological risk and risk assessment;
5. the political economy of the environment and environmental politics.

Alternatively, Hannigan (1995) has identi ed two distinct problems as central to the existing literature on environmental sociology: (1) the causes of environmental destruction; and (2) the rise of environmental consciousness and movements.

The new ecological paradigm explanation of environmental destruction focuses on the competing functions of environment as supply depot, living space and waste depository within an assumed global carrying capacity (Dunlap and Catton, 1979). This model is concerned with the increasing globalization of environmental problems and the increasing production of waste, but is criticized for its limited incorporation of social de nition. An in uential alternative explanation, deriving from political economy, emerges out of Marxist ideology which identi es industrial capitalism, in which the corporation and the state can be seen as being in opposition to its own citizenry, as the major cause of environmental degradation (Hannigan, 1995). In this explanation, capitalism is said to generate *the treadmill of production* (Schnaiberg, 1980), which operates regardless of the carrying capacity of the ecosystem.

The second problem currently tackled by environmental sociology, looking at environmental consciousness and movements works with an array of hypotheses. Perhaps one of the more in uential of these is the new middle-class thesis which has focused on the conceptualization and constitution of new social movements (NSMs), i.e., activism by individuals and groups who are deemed to possess post-materialist values. According to Hannigan (1995), there have been environmental sociologists such as Steninmetz (1994) who have contested the class basis of NSMs

activism and others such as Habermas (1987) and Beck (1992) who have suggested that NSMs have emerged in marginal spaces, in a culture of political closure organized by the corporate state (which may help to explain their relative ineffectiveness). Hannigan has also employed a social constructionist perspective, which focuses on the social, political and cultural processes by which environmental conditions are defined as risky and actionable. He views the construction of environmental problems and conflicts as hinged on the processes of assembling, presenting and contesting claims.

It is important to note though, that the discourse on environmental sociology has been primarily focused on environmental problems in the economic North, with very little reconceptualization based on the works of third world scholars and integration of development discourses in the South. Criticism surrounding some of the silences regarding interlocking systems of race, space, gender, sexuality, class and other social axes of power that are embedded in the rubric of alternative discourses is less than forthcoming. Some of the themes which have been popularized by environmental sociology involve environmental problems related to agriculture, energy and fuels, hazards and risks, leisure/recreation, natural resources, social impact assessment, and sustainable development. Some central works in the field of environmental sociology include Dunlap and Canton (1979), Hannigan (1995) and Schnaiberg and Gould (1994).

Equity

Henry Shue
Cornell University, Ithaca, NY, USA

Intense debates about the requirements of equity have been at the very heart of the international negotiations about what to do about rapid climate change, ever since those negotiations began in the 1980s. In this context, equity, distributive justice, and fairness are alternative terms for the same set of requirements. Economists and lawyers tend to use the term equity, and philosophers normally discuss distributive justice, but these disciplinary preferences in terminology have no systematic signi cance. In both cases, the professionals are talking about what ordinary people call fairness.

Equity, or fairness - the terms are employed interchangeably in this article - is a feature that the division of an aggregate or total among multiple parties often ought to have. Fairness is an ethical requirement to be met by speci c, concrete allocations, divisions, or distributions of bene ts and burdens. The fundamental point about fairness is that what matters is not the average per capita distribution of some aggregate, which tends to be the focus of economic analysis and which, after all, is a merely theoretical distribution, but the relative sizes of the actual shares of the aggregate that various parties each have.

Multiple questions usually arise about fairness. What is a fair result (substantive fairness)? What is a fair process (procedural fairness)? What connection, if any, is there between substantive and procedural? In the case of climate change, the multiple tasks required can each be performed by means of fair or unfair processes, and with fair or unfair results; these tasks include the allocation of the costs of adaptation to actual climate change, the allocation of the costs of the mitigation of potential climate change, and the allocation of the limited total of emissions of greenhouse gases compatible with mitigating climate change. Winners and losers will be spread both across the geographical dimension, including the international, and along the temporal dimension, including the intergenerational. How they will be spread is uncertain but will be deeply affected by the political decisions made under the Framework Convention on Climate Change. Many of those decisions can consequently be assessed as fair or unfair. Since the maximum severity of climate change will depend upon the date of the technological transition away from the energy technologies that worsen the problem, the fundamental question of intergenerational fairness is whether policy options, like the exibility mechanisms in the Kyoto Protocol, advance or delay this date of transition.

MULTIPLE QUESTIONS

Fairness can be a feature of an outcome: the question is then whether the various parties among whom some total is to be divided each receives a fair share. That is the question of *substantive fairness*. On the other hand, the question of fairness sometimes applies to the process that produces the outcome: this question is whether the manner by which the total is divided among the various parties is fair. This is the question of *procedural fairness*.

Complex and important questions arise about the relation, if any, between procedural fairness and substantive fairness. Sometimes, in one kind of case, the basis for judgments of substantive fairness and the standards for judgments of procedural fairness are independent of each other. Substantive fairness and procedural fairness can each be specified separately. For example, if a murder has been committed and someone is to be punished, the only substantively fair outcome is for the punishment to be inflicted upon the murderer, the guilty person. Most societies have elaborate standards for the procedural fairness of murder trials – standards like a presumption of innocence for the accused, and adequate opportunity for the accused to make a defense. Yet, tragically, it is entirely possible for a perfectly fair trial – a trial satisfying all the standards of procedural fairness – to lead to the conviction of an innocent person, which is a substantively unfair outcome: the punishment of the innocent. Even the procedurally fairest systems of criminal law are fallible and sometimes reach substantively unfair outcomes by convicting innocent persons. Here procedural fairness does not guarantee substantive fairness.

By contrast, in other kinds of cases there is no basis for judging the fairness of outcomes that is independent of the fairness of the procedure that produces the outcome. A lottery is the clearest example. Suppose a prize is to be awarded by having everyone who wants the prize place a piece of paper with his/her name on it in a hat and having someone who is blindfolded pick one name. It makes no sense for someone whose name was not selected to say after the drawing that the outcome is unfair because the wrong person won the prize. There is no wrong person if the lottery was conducted fairly, as there is when an innocent person is convicted. The only standard of fairness in the case of a lottery is procedural fairness: the right outcome is whatever outcome results if the process is conducted fairly. Here fairness is randomness. In the case of a lottery, by contrast with a criminal trial, there is no such thing as a person who, in advance of the drawing, somehow ought to be selected for the prize, analogous to the person who, in advance of the criminal trial, ought to be chosen for the punishment.

Sometimes, of course, when the prize in a lottery goes to someone who does not need it, and other participants in the lottery do need it, objectors say too bad, the prize should have gone to someone who needed it . If this is to have any solid basis, it must be construed as an objection to this use of a lottery process. If the prize genuinely ought to have gone to someone needy, then no lottery should have been conducted at all (or participation in the lottery should have been restricted by the rules for the lottery to people who needed the prize). The objectors, then, are contending that what had been treated as a prize in a lottery ought not to have been made a lottery prize because, in fact, a relevant basis for judgments of substantive fairness, namely need, was available; therefore, instead of having held a lottery that awarded the prize randomly, a completely different kind of process should have been used to allocate the prize to someone who needed it. Defenders of the lottery might be able to reply that although some things sometimes ought to be allocated according to need, this lottery prize is not one of them, and nothing is wrong with using a fair lottery to award it. This is now a debate about a choice among processes and about the relevance, if any, of a particular substantive basis (need) to that choice of process (see Box 1).

MULTIPLE TASKS

The global effort to deal with climate change simultaneously faces several challenges that can be distinguished from each other in theory but must all be handled in practice by means that are at least complementary, if not mutually supportive. Each of these tasks raises all three kinds of questions about equity. Since climate change is already occurring, and since current concentrations of greenhouse gases in the atmosphere constitute a commitment to additional climate change, one task will obviously be adaptation to climate change. Adaptation will require expensive adjustments, and one cluster of questions about equity concerns the division of the costs, and the benefits, of adaptation (see Box 2).

MULTIPLE DIMENSIONS

The negotiations about whether to take effective action concerning climate change are conducted by national governments; and measurement and reporting of sources, sinks, and net emissions are all categorized in national terms. Consequently, it is difficult to overlook the fact that equity issues have dimensions that are spatial: the international distributions of costs and of emissions. Many debates about the international division of the benefits and burdens have been pure conflicts of national interest, even when sometimes clothed in the rhetoric of equity. International equity will be attained only if powerful national states aim explicitly at it; nothing supports any hope that the pure clash of national interest will somehow lead to international equity. Nevertheless, even the nations that are too weak to defend

Box 1 Multiple questions

Substance

Procedure

Relation between first two

In the case of climate change, some of the fundamental issues about equity concern disputes of the kinds illustrated in the text. Many economists assume that the use of efficient markets is analogous to the use of a fair lottery, in that whatever distribution results is unquestionably acceptable; this is equivalent to assuming that there are no well-grounded principles of substantive fairness by which market outcomes can be assessed. Much of the support for the flexibility mechanisms in the Kyoto Protocol (Clean Development Mechanism [Article 12], Joint Implementation [Article 6], and Trading in Allowed Amounts of Emissions [Article 17]) appears to rest on such an unargued assumption that whatever consequences for the allocations of costs and of emissions are generated by fair processes are unchallengeable on grounds of substantive fairness. This flies in the face of the solidly grounded view that, for as long as the generation of greenhouse gas emissions is essential to human subsistence, every person needs to benefit from at least a minimal level of emissions. If the global ceiling on total emissions is sufficiently low, the only distribution that could possibly guarantee everyone the necessary minimum would be an equal distribution. To guarantee that minimum, market processes need to be restrained by universal inalienable rights to benefit from a minimum level of emissions.

One needs to determine for each situation not only: (a) whether grounds for judging substantive fairness are available – and if so, what they are; and (b) whether standards for procedural fairness are available – and if so, what they are; but also (c) in which cases internally fair processes are adequate, meaning that whatever outcome they produce is therefore acceptable, and in which cases substantive fairness should be the basis for adopting one kind of process rather than another, meaning that a process, even if internally fair, is fully adequate only if it is the best means to fair outcomes.

themselves successfully against unfair treatment at least have official representatives (see Box 3).

INTERGENERATIONAL EQUITY AND INNOVATIVE TECHNOLOGY

A deeper point about technology is buried in the second tendency. The basic decisions concerning climate change are choices about energy technology. Choices about which nations are to bear the current costs of technological transitions obviously implicate international equity; and choices about the rate of technological innovation deeply affect intergenerational equity in a less obvious way. The second tendency ingrained in current approaches to climate change is not to abandon fossil-fuel technologies until their continued retention becomes too expensive for the current generation, and meanwhile to avoid investing very large amounts in research or development of alternative energy technologies. This clearly favors the current generation strongly, although the issue of fairness is whether this favoritism is unreasonably strong. This tendency and the first tendency (to select lowest-cost-first solutions) are related; the first supports the second – it is believed to be cheaper to continue to spread into the less-developed states the current form of industrialization that depends on fossil-fuel than to introduce alternatives. However, many other factors, including entrenched political and economic interests and lack of imagination, also underwrite retention of the familiar fossil-fuel technology that is the most important contributor to climate change. The primary issue of intergenerational equity here is not, however, merely the obvious one of deferring costs so that they fall upon generations later than one's own, although that is an issue too.

Sooner or later, human societies will make a transition from reliance dominantly upon fossil-fuel-driven technologies to reliance on one or more alternative energy technologies. The issues are: at what point in history should this transition be made (substantive intergenerational equity)? how should this date be determined (procedural intergenerational equity)? The current tendency is to allow the date to be determined by relative prices in energy markets. The general idea, according to abstract assumptions in economic theory, is that at some time the prices of fossil fuels will have risen high enough, and the price of some alternative energy will have dropped low enough, that rational consumers will switch to the alternative energy source. The price of alternative energy will have dropped, relative to fossil fuel, because at some point entrepreneurs will have realized that investments in this kind of technological innovation could then be profitable in the relatively short-term. The date of the transition, according to most economists, ought to be determined by the prices – prices are the right basis given the moral assumptions underlying economic theory.

Consideration of intergenerational equity, on the other hand, might suggest that, depending upon many complexities that cannot be explored here, political action ought to be taken to advance the transition to an earlier date. One critical issue is whether human societies can continue to rely predominantly upon fossil fuels for a significantly longer time without making the severity of climate change greater than it otherwise would have needed to be. In other words,

Box 2 Multiple tasks

Costs of adaptation

Costs of mitigation

Allowed emissions

Relation among first three

One means toward controlling the costs of adaptation is abatement, or mitigation, of climate change. Adaptation tackles the effects of climate change; mitigation attempts to slow the rate of climate change itself. Obviously mitigation and adaptation are not separate matters; for example, the less mitigation accomplished, the more adaptation required, other things being equal. Nevertheless, the allocation of the costs and the benefits of mitigation need to be considered independently from the costs and the benefits of adaptation because, to mention only one consideration, any reasonable basis for dividing the costs of mitigation might be different from any reasonable basis for dividing the costs of adaptation. At least in theory it is possible that the parties who ought to bear most of the costs of adaptation are different from those who ought to bear most of the costs of mitigation.

These first two tasks fundamentally concern the fair sharing of financial burdens and benefits. The substantive question, in both cases (adaptation and mitigation), is: who pays? The procedural question in both is: how is it to be determined who pays? The third profoundly important allocative task is the distribution of greenhouse-gas emissions themselves, and, thus, of the activities that produce the emissions. Who is allowed to emit what portion of the global total of allowable emissions? If rapid climate change is to be avoided, an enforceable ceiling must be imposed by the international community on the global aggregate of emissions. That total must, in turn, be divided somehow among the people of the world. For as long as economic activity depends upon the burning of the fossil fuels that emit greenhouse gases, the fair distribution of this limited total has unsurpassed importance. One crucial consideration is that powerful states are unlikely to restrict themselves to the shares they are allocated unless their allocation seems reasonably fair. The simplest way for the distribution to seem fair is for it transparently to be fair. Equity may be politically essential to effectiveness. A second crucial consideration is that, with the overall total severely limited, those who exceed their own fair share will, in fact, be depriving others of their minimum entitlement, unless those others make up for the encroachment by exceeding the mandated total and thereby frustrate the ultimate purpose of the entire effort.

Finally, just as the realization that questions of equity must be analyzed into substantive and procedural leads to the further question about how the two are to be related, the realization that the tasks of equity need to be distinguished into fair allocation of adaptation costs, fair allocation of mitigation costs, and fair allocation of the emissions themselves leads to the further question: how, and/or on what basis, are these three tasks to be related? Is there a fair, coordinated solution to all three problems?

Box 3 Multiple dimensions

Spatial (International)

Temporal (Intergenerational)

Relation between first two: date of technological transition

The temporal dimension of equity is more easily forgotten, but nothing affects more human beings than the intergenerational distributions of costs and of emissions. Indeed, future generations are usually the unrepresented, and, therefore, most vulnerable parties of all, in spite of the fact that the unnoticed other side of the coin in most of the decisions made about how much burden the current generation will handle, is how much is consequently left for succeeding generations to bear. For example, every decision about the relative emphasis to be placed on (present) mitigation efforts as opposed to (future) adaptation efforts is also a decision about the intergenerational allocation of effort and resources. Two tendencies deeply engrained in the current approaches to climate change shift the burdens toward our grandchildren, and their grandchildren, especially strongly.

The first tendency is the largely unquestioned assumption that it is only rational always to pursue least-cost-first solutions to mitigation. While this may often be rational if no interests are given full weight except the interests of the current generation, it is far from evident that such solutions are rational in light of the interests of future generations or are equitable to them. The danger to the future has two aspects. First, if the level of expenditures were fixed independently, then the choice of a least-cost-first approach would at least mean that, for the given expenditure, the most would be accomplished. In reality, however, nothing keeps expenditures fixed, and consequently, many parties will choose to accomplish the same amount of mitigation for a lower expenditure rather than accomplishing more mitigation for the same expenditure. The result is not that more is accomplished to slow climate change but only that less is spent now. Second, least-cost-first can mean higher-cost-later, unless technological advances that reduce the costs of the currently more expensive tasks at least keep pace with the passage of time. Spontaneous technological advances might occur in time to contain costs for future generations, but simply to assume net technological progress would be a largely groundless gamble for which future generations will pay if it turns out badly.

is it the case that the more distant the date of the transition away from fossil fuels, the more severe climate change will become before it stops worsening (because of the greater maximum atmospheric concentration of greenhouse gases)? This depends upon whether, during the period of the continued predominant reliance on fossil fuels, society is willing and able to cap its greenhouse gas emissions at a level that does not make climate change progressively worse by continuing to expand the atmospheric concentration. This is an open question, the answer to which will be determined by decisions yet to be made.

However, those decisions could make matters much worse for future generations than they would be if a political initiative was taken to move the date of transition to an earlier time. If: (1) the choice is made to take no political action to advance the date even though the price of alternative technologies becomes competitive with the price of fossil-fuel technology; and (2) the choice is made, meanwhile, to allow the annual rate of emissions to remain high enough to continue to increase atmospheric concentration, then in order to avoid mitigation costs for the current generation, much higher mitigation costs will have been imposed upon future generations. This appears to be a compound injustice toward our descendants.

Exxon Valdez Oil Spill

The spill of crude oil from the Exxon Valdez is probably the world s most infamous tanker disaster, although it was not the world s largest oil spill. In the minutes after midnight of March 24th, 1989, the Exxon Valdez, its captain intoxicated, ran its single hull onto a shoal in the northeastern portion of Prince William Sound, off Alaska. The tanker was carrying nearly 1.3 million barrels of North Slope crude oil. Fully one- fth of that cargo spilled into the sound: 11.2 million gallons of crude (42 million liters). Initially, there were hopes the crude could be contained due to the relatively calm seas. But three days after the Exxon Valdez ran aground, strong northeasterly winds blew up and dispersed the oil hundreds of kilometers from the accident site. The mixing of oil and water, agitated by wind and wave action, created a substance known as *mousse* which was carried 750 km (470 miles) from the grounding site. The oily mixture washed ashore along a huge expanse of Alaskan coastline, from Prince William Sound to southern Kodiak Archipelago and the Alaska Peninsula. Thousands of sea birds and mammals were killed by the oil. Hundreds of volunteers attempted the rescue and recovery of oiled birds.

Exxon spent tens of millions of dollars in attempted remediation, including sand blasting of beaches. The cost of clean-up had a positive economic effect on the state s gross national product (GNP), generating more economic activity than if the cargo had safely reached its destination. Within Prince William Sound, 790 miles (1271 km) of shoreline were oiled, as well as another 2400 miles (3862 km) of shoreline in the Kenai Peninsula Kodiak Archipelago region. Long-term studies continue about the impact of the spill.

Francis of Assisi

(1181- 1226)

Francis of Assisi, Saint, mystic, cleric, was born at Assisi (Italy) to a wealthy merchant family. It was assumed that he would enter the family business, although apparently for a time he was a troubadour and soldier. In 1201 he took part in an attack on Perugia where he was taken hostage and held for a year. It was during this period that he began to turn to religion, although after his release he enlisted in another military venture. It was at this time that he had a dream in which God called him to do His works. He returned to Assisi and began to care for the sick. In 1206, he had a vision in which Christ called on him to repair his church, which Francis interpreted as being the Church of San Damiano, near Assisi.

He devoted himself to repairing the church. Francis gave up his rights and possessions, and then began to preach. He was joined by others and his group soon numbered eleven, it was then that he gave them the short Rule (a set of rules of conduct for his new order). Pope Innocent III granted approval for a brotherhood, called the Friars Minor. Although based at Assisi, they preached across central Italy calling for the return to a life of Christ, one that emphasized simplicity, poverty, and a faith in God's care, rather than possessions. In 1212 Clara Sciffi, inspired by his devotion, joined Francis and formed the Poor Clares sisterhood. In 1219 Francis journeyed with crusaders to the Near East.

The brotherhood grew into an order, and larger numbers were attracted to Francis' message of simplicity in life, poverty, piety, and humility before God. He wrote a more detailed Rule, which in time was further revised by new leaders of the Franciscans. In this time he also became known for his walks in the woods and hills, and his sermons to birds and animals. What is more likely is that he preached about nature rather than to it. In nature Francis saw the work of God, and to abuse or defile God's creatures was an affront to God and an act of debasement. Francis saw nature as an extension of God. Understanding the beauty and spirituality of nature was for Francis an integral part of his devotion and piety. His vision of God's world was based on a trust in God's love and he believed that poverty (taking no thought in tomorrow) would enable him to experience that love most fully. This linked him to the poor and disadvantaged and remains a strong part of his appeal today.

Later, he gave up leadership of the Order and went to the mountains to live a life of secluded prayer. For Francis, his life in the hills and forests brought him closer to the essence and presence of God. It was in the wilderness

that he received the stigmata (wounds of Christ). He did return to visit the Franciscans, and also had a small group of followers. In the fall of 1226 he died at Porziuncula, near Assisi.

Regardless of Francis' original beliefs, he is today considered by many to be the Patron Saint of ecology. For example, his name served as the rallying point for efforts such as the Assisi Declaration from the World Wildlife Fund's anniversary gathering at Assisi (in September 1986).

KEVIN HANNA *Canada*

Friends of the Earth

Friends of the Earth (FoE) was founded in 1969 in the United States by former Sierra Club Executive Director, David Brower (*see* Brower, David, Volume 5). Although the organization and Brower ultimately had a well-publicized and acrimonious parting, it lived up to its founder's vision of an effective family of national groups within an international organization.

By 1988, the organization had established relatively autonomous member organizations in 61 countries, all within an international federation; FoE-International (FoEI). One of FoE's clearest successes has been the spread of the network to countries in the developing world, and a relatively democratic decision-making structure between and among national FoEs. Expansion to the south took off after the 1986 annual general meeting, which was hosted by the Malaysian FoE, Sahabat Alam Malaysia. FoEI was also one of the first international environmental groups to recognize the need to support developing civil society in the former USSR. Although founded in the US, FoE's international headquarters is in Amsterdam. Combined global membership in 1988 was close to one million, and the combined annual budget of FoEI was nearly $200 million (US), with 700 full time staff members.

FoE, like Greenpeace and the Sierra Club, is prepared to tackle a wide range of concerns, from forests to pesticides, climate change and ozone depletion to nuclear energy, and the damming of rivers. FoE's US head office in Washington, DC has developed a global leadership role in non-governmental organization (NGO) campaigns to reform the environmental policies of Export Credit Agencies and international financial institutions. Its US Executive Director, Brent Blackwelder, was arrested in the Washington protests against the World Bank and the International Monetary Fund in the spring of 2000. FoE (UK) has been in the lead in protesting genetically modified foods. FoE's style is campaign driven, not corporate. It aspires to grassroots activism buttressed by effective national and international campaigning.

Futures Research

Allen Tough
University of Toronto, Toronto, Canada

Futures research is a small but vibrant field of inquiry, theory, and practice. It does not predict or promote one particular future. Instead, it studies a wide range of potential or alternative futures. Sometimes these are spelled out in the form of stories about the future, usually called future scenarios or images of the future. Often one or two of these will be very positive, one or two very negative, and the rest somewhere in between. Some of these scenarios are more likely than others, of course, but often these are the negative ones. This exercise can help us choose our preferred futures and work toward making them actually happen.

Long-term global environmental change plays a key role in almost every future we can imagine. Climate patterns, water, food, species and oil affect almost every scenario. Similarly, various possible socio-economic and political scenarios will have major effects on the global environment. Various futures for science and technology, too, could greatly affect the environment. If nanotechnology succeeds in building things atom by atom, molecule by molecule, it may enable us to transform toxic wastes and improve the environment cheaply and easily – a scenario that sharply differs from the usual long-range forecast.

For understanding global environmental change, futures research is most useful when it focuses on a horizon between 30 and 100 years from now. Shorter term scenarios can more easily pretend that the environment is not an important factor. At the other extreme, one can be fairly sure that global environmental change will not be high on the agenda for public policy 1000 years from now: either it will have been solved much earlier or we simply will not be here.

The field of futures research arose from the need for post-war planning in the late 1940s. In its early decades, it dealt largely with positive images of the future. The largest conference of futures researchers in history was held in Toronto in 1980; about 5000 attended. Even at that stage, very few of the papers mentioned war, environment, or population growth as major problems.

Now the field has matured, although it is still remarkably small in light of humanity's needs for thoughtful long-term planning. The major international organization for futures researchers is the World Futures Studies Federation. The Future Generations Program at the University of Malta holds regular conferences and in 1997 encouraged the United Nations Educational, Scientific and Cultural Organization General Conference to adopt a declaration on the responsibilities of the present generations towards future generations. The Foundation For the Future studies the major factors affecting society over the next 1000 years. Although various university departments offer single courses on futures research, under a variety of titles, only a few graduate programs in the world focus on futures research.

Because it focuses on humanity's long-term future, or on future generations, futures research can provide a crucially important perspective to our understanding of global environmental change. By forcing us to look far ahead, futures research makes us realize the crucial need for achieving a sustainable society (and an appropriate size of population) that does not exceed the long-term carrying capacity of our environment and resources. In this way, we can give future generations an opportunity equal to ours instead of a devastated planet crowded far beyond that of today. Ideally we would like to see human well-being and the quality of life improve around the world over the next few decades, but at least we can try to ensure that they do not markedly decline. If we fail to make the needed changes – if massive permanent deterioration of our physical environment and resources occurs – then future generations could be much worse off than we are.

At times, individuals and societies make certain choices because of immediate benefits. At other times people look ahead and wisely give up some immediate benefits because of greater long-term benefits. Futures research encourages this longer-term or future generations perspective. Within such a perspective, longer-term decisions make excellent sense, both at the individual and the societal levels.

Futures research employs a variety of approaches. Three of the most common are extrapolation, scenario-building, and the Delphi method. Computer simulation is not so common, partly because of its complexity, but it is particularly relevant for forecasting global environmental change.

Extrapolation involves simply continuing a series of trends into the future. The variables could be temperature, population, stock prices, or yield per hectare. In the short run, extrapolation can be very successful because the recent track record of a variable is often the best indicator of the next few months. But in the long run extrapolation becomes risky since many trends eventually reverse.

Scenario construction is a more creative futures methodology than extrapolation. At one extreme, creating a set of scenarios is quite similar to writing science fiction or future fantasy. It can be a deeply personal effort to build richly detailed stories of how things might unfold between the present and some future date. Alternatively, scenarios can be constructed by a group of managers or citizens in order to reflect on various possible futures for their company or region. They can be asked to construct the most likely futures, their preferred futures, the worst and best possible futures, or some combination. A global think-tank called the *Millennium Project* of the American Council for the United Nations University uses questionnaires, interviews, and scenario contributors from around the world to build its scenarios, presented in their annual State of the Future report (Glenn and Gordon, 2000). Many scenarios elicit strong emotions, ranging from Let's do everything we can to avoid that horrible possibility through to I'd like to devote my life to achieving that beautifully positive image of the future (*see* Scenarios, Volume 5).

The *Delphi method* involves repeated surveys of a panel of experts on likely future events and achievements, sometimes even on the most likely date that each will occur. Because the results of each round are fed back to the respondents in their next round, the expert opinions often move toward a consensus position. In order to take into account the ways in which variables and contingencies may influence the outcome, a Delphi study may add cross-impact analysis by constructing a matrix to show their interdependencies (Bell, 1997).

Computer simulation can be used to develop and manipulate models of the atmosphere, the biosphere, the economy, or a mix of all three. This approach usefully forces the futures researcher to explicitly and precisely state many assumptions. The resulting model can be used to answer questions about the likely outcome if certain changes occur in key variables or policies. What will happen to world resources and population, for instance, if we continue with the *status quo*, often called the *business-as-usual scenario*? (*see* Business-as-usual Scenarios, Volume 5) What if we truly shift to a policy of sustainability (Meadows *et al.*, 1992)?

G

Gaia Hypothesis

G R Williams
Guelph, Canada

Gaia was the name given in Greek mythology to Mother Earth. Thus, it is etymologically related to all our words pre xed with geo-, such as geography and geology. In 1972 James Lovelock appropriated the name Gaia for his concept that " the total ensemble of living organisms which constitute the biosphere (and) can act as ••• an active adaptive control system able to maintain the Earth in homeostasis" (Lovelock and Margulis, 1974a). This imaginative suggestion has gained considerable popular support but has been the subject of trenchant scienti c criticism.

The concept of Gaia arises as an attempt to answer two questions. First, how is one to account for the anomalous composition of Earth's atmosphere? The atmosphere of Planet Earth is anomalous in two respects. The mixture of gases in our atmosphere is far from chemical equilibrium. For example, over geological time, nitrogen and oxygen would be expected to react to form oxides of nitrogen. The coexistence of methane and oxygen in the atmosphere is an even more convincing example, departing from thermodynamic equilibrium by a factor of 10^{30}. The atmosphere of Earth is also anomalous in comparison with that of the other terrestrial planets, Venus and Mars. On these planets the composition of the atmosphere is close to chemical equilibrium. There is little free molecular oxygen (O_2) and the predominant gaseous species is carbon dioxide (CO_2). Lovelock suggested that the aberrances on Earth are caused by the activities of the global biota and that, more generally, the detection of such anomalies could be used as a criterion for the presence of life on a planet (Lovelock, 1975). The spectroscopic detection of thermodynamic anomalies in the atmospheres of planets orbiting other stars is now becoming a possibility. Such evidence would be a remarkable vindication of Lovelock's suggestion. The control experiment has already been performed: a fly-by of Earth by the spacecraft Galileo found profound departures from chemical equilibrium indicative of the presence of life (Sagan *et al.*, 1993)!

The second question to which the Gaia concept seeks to provide an answer is, how has life been able to persist on Earth for a period of at least 3.5 billion years? For this length of time the environmental conditions of the planetary surface must have remained within limits that life in its various forms could tolerate. As Lovelock and Margulis (1974b) noted:

> Stable temperature, pH and element cycling requirements for life must have been met on this planet for the entire recorded history of the Earth. Organisms found in extreme environments are highly specialized. If the Earth had frozen for even a few tens of thousands of years, or if hot acid springs had been widely distributed for even a single epoch, these occurrences would have been discerned from the fossil record.

This stability suggests a control system similar, for example, to those that maintain constancy in such characteristics as body temperature and the concentration of such blood constituents as hydrogen ions and glucose. This constancy of the internal environment, homeostasis, forms the model for the Gaian idea that the conditions of the external environment have been held within limits favourable to life since its origin 3.5–3.8 billion years ago.

The key point to Lovelock's use of the word Gaia is that it brings together two ideas. First is the idea of an adaptive control system analogous to the thermostatic control of room temperature, involving a sensor (thermostat) and effector (furnace or air conditioner). Such a system is inferred from the persistence of life through the geological record. Second is the idea that this control is exercised through the collective activities of the biota. Such control may be inferred, he suggested, from the anomalous chemical composition of the atmosphere. The two ideas are connected (for instance global temperature is profoundly affected by atmospheric composition) but it is essential to the Gaian notion that both be present. In Lovelock's view Gaia is not just a global control system (inorganic control mechanisms can be postulated) nor is it just the global biota. Rather, Lovelock suggests that the global biota, are responsible for maintaining the steady state (but non-equilibrium) properties of the surface of the Earth (Williams, 1996).

The idea of a living Earth, given a name that has religious overtones, has acquired considerable popular appeal. However, some concern has been expressed that an undue emphasis on the adaptability and resilience of the environment (and even its ability to heal itself) might encourage insouciance with respect to the deleterious effects of human activities. That Lovelock s concept is not consonant with those who would interpret Gaia as allowing unfettered human disruption of the environment is clear. However, within the Gaian scheme of things, the species *Homo sapiens* has no privileged position and a degree of stability consonant with the persistence of many forms of life might permit a range of environmental conditions incompatible with human existence. Environmental activists have focused attention on the central role ascribed to the global biota and on the name Gaia, which conjures up a sense of reverence for life. For instance, there is a *Missa Gaia* commissioned by and performed annually in New York City s Cathedral of St. John the Divine. A search of the World Wide Web for Gaia alone displayed 36 339 pages, and 1453 pages for the association of Gaia and Lovelock.

Within the scienti c community, the analysis of the Gaian hypothesis by geochemists and biologists has focused on a number of issues. The notion that a biota can play a catalytic role in determining planetary processes has become more fully appreciated. It has been recognized for many years that the oxygen of the atmosphere is derived from water through the biological process of photosynthesis. More recently, the seasonal uctuations in atmospheric carbon dioxide, that are such a conspicuous feature of the Mauna Loa record, have been recognized as testimony to the ability of the biota to in uence atmospheric composition. But scientists studying the important inorganic cycles of the planet have been reluctant to assign a signi cant role to the biota (Holland, 1984). More recently, as geochemists have started to analyze planetary issues from a systems analysis point of view (Kump *et al.*, 1998) focusing on biogeochemical cycles, Lovelock (1986) has suggested the term *geophysiology*, to bring together those focusing on such cycles with those searching for biotic control systems but the word lacks the mythological resonance that gives the earlier Gaian idea its impact.

It is this latter notion (of a global biotic control system) that has led to the strongest criticism of the idea of Gaia (Williams, 1996, Chapter 5). In early formulations of the idea, Lovelock did not hesitate to write both of control of the global environment by the biosphere (which might be uncontroversial) and of control for the biosphere . Insofar as the latter has teleological implications, i.e., it implies that the Gaian system exhibits purposiveness, this runs counter to mainstream contemporary biological thinking.

Indeed, if one wished to speak of a living Earth or Earth as an organism, it would be almost mandatory to present evidence of such purposiveness. Thus the real problem lies not with the implication of a purposeful Gaia, but with the absence of any account as to how purpose would be built into the Gaian organism. For those entities that biologists recognize as organisms, apparent purposiveness is accounted for by natural selection. Recently, evolutionary accounts have even provided an explanation for cases of cooperative activities of organisms in communities. In addition, cooperation among biotic components is seen in all multi-cellular organisms, which depend upon cooperation between the genes expressed differentially in the differentiated tissues. More relevantly, a similar cooperation can exist between genes in different organisms. However, such cooperation has been demonstrated only within communities of closely related individuals. A global organism would require intergenomic interactions among organisms of many very different species separated by long distances. To most biologists the possibility of such large-scale symbioses seems improbable to impossible.

The problem may be expressed in another way. Apparent purposiveness arises in living systems because the random mutation of genes throws up occasional variants that can survive and reproduce better than the original strain or can survive and reproduce in ecological niches inaccessible to the original strain. Such an evolutionary scenario for the *Origin of Species* has two prerequisites, time and genetic potential variation. There has been plenty of time, four billion years, over which action could take place. What the Gaian concept appeared to lack was a means of explaining the source of genetic potential variation (Ehrlich, 1991) (the grounds for selective success are not important if a means can be identi ed). Symbiotic cooperation may be as important as interspeci c competition, but there must be a vast reservoir of variation, and it must be heritable variation, on which cumulative selection can operate. (Note that the idea of interplanetary selection has never been proposed other than as a *reductio ad absurdum* (Dawkins, 1982)).

Watson and Lovelock (1983) attempted to meet the objections of biologists by constructing a model of a planetary world that was receiving radiation from a star, the output radiation of which was increasing monotonically. In their formulation, the temperature of the planet was set by the balance between incoming and outgoing radation; the latter comprising both re ected and re-radiated energy. If the planetary albedo was held constant, the surface temperature of the planet would rise as the radiative output of the star increased. The expected increase in temperature could be readily calculated using the Stefan Boltzmann relationship between radiation and temperature. Lovelock and Watson then seeded their imaginary planet with daisies of two types: black and white. At lower stellar output the black daisies ourished and decreased the planetary albedo, thus increasing the surface temperature; as the stellar output increased, the white daisies competed successfully. This increased the planetary albedo and the surface

temperature was modulated below the value expected for a lifeless planet. Thus, the presence of these two variants (black or white) of a single species on Daisyworld produced a remarkable stabilization of a global environmental parameter (*see* **Daisyworld**, Volume 2).

Like the original concept of Gaia, the Daisyworld model has produced both interest and controversy. It has been elaborated to accommodate multi-species interactions and it has been demonstrated that some variations of the model are destabilizing. Nonetheless, the original model can be said to have fulfilled its original purpose. It provides an existence theorem that shows that competition between the populations of black and white daisies can produce global environmental stabilization without any teleological presuppositions being built into the model. The problem with Daisyworld is not that the model did not work but that it was so remote from the real world to make its applicability uncertain. The daisies have no physiology or biochemistry, they are simple geometrical black or white discs. And they are introduced into Daisyworld at the will of the modeller. Once again, the problem of evolution appeared to have been evaded. If stability depends upon the daisies having some particular optimum temperature for growth, how is that value achieved? In the model it is inserted by the modeller; whereas in the real world temperature optima are phenotypic characters arrived at by Darwinian selection.

While the specific example had shortcomings, it did prompt scientists to search for similar feedback in the real world. The regulation of the temperature of the real planet Earth, as opposed to the imaginary planet Daisyworld, does in fact provide some possible areas in which to look for supportive evidence for the Gaian idea. One focus of effort was to try to understand the relationship of global biological activity to the well documented ice ages of the past million years (the Pleistocene). Analyses of air bubbles entrapped in ice cores from the Arctic and Antarctic provide important information about the chemistry of the atmosphere during the more recent glacial–interglacial cycles (Lorius *et al.*, 1990). These records indicate that the concentration of the most important greenhouse gas, carbon dioxide, varied in approximate synchrony with the temperature record. From the Gaian perspective, in its most direct sense, it might be suggested that a biotic thermostat should be evident in which the onset of an interglacial–glacial transition (global cooling) would be accompanied by an increased level of carbon dioxide that would offset or ameliorate the fall in temperature. In fact the opposite is evident from the observations; global cooling occurs concomitantly with a decrease of carbon dioxide and, correspondingly, there is an association between global warming and increased carbon dioxide. The precise causes of the changes in carbon dioxide are not understood but such effects appear to suggest a positive feedback rather than the negative feedback that one might expect as a characteristic of Gaia. That is, if the changes in carbon dioxide are driven by biological activity, then the biota are acting to destabilise global temperature such that a relatively minor response to cyclic changes in insulation is thus amplified rather than attenuated. Proponents of the Gaia concept might point to the fact that life persisted through the ice ages (e.g., through the mechanism eventually acting to offset the cooling) or even that the range of temperature variation allowed might have contributed in some way to later sustaining more abundant life (e.g., by usable soil).

Another suggestion of a Gaian connection to the regulation of the surface temperature of Earth is provided by an intriguing relationship between the production of dimethylsulphide (DMS), $(CH_3)_2S$, by marine algae and cloud formation over the open ocean (Charlson *et al.*, 1987) (*see* **Dimethylsul de (DMS)**, Volume 1). Cloud formation is limited by the availability of cloud condensation nuclei. In a marine environment, remote from land, one of the principal sources of such particles arises from the atmospheric oxidation of DMS. DMS is an end product of algal metabolism, predominantly formed when the algae are ingested by zooplankton. Atmospheric oxidation of the DMS occurs principally by reaction with the OH radical (*see* **OH Radical: is the Cleansing Capacity of the Atmosphere Changing?**, Volume 2). The oxidation products, $CH_3SO_3^{\bullet}$ and $SO_4^{2\bullet}$ can act as cloud condensation nuclei. The particles formed in this manner appear to be of more significance in cloud formation than those formed from sea salt. Cloud formation, in turn, can increase global albedo and affect the global radiation budget. Thus, the metabolic activity of marine algae can modulate global surface temperature. Lovelock regards this as an important instantiation (representation by on example) of the kind of processes that one would expect to encounter when looking at Earth from a Gaian perspective. However, to qualify as confirmatory evidence, such processes should be involved in a negative feedback loop. Further, to meet the Darwinian argument, the beneficial effects of such a loop have to outweigh the metabolic costs to the organisms responsible for DMS production. Since Lovelock drew attention to this important climate/biota relationship in 1987, much effort and ingenuity have gone into suggesting how such a feedback might occur but no model has been generally accepted. At the observational level, measurements of $CH_3SO_3^{\bullet}$ in ice cores associate the low temperatures of the last ice age with high $CH_3SO_3^{\bullet}$ and therefore with increased cloud formation. As in the case of carbon dioxide, the activity of the biota appears to have been destabilizing. The decrease in temperature would be more pronounced as the result of both a drawdown of atmospheric carbon dioxide, leading to a reduced greenhouse effect, and an increase in DMS production, leading to an increase in global albedo.

The concept and notion of Gaia is intriguing, it has provoked interesting areas of scientific inquiry and it continues to provoke much debate. As analysis of the Earth as a system continues, the Gaian contribution has been an enhanced recognition of the role of the biosphere. Two effects on biology are likely to persist: a new interest in very large-scale symbioses and a new consciousness of the importance of microbial processes in global ecology. Thus, some acceptance has been given to that part of the Gaian view which sees the functioning of the planetary biosphere as being dominated, today as it has been for 3.5 billion years, by microorganisms (*see* Microbial Diversity, Volume 2).

Is Gaia merely a description (fanciful, useful, or both) of the state of affairs on one particular planet, Earth? Or is *Gaianness*, to use computer jargon, platform-independent? If Lovelock's suggestion that habitation of a planet will always result in an anomalous planetary surface were ever to be substantiated, then Gaia theory would take its place among the major imaginative leaps of scientific thought. One might particularly liken it to the 19th century formulation of the Laws of Thermodynamics, rules that apply to assemblages of matter, independent of structure or location. While further investigation of the Earth will be fruitful in expanding understanding, the search for life elsewhere in the Universe, which was Lovelock's original impetus for development of the concept, will provide its most stringent test.

Gandhi, Mohandas Karamchand

(1869- 1948)

Mohandas Karamchand Gandhi, also known as *The Mahatma* (The Great Souled One), is most famous as the non-violent force behind the independence of India from British rule in 1947. His spiritual stance on the struggle for truth (*satyagraha*) also led him into developing his influential teachings and practices on economics and what would now be called alternative living. The idea of *small is beautiful*, based on the book of the same name by Ernest Schumacher, derives ultimately from Gandhi's example.

Gandhi was born in 1869 in Western India, and as a young man traveled to London to study law. This gave him insights into British culture that were invaluable in later life; for example, well placed letters to *The Times*, or appeals to the British sense of fair play. While in London in the late 1880s, he became caught up in various alternative groups, made up of spiritualists and vegetarians, who were interested in Eastern thought. Ironically, it was these Westerners who awoke Gandhi to the strengths of his own Indian traditions. Gandhi also absorbed the writings of Leo Tolstoy on non-violence, and was particularly influenced by John Ruskin's book, *Unto This Last*, which attacked the classical economists' views of human nature as selfish and competitive. This became hybridized with his own Indian traditions, a mixture of Hinduism and the non-violent religion of Jainism.

As a result, beginning with his career in South Africa as a barrister, Gandhi evolved a sophisticated strategy for pressuring governments and companies to change their policies. This combined exhaustive legal work on the issues at stake with a general mobilization of the affected parties in non-violent protest. Gandhi believed, quite early on, that the main reason for the maltreatment of the Indian communities (and others later on) was that these communities had themselves internalized the vision of their current masters. By non-violent protest, these communities were

empowered, and were morally strengthened by their very refusal to resort to violence. This gave them superiority over their supposed superiors, who inevitably resorted to violence, violence that would in the long run undermine the official claims to legitimacy.

Accompanying this non-violent approach to political conflict, Gandhi further explored the personal and social aspects of the pure in heart, through experiments in simple living in *ashrams*, that is, small communities of believers. These experiments in weaving one's own cloth, cleaning out latrines (seriously threatening in a caste-ridden society where only untouchables were supposed to do this), milking goats, etc., were eventually made part and parcel of Gandhi's politics. He argued that before one could rule the nation (*the raj*) one had to be able to rule oneself (*swaraj*) and that this entailed, among other things, making one's own products, like clothing (*swadeshi*). This was a direct attack on the vast British import/export businesses centered in India.

In the 1930s, as the struggle for Indian independence heated up, Gandhi became world famous, both in prison and out on the march. His contests against the British government mobilized millions of followers in extraordinary scenes of non-violent resistance. Simultaneously, Gandhi's constant effort to understand and develop the implications of the search for spiritual truth, in the personal as well as political spheres made him a beacon for some, and a headache for others. An escalating series of fasts and non-violent protests brought the British government to the reluctant admission that they would have to grant some form of independence to India: a process that was delayed by the onset of World War II. Throughout this period, the political party associated with Gandhi (the Congress Party, headed by a disciple of Gandhi's, Nehru) continued to advocate independence. This was further complicated by the gradual dissolution of a Hindu-Muslim partnership, which would eventually lead to the bitter partition of India into India and Pakistan.

Throughout the run up to Independence (in August 1947) and the rioting and fighting that accompanied it, Gandhi struggled against the tide of violence. He was himself shot by a Hindu militant on January 30, 1948. Near universal mourning ensued.

Gandhi's economic and environmental teachings were immediately repudiated by the new Indian government, which embarked on widespread industrialization and quasi-social central planning. Some of Gandhi's disciples continued to press his teachings and practices subsequently, to marginal effect.

Nevertheless, it can be seen that Gandhian non-violence as a concept and a practice has been one of the most influential weapons in the struggle for justice over the last 50 years. The Reverend Martin Luther King Jr was only one of those for whom Gandhi's model was central. The peaceful revolutions in Eastern Europe, the Philippines, and most recently in Yugoslavia owe much of their inspiration and tactics to Gandhi's spiritual pressure. The core idea, that both sides in any struggle are seeking a truth, which the seemingly weaker side can impress upon the seemingly stronger through its commitment to the justness of its cause in the face of violence, has become widely practiced. Martin Luther King's idea that segregation is a degradation of whites as much as, if not more than, blacks, also derives its moral suasion from a Gandhian vision.

In recent years, Gandhism has maintained its immediate political influence among environmentalists, notably in the mobilization against the Narmada dam, and the Chipko women's movement in Northern India. His writings on self-rule at the village level remain central to participatory models of development. Finally, over the longer term, it is his attempt to lead a spiritually holistic life, where non-violence includes non-violence against the things of the Earth that makes Gandhi a continuing figure to be reckoned with in the environmental movement worldwide.

Governance and International Management

Nazli Choucri
Massachusetts Institute of Technology, Cambridge, MA, USA

In the absence of world government, the matter of global governance assumes particularly important proportions. This is especially true in the environmental domain as human activities generate signi cant problems of global scale and scope. At issue are formalizing modes of moderating con icts and enhancing prospects for cooperation among nations in a context where the proverbial anarchy prevails, modulated by rapid change and increased complexity. Signi cant among these complexities is the variety of actors and agents whose interactions are subject to international management; nation-states, international corporations, non-governmental groups, local actors, and regional agencies are among the most salient of these actors. And, as international rules for collaboration and management consolidate, new actors appear to be emerging with new demands and new propensities for con ict or cooperation as the case might be.

GLOBAL REALITIES

The reality of global politics, and its legal underpinnings or lack thereof, is that only states are enfranchised to act on behalf of individuals. Only states represent populations; only governments represent constituencies with legal standing. Individuals *per se* have, as of yet, no formal mechanism of representation other than the state. While there is evidence of some movement toward recognition of alternative voices in international forums, only the state is recognized as voter.

Therein lies the heart of the dilemma of international management: The state represents a range of demographic constituencies that organize around territorial conglomerations but international problems transcend territoriality and even their mere definition (let alone solutions) cannot be readily mapped over the global arrays of national sovereignty. Moreover, the state is notorious for its porousness (just about everything leaks across national borders) thereby compounding the dual tasks of discharging responsibility and the effective execution of authority.

Challenges to Governance

The essence of the management challenge worldwide is how to reduce the critical disconnects between the demands for coordination and governance, on the one hand, and the supply of legitimate or legitimized mechanisms, on the other – given current realities and evolving complexities.

Modes of Collaboration

Few international realities are as readily discernable and ephemeral, at the same time, than the diversity of collaboration potentials. These range from issue-specific bilateral agreements (formal or informal) to broad ranging, comprehensive global accords (again, formal or informal). In general terms, the logic of international management rests on three key questions, generally known as the *why*, *when* and *how* of global accord:

1. Why collaborate?
2. When to collaborate?
3. How to collaborate?

Of the many conditions that necessitate global accords, two are particularly apt in reflecting the cluster of reasons driving the quest for accord. Countries collaborate (a) in the pursuit of common interests, or (b) in the management of common aversions. In the first instance, states seek collaboration in order to jointly pursue some objective that they might not be able attain individually. In the second, the quest for collaboration is driven by the awareness that they face common adverse conditions that require coordinated action for effective management.

This general logic presumes that countries can identify their specific preferences and objectives, as well as vulnerabilities and sensitivities, and that countries are able to identify the conditions under which unilateral action is not appropriate or bilateral operations will not be effective.

By definition, collaboration involves self-imposed internal or external constraints on national sovereignty. Internal constraints mean refraining from taking actions that have

national consequences. External constraints mean refraining from generating adverse effects outside territorial boundaries. In the environmental domain, broadly defined, as well as in the domain of sustainable development, global accords involve both sets of constraints.

IMPERATIVES OF INTERNATIONAL MANAGEMENT

Underlying the development of modes of international management is the evolution of shared understandings, common formulation of problems at hand, and a joint search for modes of coordinated action. In those terms, the accords themselves are the end product of one type of process; namely that of reaching an agreement. The follow-up requirements involve an entirely new and often complex set of processes at both national and international levels.

The duality, framed in terms of joint pursuit versus common aversion, begs the question of contents, i.e., what is it that is being pursued or needs to be avoided? Who is it that is engaged in avoidance or in pursuit of aversions? What would be the impacts of success or failure (assuming clarity on criteria for each)? How would any of this make a difference? When might this matter most?

Collaboration Imperative

Collaboration becomes an imperative when the problem is recognized, when it is pervasive, and when it eludes unilateral solution and, above all, when no action inevitably means a worsening outcome. These properties are well illustrated in the environment domain characterized by uncertainty, irreversibility, and complexity.

Collaboration becomes a global imperative when:

- *Nature is a player*. This means that environmental effects of human action may take on unanticipated forms, whose uncertainties are suf ciently great as to insert a random element of strong proportions that cannot be contained by human action.
- *Damage is due to legitimate action*. Far from re ecting pathology and deviance, environmental damage is often due to the most normal, routine, and legitimate behavior, whose very nature may be condoned if not lauded worldwide.
- *Force cannot work*. In such contingencies, the deployment of troops, the most conventional instrument of force, is a singularly ineffective, if not a remarkably useless course of action, in that the response is irrelevant to the nature of the challenge.
- *Compliance is imperative*. The pervasiveness of environmental dislocation means that no one can be immune from attack so to speak and that everyone s security is contingent on compliance by everyone else.
- *Doing damage by doing nothing*. Simply by choosing not to take a stand, nations can accentuate prevailing environmental problems; thus, the costs of not participating in evolving environmental accords will be equivalent to overt opposition.

Once collaboration takes place in an institutionalized context, one might ask: why does institutionalization happen?

Institutional Necessity

To simplify, the conventional understanding is that institutionalization at the global level takes place in order to: (a) consolidate and pursue new norms; and (b) coerce states that resist the new norms, and pressure states breaking norms into conformity with the collective understanding; (c) reduce uncertainty in process, outcomes, and information; and in some cases (d) generate and maintain shared modes of communication, understandings, and explanations. Finally, institutionalization is believed to (e) facilitate mediation among con icting actors, and (f) enhance overall prospects for problem solving. All of the above is contingent on some minimum degree of shared understanding of the challenges at issue, in combination with the dual principles of participation and representation in a world based on the principle of national sovereignty.

Key Trends

In this connection, three trends have contributed to the increasing importance of international environmental management. The rst pertains to the increasing role of scientists in shaping the policy agenda. By drawing attention to environmental dislocations due to human activity, by voicing views expressed by a critical mass of scientists playing an important catalytic role by pressing for political recognition of the problems at hand, they exert pressure at national and international levels for policy response. The second trend relates to matters of trial and error, precedent, and renewed efforts in the domain of environmental policy formulation and coordination. The international community has gradually developed a set of principles that reinforce the fabric of international environmental agreements. These include the *precautionary principle* and the *polluter pays principle*, among others. The third trend is the increasing attention at the national and international levels to matters of capacity building for environmental management as well as increased investments in national environmental reporting.

MODES OF INTERNATIONAL MANAGEMENT

In the domain of environmental management and sustainable development, the spectrum of management

modes ranges from formal agreements with legally binding commitments (i.e., the conventions) to informal agreements and soft law (like Agenda 21), on the one hand, and a set of varied instrumentalities and modalities, on the other. These patterns (framed in Table 1 below) are incorporated in the knowledge-based global networking system entitled, the *Global System for Sustainable Development* (GSSD). Used for examining the implications of global accords at local, national, and international levels, GSSD is currently operating in multiple languages and in different parts of the world.

While items (1) and (2) in Table 1 are those most commonly mentioned when referring to global accords, it is often useful to consider that these modalities are often supported by a combination of modes (3)–(14) as relevant. Conceived as legally binding international commitments, the Conventions represent the strongest form of accord and require the most intrusive forms of institutional supports. This latter consideration is due to the fact that formal commitment entails a corollary commitment to put in place enabling mechanisms: nationally or internationally, as the case may be. This corollary is in the nature of an insurance policy.

To reduce potentials for non-compliance due to capacity constraints (i.e., countries may be unable as opposed to being unwilling to comply) a range of capacity building measures increasingly accompanies formal commitments. This is especially the case in the domain of environment and sustainable development. Many of these measures are in the nature of institutional innovations, which can often impinge on traditional conceptions of sovereignty.

INTERNATIONAL RESPONSES AND INSTITUTIONAL INNOVATIONS

When environmental issues are rooted at the local level and travel to the global commons, when individual actions generate global dysfunctionalities, and when states are unable to manage their own environmental agenda, then national governments and their instruments are placed in a precarious position. On the one hand is the situation discussed below (within state borders) that often eludes governmental management. On the other hand are cases where competing sovereignties (each subject to similar elusiveness) seek common principles and modalities of convergence.

Evolving Modalities

Given that states remain the only voters in global forums, nonetheless, there has been a discernable move toward expanded forms of international management involving both participation and representation of non-state actors.

Table 1 Modes of governance and international management as represented in the Global System for Sustainable Development (GSSD)

(1) *Agenda 21*
(2) *Formal conventions, spanning a range of general and comprehensive issues, as:*
- Atmospheric
- Hazardous wastes
- Marine environment
- Terrestrial resources
- Freshwater resources
- Nuclear, safety, and related technology
- Others

(3) *New development and investment mechanisms*
- Cleaner development mechanism (CDM)
- Joint implementation
- Activities implemented jointly
- Innovative investment system

(4) *Technology agreements, such as:*
- Technology transfer
- Training and implementation

(5) *Monitoring performance*
- Limits on hazardous activities
- Benchmarking systems
- Compliance records

(6) *Codes of conduct and voluntary agreements*
(7) *Financial and investment codes*
- Environmental conduct
- Voluntary agreements
- Human rights issues
- Other

(8) *Conflict management and peace strategies*
- Dispute resolution
- Peace keeping
- Conflict prevention
- Other

(9) *Population management*
- Population policies
- International migration strategies
- Resettlement initiatives
- Other

(10) *Economic adjustments and agreements*
(11) *Trade regimes and agreements*
(12) *Environment agreements*
(13) *Corporate responses*
- Organizations
- Agreements
- Private-public partnerships
- Social responsibility

(14) *Strategies of international institutions*

Source: http://gssd.mit.edu.

This move is driven by the realization that environment and sustainability are characterized by rather novel properties distinguishing this realm of evolving international law from other domains of international interaction. For example, the United Nations Framework Convention on Climate Change (UNFCCC), the Kyoto Protocol and the follow-up

measures, all targeted specifically to environmental factors, serve to illustrate the institutional innovations as well as the attendant disconnects (*see* United Nations Framework Convention on Climate Change and Kyoto Protocol, Volume 4).

Among the distinctive features is the framework strategy, rather than precise commitments; process orientation coupled with target specifications; provision for internal as well as international institutional supports; and commitment to long-term adjustment processes based on expectations of innovations in policy instruments.

Less formal than the UNFCCC process, but no less pervasive, is the Agenda 21 process; including the formulation of the contents of Agenda 21, and institutionalization of the follow-up mechanisms via the United Nations Commission on Sustainable Development. Central to these novelties is the tendency for various interests and interest groups to organize networks of communication that eventually become networks of influence. As a result, the increased use of observer status in international forums, combined with the provision of space and the allocation of time for various non-governmental groups to convene during the formal negotiation processes has given non-state actors new venues for voicing their concerns, if not their demands. While none of these innovations alters the fundamental constitution of global politics and none of this transforms the basic sovereignty of the state, it does render the state more transparent and its formal actions subject to greater scrutiny.

These processes are designed to accommodate non-state actors and interests only to the extent that these can be incorporated within the formal structures of deliberation among sovereign entities. But the consolidation of these new institutional processes invariably serves as conduits through which the demands of local constituencies can be reflected in global forums. Invariably, also, they point to the fundamental disconnect, for example, that the mayors of mega cities are not (and cannot be) at the negotiation table nor is there any legal provision for their presence. However, they now have access to transmission mechanisms that may ensure that their views may make their way through the global policy formulation process.

Transcending or Incorporating the State?

What happens next if the views do make their way through the formulation process? In essence the same challenges of disconnect remain. If, and only if, the national government is willing (or agrees) to engage in a dialogue with the mega city institutions (or mayors), can authority devolve from the state to sub-national units and to extra-territorial institutions? Both instances reshape the responsibilities of the state and the scope of its leverages.

In the absence of any serious potential for redesigning the global state system, the most plausible approach might involve rendering more robust some of the existing instrumentalities. Among these are: (a) international pressures on national government to formally account for urban representation in global forums (as part of the national delegation or in nongovernmental contexts); (b) formal arrangements among sub-national governments (such as mayors or functional equivalents) to represent their own interests directly in global forums (as nongovernmental agencies); (c) organized interest articulation of sub-state (or trans-state) representatives to obtain new incentives from national institutions or international institutions, (d) potentials for direct negotiation on projects that arise in the context of CDM (cleaner development mechanism) discussions, and other.

As an example, much of the deliberations and reporting of outcomes for UNFCCC – 5th Conference of Parties (COP/5), has stressed two major venues of deliberation – the state centered forums and the non-governmental organization (NGO) based deliberations. However, even when diversity of interests is evoked, it is almost always with reference to diversity of interests across states. The disconnects at hand pertain to the global implications of sub-national interests and of their potential disjunction with national interests. The data requirements (within the context of national reporting as well as the Intergovernmental Panel on Climate Change (IPCC)) are nationally defined, sectorally formatted, and activity framed (as observations permit).

In addition, we can discern the foundations for four new venues, any one of which might have some merit, but altogether, they may create significant next steps in the question for viable modes of international management. These can be characterized as: (a) consolidation of cross-national political networks supporting collaboration; (b) combining resources for generating and marshalling needed knowledge buttressing the demands for collaboration; (c) maintaining a sustained presence in international forums to influence the evolution of accommodation to non-state actors; and (d) exerting organized and mounting pressures on national representatives toward greater international management.

Many of these developments are converging around the notions of civil international society and of civic global responsibility, where both qualifier c terms reflect a new recognition of non-state agencies, and the potential legitimization of the international civil (in contrast to state centered) society.

Finally, it is important that such venues may contribute significantly to the consolidation of the two critical conditions for effective management, at any level, local or global. These are: (a) viable and relevant modes of representation; and (b) effective and standardized mechanisms for participation. The international community is in the

midst of a grand experiment, namely developing modes of international governance and global management in a still largely sovereign centered world, without imposing formal government and institutions of governance that mirror those of the state system.

Hazards in Global Environmental Change

Kenneth Hewitt
Wilfrid Laurier University, Waterloo, Canada

*The prospect of disasters related to, or magni ed by, global environmental change is increasingly debated. The problem arises in at least four ways: (i) Dangerous trends: environmental damage or transformations themselves threaten extreme harm; for example, ozone-layer depletion, bioconcentration of toxic contaminants or the emergence of drug-resistant epidemic diseases. (ii) Magni ed risks: there may be increases in the incidence and scale of disasters associated with age-old threats such as droughts, re or pests. Examples include the role of deforestation in oods and wild res, and of climate change in weather hazards or an expanded range of insect-borne epidemic disease (*see ***Natural Hazards***, *Volume 3). (iii) Novel threats: new or magni ed disasters may arise from the development and deployment of technological innovations, or from deliberate environmental modi cations and megaprojects. Some identify such risks with, for example, the introduction or escape of genetically engineered organisms into the biosphere, very large water and power schemes, or ocean oor mining.*

(iv) Increasing social vulnerability and adaptive capacities. This class of problem is related to the fact: that the occurrence and form of a disaster always depends both upon dangerous conditions and the state of human communities exposed to them: increasing social vulnerability and adaptive capacities. The likelihood and impacts of disasters are transformed by demographic, organizational, work and life style changes - even in relation to environmental hazards that do not themselves change in severity or incidence. Endangerment arises with urbanization, transformations in industry, agriculture, transportation, and leisure activities worldwide. Only where public safety measures keep pace, will dangers be kept in check.

Modern innovations and organized responses also counteract such dangers. Research, forecasting, standards, protections, insurance and other safety nets, have dramatically improved public security or the ability to survive damaging events - in some places. Societal vulnerability and adaptability apply, of course, in all four of these disaster contexts. And they involve another issue of global change: changing approaches to disasters. In addition to new disasters and changing risks, there are emerging constituencies, technologies, agencies and agendas relating to disasters. They demand or promote re nements in understanding, or a recasting of the problem. A strong impetus comes from changing expectations of, and dif culties for, national or international emergency preparedness, for humanitarian assistance and activism by, or on behalf of, disaster victims (IFRCRCS, 1998).

Most disaster-related investigations still focus upon environmental and technological agents that may cause harm, whether floods and earthquakes, oil spills, or viral diseases. There is a continual flow of new findings and refinements regarding these hazards. Few will question the importance of such knowledge for risk assessments in a changing world. Nevertheless, the importance of social or cultural understanding, and the dangers of neglecting it, are increasingly recognized (Hewitt, 1983; Blaikie *et al.*, 1994; Quarantelli, 1998; Enarson and Morrow, 1998; Oliver-Smith and Hoffman, 1999).

To grasp the meaning and impetus of these concerns, we must consider their relation to entrenched and contested views of the disaster problem. Most of us may feel we know a disaster when we see one. Yet, like any other general problem – development, poverty, war, ruined habitats – it is much harder to find a widely agreed characterization of disaster, adequate for scientific and humanitarian purposes. Approaches tend to split, firstly, between those preoccupied with what is unique about disasters, and those that link them to broader conditions of environment and society.

DISASTER IN AND OF ITSELF

Disaster or calamity identi es a primary form of experience; a condition of great fear, life-threatening harm and loss. There is also a sense of something untoward, violent, tragic. Everyone dies, but mass deaths by re or ood, in a plane crash, an avalanche, a famine or terrorist attack, seem specially terrible misfortunes. There is not just untimely death and thwarted life. The capacities a person might otherwise have to escape or survive are overwhelmed as in a nightmare. There is the agony of abandonment by, or being unable to protect, loved ones. Also conveyed is the sense of singular occasions or historic(al) turning points (Elliot, 1972; Scarry, 1985).

At their worst, there is little to distinguish the disasters of war, famine, natural and technological catastrophe or pandemic disease. People have always lumped them, or their imageries, together: ruined homes, uprooted families, hungry, exhausted and desperate folk eeing the devastation or huddled in makeshift shelters, the injured and the heaped up dead. Most disasters share this common and dreadful content (Sorokin, 1942). Hence, it is argued they are, above all, humanitarian problems demanding all reasonable efforts to prevent or mitigate them, especially where human-induced changes threaten to make them worse.

Some technical or of cial de nitions also accept and characterize disasters as distinctive and special problems, though they distance themselves from victims feelings and startling imagery. A recent, clear example de nes disasters as:

> ••• non-routine events in societies or their larger subsystems (e.g., regions, communities) that involve social disruption and physical harm. Among the key de ning properties of such events are (1) length of forewarning, (2) magnitude of impact, (3) scope of impact, and (4) duration of impact.
>
> (Kreps, 1995)

Establishing dimensions that seem to bracket disasters as extreme events, and separate them from other times and places, has been a concern of contributing disciplines. There is a preference for impersonal dimensions or mechanisms, in contrast to the experiential or vernacular views, described earlier:

> ••• a state/condition destabilizing the social system that manifests itself in a malfunctioning or disruption of connections and communications between its elements or social units; partial or total destruction/demolition; physical and psychological overloads suffered by some of these elements •••
>
> (Por riev, 1998)

Modern ideas de ne disasters, especially, in relation to, and as the opposite of, predictable, normal, and stable conditions. However, there are other professionals who reject or strongly qualify the idea of disaster as a unique or separate problem. Rather, they see disasters as endemic to, or symptomatic of, the social systems in which they occur (Morren, 1983).

DISASTER MYTHS AND THE PRINCIPLE OF CONTINUITY

Extraordinary terror, trauma, destruction and death surely occur in disasters. Few can argue against paying special attention to them and the worst hit areas. However, comparative and general studies reveal a very different balance of conditions. In most events, most property and persons within a designated disaster areas, are only slightly harmed, or unscathed physically. Even where they are in small numbers, survivors who are not completely disabled, usually carry out most or all of the primary life-saving and harm-reducing activity. In the crucial hours or days before outside help arrives, if it arrives, they rescue those who would, otherwise, be lost. Much, or most emergency relief, food and shelter, is provided by households within or near the devastated areas.

However, popular or media images not only focus on the more or less heroic rescue efforts of outside agencies, the armed forces, international relief and modern technologies. They also portray the disaster in terms of wall to wall devastation, chaos and panic; or concentrate on the more pathetic and prostrate victims, anti-social behavior such as looting, and lucky or miraculous survivals (Ploughman, 1995). Disaster research has shown that these are usually exceptional cases, or re ect mistaken assumptions, stereotypes and selective reportage. Instead, most survivors act, as far as is humanly possible, in terms of the concerns and responsibilities they had before, whether in families and the community, their institutional position or professional skills. This suggests the need for what Quarantelli and Dynes (1977) call a principle of continuity with, rather than a radical separation of disaster from, preexisting societal conditions and normal human responses.

If so, how and how far preexisting conditions and resources in uence peoples responses to disaster are important questions. These, no less than the severity of ood or re, decide the capacities of those at risk to survive and cope. In turn, this suggests that the key questions of global change are how it alters people s vulnerability; and how it erodes or bolsters their adaptive capacities.

INTERPRETATIONS OF CALAMITY

In the broadest terms, explanations of disaster involve four sets of factors:

1. Dangerous agents or hazards, such as earthquake or re, viruses or toxic chemicals, equipment failure or collisions, that initiate the destructive event, or cause most of the damage.

2. Vulnerability of exposed persons, property or activities to dangerous conditions, (discussed in detail below).
3. Risk-reducing and disaster-mitigating measures, which may be directed at particular hazards, or vulnerabilities, and include organized emergency preparedness.
4. Contexts and intervening conditions, factors that indirectly, but sometimes decisively, influence the above three. For example, changes in vegetation cover by forest industries or clearance for agriculture affect flood-generating runoff. Population density, health and well-being which will change due to economic development or urbanization, alter risks of epidemic disease. Technological innovations increase risks though directed at, say, productivity or consumer demand. Such conditions intervene between dangerous forces and vulnerable people to modify their interactions, whether for good or ill, but arise or vary independently. Global change is as likely to affect risk through a range of societal and habitat transformations, as in directly altering flood hazards, safety equipment or high risk technologies.

Actual disasters involve all four sets of factors, but most disaster studies and related activities focus on just one of them. An agent-specific or hazards perspective remains the prevailing perspective. Moreover, this encourages a view of disasters as originating outside, or beyond social control:

> ••• Disaster means the impinging upon a structured community of an external force capable of destroying human life or its resources for survival, on a scale dire enough to excite public alarm, to disrupt normal patterns of behavior •••
>
> (Lemons, 1957)

With respect to technological and social hazards, this idea of disaster converges with that of the accident (Green, 1997) in which danger is not merely identified with unforeseen and unwanted occurrences, or human error, but a domain of uncertainty:

> ••• were there perfectly accurate predictions of what would occur and when it would occur in the intricate web of atmospheric, hydrological and biological systems, there would be no hazard •••
>
> (White, 1974)

This view of disasters as uncertain, unscheduled or accidental events, serves to detach them from preexisting conditions, and the control of on-going social life, and place them in a realm of extreme and rare natural or technological processes. The only possible social responses are then seen as specialized technical efforts to model and counteract such extreme forces and events (Hewitt, 1983).

There is a radical contrast, once again, with interpretations in terms of conditions of everyday life:

> ••• Disaster is the actualization of social vulnerability ••• we interpret the notion of social vulnerability as an independent factor (predictor) of risk •••
>
> (Carlo Pelanda, 1981)

Here, danger is seen to arise from styles of settlement and land use, occupations, technological innovations, wealth and political influence. To accept this means that disaster reduction and emergency preparedness would have to focus much more on the risks embedded in existing social systems, and on global changes that alter peoples' exposure, capacities and everyday developments.

SOCIALLY DISCRIMINATE OR INDISCRIMINATE EVENTS?

The external force/extreme event view also tends to accept that death and loss in disasters are a function of the type, intensity and distribution of the damaging agent, but socially indiscriminate – affecting old and young, rich and poor, men and women at random and, in effect, equally. The opposing view emphasizes the evidence that who lives and dies, the scale and severity of losses, are strongly prefigured in the social order. They clearly identify certain persons or groups, places or activities, as much more vulnerable. Again, this directs us to conditions and developments in society. Social vulnerability, and adaptive capacities must be examined, and the roles of cultural and environmental contexts. The result is a view of the origins of disaster that departs more or less strongly from mainstream, agent-specific investigations that emphasize exceptional or disaster-specific responses.

VULNERABILITY OR THE HUMAN ECOLOGY OF ENDANGERMENT

A vulnerability perspective considers especially how communities are exposed to dangers, the ways in which they are readily harmed, and the protections that they lack. When disasters do occur, it directs attention to peoples' capacities to withstand, cope with, mitigate and recover from damages. It examines whether, or how well, they are served by organized relief and rehabilitation measures (Table 1).

Here, the problem of disaster is seen to depend primarily upon on-going societal conditions or developments. It depends upon many aspects of society that, by design or default, can decrease or exaggerate the impact of damaging agents. However, if particular forms of vulnerability relate to particular hazards, peoples' vulnerability can arise more or less independently of where flood, storm, epidemic disease or explosion may occur, and their severity. Vulnerability is largely created within, distributed or offset by, the social order. It depends upon how society treats people according to their age, class, or religion; on gender and

Table 1 The main forms and conditions of vulnerability (after Hewitt, 1997, 144)

1. Exposure to dangerous agents or conditions through occupation, location near a dangerous facility, lifestyle
2. Physical weakness or susceptibility through predisposition, age, disability, impairment of persons, poor design of buildings, insecure practices
3. Disadvantage, or structural weakness involving lack of resources, capabilities or access to facilities, often identified with poverty, dependency, exploitation and social injustice
4. Defenselessness or lack of protection to counter weaknesses, to prevent or avoid dangerous situations, emphasizing protection otherwise available in the society concerned
5. Lack of resilience or capacities, where the means and ability to respond are limited and impaired, options are not recognized, and readiness for creative responses missing
6. Powerlessness, an inability to gain access to, or influence safety arrangements; exclusion from and inability to get the attention of the relevant and influential social agencies

other divisions of labor; on cultural values and legal rights (O'Riordan, 1986; Enarson and Morrow, 1998).

Of course, everyone is vulnerable, at least in an absolute or worst case sense. Some persons, activities or places may be vulnerable because neither they nor anyone else has the means to make them safer. Moreover, people in all situations can, and usually do, accept some risks.

Yet, a majority of those who actually suffer harm and loss in most disasters are found to be vulnerable in ways that some, if not most, members of their own, or other societies, are not. The homes which collapse in earthquake are not merely structurally unsafe and badly sited, but usually house people disadvantaged in cultural and economic ways (Blaikie *et al.*, 1994). In almost all famines, it is the already hungry or malnourished, who suffer starvation and death (Sen, 1981). Many if not most refugees have been displaced after long-term struggles with livelihood insecurity or coercive treatment (Zwi and Ugalde, 1991). Some people seem driven into, or trapped by, vulnerability syndrome. Rather than a single weakness or category, they are victimized by a whole social context (Wisner, 1993). However, even in less severe cases, vulnerability is a relative condition, and can only be defined and assessed in relation to the safety which others actually enjoy.

HUMAN ADAPTABILITY

Although vulnerability mainly suggests weakness and absent protections, studies of it find that people's active capabilities or resilience in relation to dangers, are at least as important. Only the most impaired or injured are not, in some measure, active agents in their own survival, if not in larger community needs.

There is no form of vulnerability which some or all societies do not deliberately work to reduce and offset. Social safety nets, defenses, insurance, and emergency preparedness can and do mitigate harm. They reduce and offset weakness, or offer protections for the specially vulnerable, for children, the elderly or disabled.

Direct and longer-term involvement with communities at risk, shows how survival turns upon community values and arrangements (Watts, 1983; Vaughan, 1996). Adaptive and coping capacities are also embedded in on-going activity. Patterns of everyday living prefigure and constrain the readiness, capacities, resources and values that will apply in a crisis. Resourcefulness and creative responses may be seriously undermined where social conditions promote submissiveness and dependency, or where individuals, groups and communities find their autonomy constantly opposed and suppressed by the interests of powerful others. Indeed, people who are relatively more endangered, less well-provided with protections and lacking in adaptive capacities, are typically found to be politically weak as well. Defenselessness most often reflects powerlessness (O'Riordan, 1986; Watts and Bohle, 1993). The victims of natural and technological disasters have often, already, been victimized by an unjust, exploitative or coercive social order (Corradi *et al.*, 1992; Kroll-Smith, 1995).

In these views too, the forms of vulnerability and adaptive behavior are not taken as peculiar to what happens during an earthquake or fire. Rather, they direct us to domestic and local spaces of risk, and everyday behavior and conditions. However, as global change studies show, everyday life is nowadays subject to unprecedented changes and risks.

SOCIAL RISK AND DISASTERS IN A TECHNOCRATIC AGE

Today, vulnerability and its changing forms relate, increasingly, to the emergence and reach of late modern society and its institutions. The geographies and contexts of risk relate mainly to whether people live within or outside such societies, and the degree of their access to, or exclusion from, modern safety and security measures.

In the wealthier, late modern countries and enclaves, permanent arrangements, infrastructures and organizations play an overwhelming role in vulnerability, and in the origins of, as well as responses to, disaster. This applies, in particular, to routine public safety and everyday, widely dispersed or chronic dangers. They include institutionalized arrangements to deal with traffic accidents, household fires, illnesses of childhood or the elderly, crime or product safety. These have become the special responsibility of

government, private or non-governmental organizations, oversight agencies or service industries. They involve the largest expenditures on public safety.

Vast sums of private and public money are allocated to insurance and welfare; to health, policing and the courts; to fire fighting, transportation or product safety; to the armed forces, factory or mines inspections, and so on. Whole disciplines and professions have developed to research and carry out these functions, or to train staff for the relevant organizations.

Although, by definition, disasters overwhelm routine arrangements, in modern societies responses are largely dependent upon large, complex organizations, albeit from outside the disaster zone. Such organizations, as Perrow (1995) expresses it, •••have in effect absorbed society . Moreover, the permanent large organizations dealing with chronic dangers, play decisive roles both in limiting and in responding to disasters. In most countries this applies, especially, to the role of the armed forces. Meanwhile, large organizations, their policies, priorities and performance substantially determine each person's safety or vulnerability. Nearly all jobs are in large public and private organizations, and a person's job and status in them, is the main determinant of exposure to, and protection from, risks.

On the other hand, to a growing extent, disasters arise from the fallibility, excesses, or deliberate actions, of these organizations. This is so for many of the graver dangers identified with global change: accidents that arise within or from complex, high-risk organizations. Examples include the Three-Mile Island and Chernobyl nuclear disasters, Bhopal, and the Exxon Valdez oil spill (Sagan, 1993).

The German sociologist Beck (1992) has identified such predicaments with what he calls the risk society. He believes we now confront a new modernity in which the manufacture of risks, or technoscientific accidents, increasingly overshadows productive and progressive forces. He sees people's risk positions, essentially another way of describing vulnerability, as related not just to hazardous processes but to work, food, a place to live, even their leisure choices. Yet, these positions are embedded in, and change with, the more or less extensive risk-producing, risk-averting and risk-redistributing strategies of modern institutions. In relation to global change, he describes the epochal problem of the risk society in this way:

> ••• As nature becomes permeated by industrialization and as tradition is dissolved, new types of incalculability emerge ••• [specifically] ••• the production of risks is the consequence of scientific and political efforts to control or minimize them.
>
> (Beck, 1998)

Meanwhile, social risk positions and the geography of disasters have been transformed according to access to, or exclusion from, the benefits of modern safety arrangements and large organizations. There can be sharp variations in vulnerability within cities and countries, even between members of the same family or neighborhood (Enarson and Morrow, 1998). Disasters, or possible responses, in different regions of the earth, depend upon developments and connections involving those same large organizations. At least, they are involved in massive humanitarian relief efforts in areas remote from cities and industrial development. Meanwhile, the world social space of vulnerability is increasingly a direct or indirect consequence of conditions related to national or global economic, technological, environmental and political influences (Blaikie *et al.*, 1994; Oliver-Smith and Hoffman, 1999).

KNOWLEDGE WORKERS

This condition also places the problem of knowledge center stage. Mainly through the role of large organizations, computerized and centralized controls, thought and action are increasingly in the hands of, or dependent upon, knowledge workers – most of whom are not teachers, academics or intellectuals! They are persons in public and private organizations who work with and through formal systems of information gathering, assessment and communication. They rely upon training in, and facility with, standard technical practices. Even those called practitioners – ambulance dispatchers, traffic policemen, volunteers in public charities – spend much of their time writing things down, exchanging and reading what (official or non-official) others communicate, developing or reading other people's web pages, analyzing and assessing data or undergoing training in such matters. Knowledge workers include virtually all the people who help to generate plans, consultants and inspectors' reports, write field manuals, sit in committees or dispense orders.

To be sure, there are still huge numbers of people, worldwide, whose work is largely manual, whether producing food or raising children, who do not, or cannot participate in the textual and computer literate world of modern knowledge. But ever fewer of them act independent of some technology, procedures and goals, designed and monitored by the knowledge workers. All of this is also part of large organizations and extends their roles.

However, disaster is one of those problems – others are violence, madness, poverty in a world of plenty, crime, addiction, abuse or dropping out – that are specially intractable for, and uniquely threatening to, the rationalized, systematized social order of large institutions (Hewitt, 1983; Burchell *et al.*, 1991). Indeed, part of the current debate concerns how far our approaches to disaster, and their failings, reflect the preoccupations of technocratic organization more than the objective dangers or the predicaments of those at risk (Ericson and Haggerty, 1997).

WHOSE DISASTERS? THE REVERSAL OF EXPERTISE

The contrast between the experience or witnessing of disaster, and technical knowledge work, is not merely one of time and place, but of differing concerns and perspectives. If this seems obvious, it is often ignored in technical disaster work. This not only tends to treat issues from a distance, abstractly and in terms of governmental or other centrally organized responses. It is well known that large organizations can be quite insensitive to, or unaware of, the concerns not merely of vulnerable communities and those trying to cope with and recover from catastrophe, but of other organizations (Turner, 1978). Part of the problem for responsible agencies and professionals, is the extent to which knowledge and understanding of vulnerability and disaster involve a rethink of their normal ideas.

It is not only that suffering and witnessing extraordinary violence justify the oft-quoted feeling of survivors that anyone who was not there could not possibly know or understand. In addition, to the extent that disaster depends upon personal and societal vulnerability or resilience, then it becomes a matter of grasping the circumstances, needs and concerns of those at risk. Vulnerability is always closely bound up with where people live, their work and specific relations to habitat and the larger society, their values and expectations. The idea that someone from outside, however sophisticated in, say, flood hydrology, engineering safety or radiation ecology, can recognize and give a balanced assessment of risks and needs, is socially absurd – especially when there is also an inability to speak the language of those at risk, or being new to the culture, group, and habitat involved. Such is often the plight of the visiting expert; an urbanite speaking to rural peasants, a well-off person trying to understand those living in abject poverty, a survey team of men where women are the most vulnerable, or play a decisive role in family safety.

Without doubt there are things the expert is uniquely able to say and do. The impacts of modern technologies, practices and organizations reach into every corner of the earth, if they do not aggravate or cause the disasters that occur. Experts have privileged opportunities to represent the vulnerable to the powers that be, and *vice versa*. Since large organizations control important resources and actions, it matters how the professionals state the case.

But social understanding requires listening to and recognizing the cultural and psychosocial condition of those at risk. Again, a vulnerability perspective directs us to their situation and predicaments, rather than just impersonal dimensions, processes and organizational procedures. Or rather, it confronts us with the problem of translating between technical understanding into what are variously termed local, gendered, vernacular and indigenous languages or knowledge (Becker, 1991).

CONCLUDING REMARKS

To summarize, social vulnerability and adaptability depend, in large measure, upon on-going material and social life – or their transformations. For that reason, they are surely of decisive importance for the growing concern over sustainable human communities and habitat relations. To adapt to global changes in a sustainable way is, above all, to avoid disastrous collapses. It requires that developments should not put people and property on a collision course with great hazards, or make them less able to withstand or cope with existing risks. It suggests that technological innovations or projects, even consumer goods, that may carry high risks should be subject to exceptional constraints.

Hinduism and the Environment

O P Dwivedi
University of Guelph, Guelph, Canada

The Hindu religion offers a challenging perspective on the subjects of respect for nature (including the principle of the sanctity of all life on this planet and elsewhere) and environmental conservation. In Hinduism, human beings are not given any absolute dominion over their own lives or over the life of any non-human being; only the Supreme God has absolute sovereignty over all creatures, including humanity s life and death. The sacredness of God s creation requires that no damage be in icted on other species without adequate justification. People are not supposed to act as viceroys of God over the earth; nor should they assign degrees of relative worth to other species. All life forms (human and non-human alike) are of equal value and all

have the same right to existence, but only humans have special obligations to care for the environment. In addition, only humans, unlike any other species, are obliged to live in harmony with nature by exercising control over their cravings and obsessions, mainly because they have the God-given capability of free will.

THE VEDIC HERITAGE

Hinduism is the name given to the most widespread religion on the Indian subcontinent. It has had a long history, extending back at least to the arrival of what are now thought to be Indo–Iranian tribes in northern India about 2000 before the common era (BCE) – considered the Vedic period – whose beliefs were mingled with, or layered over, the original indigenous religions in the region. Concerning the dates of the Vedic period, there remain differences of opinion among some Western Indologists and Indian scholars. For example, Griffith (1889) mentions that the Vedic period occurred between 1500 and 1400 BCE, while Indian scholars such as Tilak (1936) and Kane (1966) suggest about 5000–4000 BCE. Perhaps a more realistic date could be about 2000 BCE, see Kak (1994). After the literature associated with the Vedic period (known as the Vedas), there appeared the later Upanishads (addenda to the Vedas, and considered to be datable around 600 BCE, (see Hume, 1977, 6 and Deussen, 1980), and an array of stories and epic poems like the Ramayana and the Mahabharata, that together generated the vast diversity of greater and lesser gods, personal and public rituals, and all the elements that populate today's Hinduism.

The ancient Hindu literature is divided into the Shrutis and Smritis. Shrutis denote the entire body of sacred Vedic Scriptures, which are considered to include the four Vedas, the Upanishads, and some other related texts. Smritis are a number of other Hindu sacred Scriptures created after the Shrutis, including the Ramayana and the Mahabharata, the Dharma-shastras (religious books on Hindu law and behavior), and the Puranas (18 books on Hindu mythologies).

The relationship between human beings and nature attracted the seers of the early Vedic period who contemplated the mysteries of the Creation, the place of heaven and earth, and even beyond. Those Vedic seers would not accept as final what they saw around themselves; instead they asked many penetrating questions, not only about life but also about death and destruction. They were equally interested in the mystery of Creation and the establishment of this universe. Through their deep thinking, guesses, conjectures and postulations, they came to acknowledge that the material causes of this creation happened to be the Panch Mahabhutas (Five Great Elements): earth/Prithivi, air/vayu, space/akash, waters/Apah, light–fire/Agni (Aitareya Upanishad, Chapter III, Verse 3).

These five Mahabhutas are cosmic elements that create, nurture, and sustain all forms of life, and after death or decay, they absorb what was created earlier; thus they play an important role in preserving and sustaining the environment (Dwivedi, 1997a). It should be noted that these Mahabhutas have been deified in the Vedic, and also later in the Puranic literature (starting from 300 BCE to 900 CE). Further, they, all together, are regarded as all-pervasive and omnipresent elements having great creative potency; in addition, they together constitute Brahman (the Almighty God, the all-pervading One, the Supreme Godhead) who manifested the universe and whose manifestation goes on forever. As mentioned in the Shvetashvatara Upanishad:

> The Brahman by whom this entire universe is engulfed. ••• this creation is governed by Him as well as the five great elements: earth, air, space, water, and light.
>
> (Shvetashvatara Upanishad, Chapter 6, Verse 2)

Prithivi (Earth)

The Rig Veda describes Prithivi as a divinity as well as one of the Mahabhuta elements. She is the mother and upholder of all (Rig Veda, Book X, Hymn 18, Verse 10; and Book 1, Hymn 155, Verse 2). Prithivi is also identified with the goddess Aditi: a mother and protector of the holy cosmic law; she is also regarded as a divine ship, full of life-sustaining harvest. She, along with the four other Mahabhutas, sustains our universe. This relationship between earth and humans is superbly depicted by Rishi Atharva (a rishi is a priest/seer), in the Prithivi Sukta (Hymn to Mother Earth) of the early Atharva Veda. (A Sukta is a short composition of verses which relate to a specific subject under discussion. Each Veda consists of several Suktas). This hymn exemplifies the relevance of environmental sustenance and biodiversity to human beings (Satvalekar, 1958). It consists of several prayers including one that promotes the concept of Vasudhaiv Kutumbkam, or the family of Mother Earth (Dwivedi, 1998).

Vayu (Air)

Vayu is the bond and the thread that keeps the universe together. Vayu is also praised like Prana (the life-sustaining breath) – it is the germ of the world and a transformer of seed; without Prana, nothing survives.

Akash (Space)

The term Akash denotes space rather than sky or ether as mentioned in some translated Vedic literature. It is not a material or physical element. In Chhandogya Upanishad, a discussion takes place among Rishis; they finally agree that it is the Akash (space) out of which all beings

(their souls) come, and it is where they go back after their death; thus, the Akash is the final resting place of all beings (Chhandogya Upanishad, Book I, 9th Part, Verse 1).

Apah (Water)

According to the Vedas, water was the first of the cosmic elements. The Rig Veda says that in the beginning, all was water, and there was darkness which engulfed it (Rig Veda, Book X, Hymn 129, Verse 3). Further, the Rig Vedic Hymn 23 (Book I, Verses 16–21) considers water to be the reservoir of all curative medicines and of nectar. Waters are the mothers of all beings, and they are the foundations of all in the universe (Lal, 1995, 9). The genesis of the Universe takes place in the primeval water. The following verse from the Atharva Veda (Book IXX, Hymn II, Verses 1 and 2) illustrates the place of water in our lives:

> may the waters from the snowy mountains bring health and peace to all people. May the spring waters bring calm to you. May the swift current be pleasing to you; and may the rains be a source of tranquility to all. May the waters of the oasis in the desert be sweet to you; and so be the waters of ponds and lakes. May the waters from wells dug by humans be good to them, and may the healing powers of water be available to all beings.

Hindus consider water to be a powerful medium for purification and also a source of energy. Sometimes, just by the sprinkling of pure water in religious ceremonies, it is believed that purity is achieved. That is why, in the Rig Veda, prayer is offered to the deity of water:

> the waters in the sky, the waters of rivers, and water in the well whose source is the ocean, may all these sacred waters protect me.
>
> (Rig Veda, Book VII, Hymn 49, Verse 2)

Agni (Light/Fire)

Agni is considered in the Vedas as the spring of our life because it creates life on earth. Agni, in later Vedic description, is known as the sun and light. In the form of the sun, Agni is regarded as the soul, and also as the ruler and preserver of the world (Maitrayana Upanishad, Chapter 6, Verse 35).

These five Great Elements, taken together, denote the deep bond between human beings and creation; as such, Hindus are urged to show proper respect and due care for these essential elements.

RESPECT FOR FAUNA IN HINDUISM

The most important aspect of the Hindu religion pertaining to the treatment of animal life is the belief that the Supreme Being was himself incarnated in the form of various species. This Lord says, in one Purana:

> this form is the source and indestructible seed of multifarious incarnations within the universe, and from the particle and portion of this form, different living entities, like demi-gods, animals, human beings and others, are created.
>
> (Srimad-Bhagavata Mahapurana, Book I, Discourse III:5)

This is further demonstrated by a famous series of divine incarnations, as pertinently enunciated by Dr Karan Singh (1986) in the Assisi Declaration. (These were declarations on religion and nature made by religious leaders representing Buddhism, Christianity, Hinduism, Judaism and Islam at the Basilica di S Francesco, Assisi, Italy, 29 September 1986 at the time of the 25th Anniversary of the World Wide Fund for Nature):

> the evolution of life on this planet is symbolized by a series of divine incarnations beginning with fish, moving through amphibious forms and mammals, and then on into human incarnations. This view clearly holds that man did not spring fully formed to dominate the lesser lifeforms, but rather evolved out of these forms itself, and is therefore integrally linked to the whole of creation.

Among the series of incarnations of Vishnu (Vishnu is one of the Hindu Trinity who incarnates on earth to protect righteousness and good), was his first appearance in the form of Matsya (a giant fish), when due to the continuous rain, the entire earth was going to be submerged in water. This giant fish appeared with a mysterious boat into which a human pair went along with samples of all herbs, seeds, and all kinds of living creatures. After the rains stopped, a new creation began. The second incarnation was in the form of Kurma (a tortoise), when because of the churning of the Ksheer Sagar (Milky Ocean), a tortoise was needed to hold Mount Mandarachal, which was being used as a churning pestle. Without churning the sea, the demi-gods would not obtain the nectar to make them invincible when fighting with demons. The third incarnation was in the form of Varaha (a boar): when a demon king Hiranyaksha captured the earth, the boar hid it under massive garbage with unendurable stench and filth; and thus the earth was rescued. The fourth incarnation was in the form of Narasingha (half-man half-lion) to fight the demon king Hiranyakashyap, who after defeating all demi-gods had declared himself to be the God of universe. Since the demon King was indestructible by man or animal, the god Vishnu had to be incarnated in the form of a man–lion. The fifth incarnation was in the form of Vamana (a dwarf) when another demon-king Bali became so powerful that he defeated all demi-gods and conquered the entire universe. So Vishnu appeared in the form of a dwarf brahman, visited the court of Bali, and retrieved the entire universe, and restored demi-gods to their place in heaven. The sixth, seventh, eighth

and ninth incarnations were in the form of humans to protect the earth from oppressors and tyrants. But as Rama (the seventh incarnation), he was closely associated with monkeys, and as Krishna (the eighth incarnation as a cowherd) he was surrounded by cows, peacocks, deer, etc. The ninth incarnation was in the form of the Buddha who preached non-violence towards all creatures. So, since Lord Vishnu was incarnated into various living forms, Hindus accord reverence to species.

The Srimad Bhagavatam Mahapurana further states:

> one should look upon deer, camels, monkeys, donkeys, rats, reptiles, birds, and flies as though they were their own children.
> (Book 7, Discourse XIV:9)

In addition to this, many animals and birds are revered by Hindus as these are consort of various gods, goddesses, and incarnations, as illustrated in Table 1.

Almost all the Hindu scriptures place a strong emphasis on the notion that God's grace cannot be received by killing animals or harming other creatures. That is why not eating meat is considered both appropriate conduct and one's Dharma (Dharma is considered as the Cosmic order, duties and obligations based on social and religious laws handed down by tradition and practices).

Further, in the Manusmriti, a warning is given that:

> a person who kills an animal for meat will die of a violent death as many times as there are hairs of that killed animal.
> (Manusmriti, Chapter 5, Verse 38)

Table 1 Animals and Wildlife Associated with Gods/Goddesses[a]

Animals/Birds	Associated with Gods and Goddesses
Lion	Durga
Wild goose	Brahma
Elephant	Indra, Ganesha
Bull	Shiva
Rat	Ganesha
Swan	Saraswati
Eagle	Vishnu
Serpent	Shiva, Sun
Fish	Kama
Monkey	Rama
Horse	Sun
Peacock	Kartikeya, Saraswati
Parrot	Kama
Owl	Lakshmi
Vulture	Shani
Crocodile	Ganga River
Tortoise	Yamuna River
Tiger	Katyayani
Dog	Bhairava, Dattatreya
Deer	Vayu
Donkey	Shitla
Makar	Kama, Varuna

[a] *Source:* Dwivedi and Tiwari (1987).

Similarly, the Yajnavalkya Smriti warns of hell-fire (Ghora Naraka) to those who are killers of domesticated and protected animals:

> the wicked person who kills animals which are protected has to live in hell-fire for the days equal to the number of hairs on the body of that animal.
> (Yajnavalkya Smriti, Acaradhyayah, Verse 180)

Further, in the Narsingha Purana, it is mentioned that a person who roasts a bird for eating will surely be a sinner.

In Mahabharata, there is a story concerning Rishis and God debating the merits of offering grain or the sacrificial lamb (goat) at the end of Yajna; the Rishis insisted that according to the Vedas, the sacrificial material ought to be grain only. It seems that the practice of grain sacrifice might have started from that time. In summary, Hindu scriptures enjoin its followers from hurting animals.

RESPECT FOR FLORA IN THE HINDU RELIGION

As early as in the time of the Rig Veda, tree worship was quite popular and universal in India. The tree symbolized the various attributes of God to the Vedic seers. The Rig Veda regarded plants as having divine powers, with one entire hymn devoted to their praise, chiefly with reference to their healing properties (Rig Veda, 10.97). During the period of the great epics and Puranas, the Hindu respect for flora expanded further. Trees were considered as being animate, feeling happiness and sorrow. Green trees were likened to a living person, as illustrated by the following verse from the Brihadaranyaka Upanishad (3.9.28):

> just like a tree, the prince of the forest, so the man is, in truth; His hairs are the leaves, his skin resembles the external bark. Out of his skin streams forth the blood, like the juice or the sap out of the tree.
>
> > It flows out from the wounded man, like the sap of the tree, when it is cut.
> > The flesh is comparable to the wood (of the tree), the sinews are like the inner bark;
> > The strong bones are like the inner core of the wood, the marrow resembles the marrow (pith) of the tree.

The Hindu worship of trees and plants has been based partly on utility, but mostly because of the divinity assigned to them. Ancient Hindus considered it their duty to save trees, and in order to do so they attached to every tree a religious sanctity. The following deities, for example, are considered to have made their abode in these trees/plants: Lakshmi in Tulasi (*Ocinlum sanctum*), Shitala in Neem, Vishnu in Pipal/Bodhi (*Ficus religiosa*), Buddha in Ashoka, Shiva in Bilva/Bela (*Aegle marmelos*), Brahma and Vishnu in Vata (*Ficus indica*), Van Durga (tree deity) in Asvathha (*Tropbis aspera*). Table 2 further illustrates the names of

Table 2 Trees and Plants Associated with Gods/Goddesses and Spirits[a]

Trees/plants	Associated with Gods/Goddesses
Asvathha	Vishnu, Lakshmi, Ancestors
Vata	Brahma, Vishnu, Hari, Kuber
Tulasi	Lakshmi, Vishnu, Ancestors
Soma	Moon
Bela	Maheshwar (Shiva)
Ashoka	Buddha, Indra
Amalaki	Lakshmi, Kartikeya
Tala	Buddha, Spirits
Mango	Lakshmi, Govardhan
Kadamba	Krishna
Neem	Shitala, Mansa
Palasa	Brahma, Gandharva
Pipal	Vishnu, Krishna, Ancestors
Fig	Vishnu, Rudra
Narikel (coconut)	Moon
Sheora	Van-Durga, Lakshmi
Sij	Shitala
Tamal	Krishna

[a] *Source:* Dwivedi and Tiwari (1987).

certain trees and plants that are closely associated with various deities.

In India, Nepal and Bhutan, there are many sacred forests and groves where green trees and plants are protected. Also, for Hindus, the planting of a tree is still a religious duty. Thus, sanctity has been attached to many trees and plants. Through such exhortations and various writings, the Hindu religion has provided a system of moral guidelines towards environmental preservation and conservation.

Perhaps this rationale impelled the Hindu law-giver Rishi Manu when he declared that people should not fell green trees even for fuel (Manusmriti, Chapter 11, Verse 64). The cutting of trees and destruction of flora was considered a sinful act. Later, Kautilya's Arthasastra prescribed various punishments for destroying trees and plants (Kautilya's Arthasastra III 19:197):

> for cutting off the tender sprouts of fruit trees, or shady trees in the parks near a city, a fine of six panas shall be imposed; for cutting of the minor branches of the same trees, twelve panas, and for cutting off the big branches, twenty four panas shall be levied. Cutting off the trunks of the same, shall be punished with the first amercement; and felling shall be punished with the middlemost amercement.

Even in modern times, it is popularly believed by Hindus that many trees have their own deity, Vriksha-devata or Van-devi, who is worshipped with prayers and offerings of water, flowers, sweets, and encircled by sacred threads (Dwivedi and Tiwari, 1987). That is why for Hindus, forests were never seen as places of darkness and unknown dangers (akin to what Europeans thought), instead these were places of worship, meditation and intimate harmony.

POLLUTION AND ITS PREVENTION IN HINDU SCRIPTURES

Hindu scriptures reveal a clear conception of what can be called an eco-care system. On this basis, a discipline of environmental ethics developed that formulated codes of conduct (Dharma) and defined humanity's relationship to nature. An important part of conduct is maintaining proper sanitation. In the past, this was considered to be the duty of everyone and any default was a punishable offence. As Kautilya wrote (Kautilya's Arthasastra, Book II, Chapter 36, Verse 145):

> the punishment of one-eighth of a pana should be awarded to those who throw dirt on the roads. For muddy water one-fourth pana, if both are thrown the punishment should be double. If latrine is thrown or caused near a temple, well, or pond, sacred place, or government building, then the punishment should increase gradually by one pana in each case. For urine the punishment should be only half.

Hindus considered the cremation of dead bodies and the sanitary maintenance of the human habitat to be essential acts. When, in about 200 BCE, Charaka wrote about Vikriti (pollution) and diseases, caused by pollution of air and waters, specifically about air pollution (Charaka Samhita, Book Vimanastanam, Chapter III, Verse 6.1), he said:

> the polluted air is mixed with unhealthy elements. The air is uncharacteristic of the season, full of moisture, stormy, hard to breath, icy cool, hot and dry, harmful, roaring, coming at the same time from all directions, bad smelling, oily, full of dirt, sand, steam, creating diseases in the body and is considered polluted.

And about water pollution, he wrote (Charaka Samhita, Book Vimanastanam, Chapter III, Verse 6.2):

> water is considered polluted when it is excessively smelly, unnatural in colour, taste and touch, slimy, not frequented by aquatic birds, aquatic life is reduced, and the appearance is unpleasing.

The healing properties and medicinal value of water have been universally accepted – provided it is pure and free from all pollution. Ancient Indian thinkers were aware of the reasons for polluted water. That is why Manu advised:

> One should not cause urine, stool, cough in the water. Anything which is mixed with these un-pious objects, blood and poison, should not be thrown into water.
>
> (Manusmriti, Book IV, Verse 56)

Today, many rivers are still considered sacred. Among these, the river Ganga is considered by Hindus as the most sacred body of water. In Pravascitta Tatva (1.535), disposal of human waste or other pollutants there has been prohibited since time immemorial (Dwivedi and Tiwari, 1987, 84):

> one should not perform these 14 acts near the holy waters of the river Ganga: i.e., putting excrement, brushing and gargling,

> removing cerumen from body, throwing hairs, dry garlands, playing in water, taking donations, performing sex, having attachment with other sacred places, praising other holy places, washing clothes, throwing dirty clothes, thumping water and swimming.

Needless to say, this prohibition has been more honored in the breach than the observance nowadays.

On pollution in general, the great epic, Mahabharata mentions that:

> from pollution, two types of diseases occur in human beings. The first, which is related with body and the other with mind, and both are inter-connected. One follows the other and none exists without the other.
>
> (Mahabharata, Rajdharmanusasanparva, Chapter 16, Verses 8 9)

The above-listed examples show that during ancient times, eco-care was proclaimed, and probably practiced where possible. Through these injunctions and religious duties, a mechanism was developed to create a proper respect for nature a mechanism based on cosmic ordinance and divine law which provided a base for eco-spirituality.

KARMA, THE CYCLE OF BIRTH AND REBIRTH AND THE ENVIRONMENT

Karma means all deeds/actions performed and their consequences, which govern a person s life, and which may continue in the next life because of the philosophy of the migration of soul from one birth to another. People often confuse the Law of Karma with the Law of destiny. The Law of Karma may be said to mean that each act, willfully performed, leaves a consequence in its wake. These consequences, also called Karma-Phala (fruits or effects of action) remain always with us, although their impact may not be felt immediately. It also means that every action performed creates its own chain of reactions and events, some of which are immediately visible, while others take time to surface. Environmental pollution is but one example of the Karma of those people who thought that they could continue polluting the environment without realizing the consequences of their actions for future generations. As a matter of fact, there is a boomerang effect of our Karma; or to put it another way, whatever action we do on others recoils, although not always by a direct reaction and not immediately but often by unconnected ways, on our lives, and sometimes in its own exact measure (Dwivedi, 1994).

Once the cycle of Karma starts, it continues without a break; and although a person may be dead, yet Karma survives in the form of a memory on to the next life of a departed soul. As it is mentioned in Mahabharata:

> an action which has been committed by a human being in this life, follows him again and again (whether he wishes it or not).
>
> (Shanti Parva, 139:22)

It is difficult to say when a human being first got involved in the cycle of Karma, but once a person is in it, he/she cannot escape, even if incarnated in new and different forms in this world. The main reason for its continuation is the indestructible nature of the energy of Karma; it is this energy that may appear today under one name and form, but will reappear under another name and form when the former has died. In this way, Karma is related to the Hindu concept of re-birth (Punarjanma) because the reappearance in various forms is the cycle of birth and death. That is why, in Hindu scriptures, the Atman (soul) never dies, it is eternal, but at the same time it is involved in the cycle of Karma. It is for this reason that Hindus believe that one must suffer tomorrow for what one does today; and the day after tomorrow, for what one does tomorrow; and finally, one suffers in the next life for what one does in this life; and in this way the cycle of Punarjanma continues. This is what was also said by Bhisma to King Yudhisthira after the Great War of Mahabharata:

> O King, although a particular person may not be seen suffering the results of his evil actions, yet his children and grandchildren as well as great grandchildren will have to suffer the results of those actions.
>
> (Mahabharata, Shanti Parva, 129:21)

The environmental crisis facing humanity today relates to the concept of Karma, which becomes even more significant. For in Hindu scripture, the rewards or punishment of Karma are described as events that will happen in the future, and sacrifice is described as Apurva (futuristic) Karma-Phala, the results of which have not yet been seen. We need to realize that the destruction that we are inflicting on our natural surroundings will have future repercussions, which will be felt not only by our children, but also by ourselves due to the Law of Karma, which causes us to return to earth in a subsequent birth.

If we recognize and act on this philosophy of life, then and only then will people start paying due respect to nature as well as taking a stake in the care for the environment. Finally, the concept of Karma envisions an interrelatedness between what we do in this world and what may result now and/or in the future. This appreciation is the key to the point being made here. All of our actions are interrelated with and interconnected to what eventually happens in this world. Although we may not face the consequences individually, nevertheless, someone else will be burdened with or benefit from our actions. It is in this context that the concept of Karma as a guiding force to protect the environment becomes meaningful.

The Hindu belief in the cycle of birth and rebirth, wherein a person may come back as an animal or a bird, gives these species not only respect, but also reverence. This provides a solid foundation for the doctrine of Ahimsa non-violence (or non-injury) against animals and human beings alike. Hindus have a deep faith in the doctrine of non-violence. It

should be noted that the doctrine of Ahimsa presupposes the doctrine of Karma and the doctrine of rebirth (punarjanma). The soul is continually reborn in different life forms such as birds, fish, animals, and humans. Based on this belief, there is a profound opposition in the Hindu religion (as well as in Buddhist and Jain religions) to the institutionalized killing of animals, birds and fish for human consumption. Not only, as mentioned, do almost all of the Hindu scriptures place strong emphasis on the notion that God's grace can be received by not killing his creatures or harming his creation (Dwivedi, 1997a); but further, the pain a human being causes to other living creatures will eventually return to that person later, either in this life or in a later rebirth. It is through the transmigration of the soul that a link is provided between the lowliest forms of life with human beings.

HINDU ECO-SPIRITUALITY TODAY?

Hindu eco-spirituality, in ancient and medieval times, has provided a system of moral guidelines towards environmental preservation and conservation. Environmental ethics, as propounded by ancient Hindu scriptures and seers, were practiced not only by common persons, but even by rulers and kings. They observed these fundamentals, sometimes as religious duties, often as rules of administration or obligations for law and order, but always as principles properly knitted into the Hindu way of life. That way of life enabled Hindus, as well as other religious groups residing in India, to carefully use natural resources, but not to have any divine power of control and dominion over nature and its elements.

If such has been the tradition, philosophy, and ideology of Hindu religion, what then are the reasons behind the present state of environmental crisis facing India; and more specifically, the seeming indifference about environmental protection and conservation among the masses? As we have seen, ethical beliefs and religious values influence people's behavior towards others, including our relationship with all creatures and plant life. If, for some reason, those noble values become displaced by other beliefs, that are either thrust upon the society or transplanted from another culture through invasion (as happened later in India), then the faith of the masses in its earlier spiritual tradition is shaken.

Given about nine centuries of foreign religious and cultural domination by Islamic and Christian cultures, which penetrated all levels of Hindu society, appropriate answers and leadership did not come from its religious leaders and priests; consequently, the masses became ritualistic and inward looking. Added to this are the forces of materialism, consumerism, individual and corporate greed, and the capriciousness and corruption among politicians, bureaucrats and business people. Under such circumstances, religious values that acted as sanctions against environmental destruction have been sidelined as those insidious forces inhibit the religion from continuing to transmit the ancient values which encouraged respect and due regard for God's Creation (Dwivedi, 2000b).

How can the original ancient values and wisdom be transmitted into practice? Can there be an approach for a Dharmic ecology? Can there be a practical Dharmic ecology? And can it be practiced in India?

Many people wrongly believe that India is a Hindu country, not realizing that it is a secular state where secularism, as practiced nowadays, means a disregard for all religions, especially the mainstream Hindu religion and culture. As such, it will take time for any Dharmic ecology to be operationalized in India. Besides, it is not sufficient to examine and extol the ancient wisdom of Hindu seers, to dwell on the Vedic and Puranic heritage, and then simply hope that a self-correcting process and automatic implementation of those noble ideas will take place to remedy those environmental problems.

What is more important is how to put into practice an ecological vision and to make it relevant to modern times. A common strategy for environmental stewardship needs to be developed so that, in the end, people will subscribe to an environmentally caring world. That strategy requires that people show their commitment and care, both individually and collectively, for Mother Earth, and for her natural gifts, which sustain our life-system. Because unless people are able to inculcate eco-care vision, there will be no sustainable future.

It is worth pointing out in this context that we can draw on the powerful concept of *satyagraha*, which literally means persistence and endurance for the truth. This concept excludes the use of violence, because it is believed that, since humans are not capable of knowing absolute truth, we are not competent to punish. The word *satyagraha* was initially coined in South Africa by the most famous modern Indian, Mahatma Gandhi (*see* **Gandhi, Mohandas Karamchand**, Volume 5) to distinguish the non-violent resistance of the Indians of South Africa from the contemporary passive resistance of suffragettes and others. Non-violent resistance embodies five basic elements that ought to be followed by those who wish to use this technique. These five elements are purity of: (a) motive; (b) means to be used; (c) suitability of place; (d) time; and (e) the mental status of the doer/agent. An action is a vishuddha dharmic ashtra (a righteous and proper weapon) if it meets those five conditions. Thus, satyagraha is not conceived as a weapon for the weak only; furthermore, it is different from civil disobedience, passive resistance, and non-cooperation.

Satyagraha differs from passive resistance in that the latter has been regarded as a weapon of the feeble. While it avoids violence, passive resistance does not

exclude the use of violence if, in the opinion of the passive resister, the occasion demands it. However, it has always been distinguished from armed resistance, and its use was at one time confined to the Christian martyrs.

Civil disobedience, although being a branch of Satyagraha, is still different to non-violent resistance. Civil disobedience is a response to immoral statutory enactments, and signifies a person's displeasure with some statutory law (it was first used to show displeasure at paying taxes). Civil disobedience presupposes the habit of willing obedience to laws without fear of sanctions; therefore, it can be practiced only as a last resort and by a select few in the first instance at any rate (Gandhi, 1961, 325). Furthermore, it should be noted that non-cooperation predominantly consists of the individual withdrawing cooperation from the state that has become corrupt or immoral, but excludes the use of civil disobedience which results in state-inflicted punishment. Civil disobedience is a branch of Satyagraha, for it can be practiced by children and the masses, but it does differ in fundamentals.

Carried to its utmost limit, Satyagraha is independent of monetary or other material assistance, and definitely independent of physical force or violence. As Gandhi said:

> Indeed, violence is the negation of this great spiritual force, which can only be cultivated or wielded by those who will entirely eschew violence.
>
> (Gandhi, 1961, p. 34)

It is a force that may be used by individuals and communities, and which may be used in domestic as well as political affairs. This universal applicability is thus an example of its permanence and invincibility. It can be used by men, women and children, as long as they are not capable of meeting violence by violence. Therefore, Gandhi believed satyagraha to be an effective tool in the fight for truth and a basis for non-violent resistance.

In relation to the environmental crisis, this Gandhian philosophy has been effectively used in India. The example of the Chipko movement is an illustration that non-violent resistance can work toward environmental protection (Dwivedi, 1997b) (*see* Chipko Movement, Volume 5). Another example is the Narmada Bachao Andolan (the movement to save Narmada River from damming), which has forced the World Bank to reconsider its loan to India for that massive hydroelectricity project.

We therefore need to consider a satyagraha for the environment saturated with the concepts of eco-care and Dharmic ecology; and we need to become effective advocates and practitioners of this approach, rather than staying on the sidelines. Hindu religious leaders should:

- take initiative and help secular institutions by providing timely and appropriate advice to encourage greater integration of eco-care approaches into the educational curricula;
- strengthen the capability of secular institutions to meet their goals of sustainable development and environmental conservation;
- promote the important concept of Sarva bhoot hitey ratah (serving all beings equally);
- take the lead in promoting the concept of Vasudhaiv Kutumbakam, i.e., the family of Mother Earth, and the obligation of humanity to accept a world of material limits;
- protect and restore places of ecological, cultural, aesthetic and spiritual significance; and
- build partnerships across social, economic, political and environmental sectors, including dialogue with other religions and spiritual traditions (Dwivedi, 2000a).

The choice before the Hindu religion (as well as before all other religions) is either to care for the environment or be a silent participant in the destruction of planetary resources. Partnership with secular institutions must be forged and cooperation fostered at local, regional, national and international levels. An environmental and sustainable development strategy, based on the lines suggested above, could offer a way of bridging the gap and making the essential link between secular, scientific and spiritual forces.

NOTES

Verses quoted in English from various Upanishads are from Deussen (1980); verses in Sanskrit for Isavasya Upanishad, Aitareya Upanishad and Shvetashvatara Upanishad are from Upanishad Anka of Kalyan (1949).

Homocentric

Carolyn Merchant (1992, *Radical Ecology*) applies the term *homocentric* to an anthropocentric position that fosters care and stewardship for nature – for humanistic as distinct from ecocentric reasons. Since the environment is crucial to human well-being and survival, then we have an indirect duty towards it – one derived from communal human interests. This means assuring that the Earth remains environmentally hospitable to human life, and that its beauty and resources are preserved so human life may continue to be pleasant. As such, *homocentrism* is to be further distinguished from *egocentrism*, where the latter is an anthropocentrism based on prioritizing the desires of individuals rather than the communal good. Egocentrism underpins laissez-faire capitalism, with its inherent tendencies to exploit the environment, whereas homocentrism would, at the very least, regulate the market for the sake of wider social and environmental goals – or even replace capitalism by socialism. Both utilitarianism and Marxism espouse a homocentric ethic, hence eco-socialism is a homocentric variety of radical environmentalism, as is, according to Merchant, social ecology.

Homocentric ethics focus on society, therefore emphasizing the social good and social justice flowing from the (Christian) ethic of environmental stewardship. Unlike ecocentrism, which would protect nature for its intrinsic value, homocentrism's utilitarianism would allow managed transformation of nature where the resulting sum of human welfare was to be increased over that accruing by leaving it alone.

As Merchant describes it, homocentrism's ethics combine the mechanistic approach of egocentrism with the organicism of *ecocentrism*. Effectively this means that

homocentrism would apply science and technology derived from analytical and reductionist thinking in the cause of furthering what is seen as an intimate, organic and dialectical relationship between society and nature (*see* Ecocentric, Biocentric, Gaiacentric, Volume 5).

Human Body, Immediate Environment

Catriona Sandilands
York University, Toronto, Canada

The human body is a site of environmental change at a variety of levels. Perhaps most obviously, the impacts of many environmental problems are tangibly experienced by human beings as bodily symptoms; from sunburns to cancers, environmental degradation becomes part of everyday knowledge for many people through questions of bodily harm and danger. In this view, the body is a site for research concerning the consequences of particular environmental changes on human life; it is also a powerful trope for forms of political mobilization that link human health and environmental protection, including breast cancer and anti-nuclear activism.

Broadly speaking, the human body is the site of our primary physical experience and knowledge of environments; we interact with our environments through (at least) the bodily processes of touch, taste, smell, sight and hearing. These sensory sources of knowledge are influenced by our species physiology (e.g., human beings have differently organized senses than bees), but also by our specific cultures and activities (e.g., automobile travel, horseback riding and walking lead to very different views of a landscape). Viewed as sites where culture and physiology interact, bodies are important for understanding both ontological and epistemological dimensions of environmental change.

According to geographer Neil Smith, the body is a socially and physiologically constituted scale of place in which varied changes occur and interact, including biological maturation and decay, social identification and differentiation, and daily and intergenerational reproduction (Smith, 1991). In this sense, the human body is an environment, a site in and over which multiple conflicts and struggles take place: access, control, pleasure and pain, health, meaning, interpretation, mobility. The physical/social constitution of the body can thus be seen as a site of environmental change. Larger-scale environmental processes can also be understood as having specific manifestations in the environment of the body; the human body is understood not just as an effect of other scales of change but as a unique site where changes occur in particular ways, at least in part because of particular social and cultural relations of that scale. The prevalence and distribution of breast cancers in industrialized nations, for example, cannot be understood without reference both to the physiological impact of environmental hazards on women's bodies (e.g., the presence of organochlorines in water and consumer products) and to the complex social relations in and through which women's bodies have different histories (e.g., of such risk factors as exposure to toxins, access to health care and experiences of childbearing, variously affected by class, race, ability and sexual orientation). Altogether, these factors highlight the complexity of body/environment politics and the importance of an approach to environmental change that includes social and cultural elements; we are not, in fact, all in the same boat.

In a related vein, Elizabeth Grosz argues that bodies and environments are mutually defining (Grosz, 1995). Environments – including both their biological and cultural elements – orient and organize bodily senses and perceptual (spatial) information; they also leave traces on and in the body in the form of symptoms but also memories and desires. These impacts inspire particular forms of bodily action, in which the body becomes a site or agent of intervention into that environment. For example, a hot and humid day may inspire some people to use air conditioning and others to enjoy the heat; the more people that choose the former, the more energy use and air pollution, thus having an impact on the atmosphere, etc. Far from there being a single, natural reaction to an environmental change, bodies are encultured (e.g., one's preference for cooler or warmer temperatures is, at least in part, a question of memory and desire); they are also active participants in the environments that shape them.

Although this understanding of mutual influence between bodies and environments may seem commonsensical, it is important to note its implications. First, as Grosz (1995, 109) writes, if bodies are not ••• pregiven, ••• environments cannot alienate the very bodies they produce . In other words, there is no single ideal environment for the body, and the appropriateness of any given one has a great deal to do with social and cultural factors (this is not to say that there are no limits to possibility, only that there is certainly more than one). Second, if bodies and environments are involved in a dialectical relationship, and if there

is no single and biologically *a priori* template for the ideal form of this relationship, then it becomes of paramount importance for environmentalists to investigate a variety of different axes of in uence. Speci cally, as is suggested in much contemporary environmental thought, forms of social, political, and economic power have an enormous effect not only on bodies and environments individually, but on their modes of interaction.

In these respects, the ontological question of mutual body/environment in uence is also an epistemological question; bodies shape knowledge of environments, and *vice versa*. Although sensory experience is clearly part of the creation of this knowledge, it is also the case that more socially and culturally sedimented in uences are at work. Bodies and environments can, in the terms of social theory, thus be understood as sites of *inscription* (meaning that they are partly de ned by culture) and as elements of *discourse* (meaning that they circulate as signs within the realm of language, artifact and culture). Such understandings are signi cant because they point to the fact that representations of the human body as environment are, in fact, themselves an important part of the process of environmental change. For example, the metaphorical understanding of the earth as a human body, often (as in the case of some Gaia imagery) a female one, has led historically (and may continue to lead) to particular, often damaging assumptions about the nature of each.

Indigenous Knowledge, Peoples and Sustainable Practice

Douglas Nakashima[1] and Marie Roué[2]

[1] *UNESCO, Paris, France*

[2] *Centre National de la Recherche Scientifique, Paris, France*

Indigenous knowledge is entering into the mainstream of sustainable development and biodiversity conservation discourse. Article 8(j) of the Convention of Biological Diversity (Rio, 1992) has contributed to this process by requiring signatories to: " respect, preserve and maintain knowledge, innovations and practices of indigenous and local communities embodying traditional life-styles relevant for the conservation and sustainable use of biological diversity" . As the potential contribution of indigenous knowledge to key items on the global agenda gains widening recognition, an increasing number of scientists and policy-makers are calling for the integration of indigenous and science-based knowledge.

While indigenous peoples who have been lobbying for such recognition have reason to be satis ed, there are also reasons for concern. Are scientists serious enough about this emerging issue to go so far as to question the construction of their own knowledge? Or at the end of the day, will they do little more than add a veneer of traditional ecological knowledge (TEK) and then carry on business as usual? For the time being, the scienti c and the development communities views indigenous knowledge rst and foremost as a resource to be appropriated and exploited. Integration with (or more accurately into) science implies the application of a validation process based on scienti c criteria that purportedly separates the useful from the useless, objective from subjective, indigenous 'science' from indigenous 'beliefs'. Through this process, knowledge corresponding with the paradigm of Western science is extracted, and the rest is rejected. While this cognitive mining may be pro table to science, it threatens indigenous knowledge systems with dismemberment and dispossession.

INDIGENOUS, LOCAL OR TRADITIONAL ECOLOGICAL KNOWLEDGE (TEK)?

The challenge of understanding *indigenous knowledge* begins with the perplexing task of deciding how it should be named. On this matter, few persons agree. Or to be more precise, everyone recognizes that existing terms are for one reason or another unsatisfactory. Should one speak of TEK, the term coined when the field emerged in the public arena in the 1980s? Or abandon this designation in favor of the term indigenous knowledge? TEK has the advantage of immediately evoking the temporal depth of these sets of knowledge and of clearly flagging their domain, that of nature, while at the same time raising the question of their relationship to the ecological sciences. Associating the term traditional, however, with societies that, in the not so distant past, were dismissed as primitive or savage raises the phantom of social Darwinism. The term is all the more inappropriate, if our penchant for constructing binary oppositions leads us to conceive traditional

as a counterpoint to modern, and to think of traditional knowledge as fixed in the past and not susceptible to change. Finally, it may be misleading to apply the term ecological to sets of knowledge whose content and nature extend well beyond the confines of one scientific discipline to include such knowledge as the movements of constellations, the strength of ocean currents or the elasticity of sea ice, and to encompass not only empirical knowledge, but also practices and know-how, value systems, ways of life and worldviews. The fact is that indigenous peoples do not share the dichotomous occidental worldview that separates the material from the spiritual, nature from culture, and humankind from all other life forms, and as a result they do not do science in isolation from other pursuits.

While the label *indigenous knowledge* has the advantage of explicitly designating one of the groups of peoples most concerned – those who designate themselves as indigenous peoples, it raises other concerns. Who is indigenous and who is not? What peoples wish to be designated by this term and which do not? Indeed, this label is poorly adapted to the realities of Asia and Africa, where all peoples are native and any attempt to designate one group as indigenous but not another, provokes confusion. In these regions, unlike in the Americas or Australia, histories of human occupation have not followed a pattern whereby a wave of colonizers coming from abroad has supplanted or dominated a population that, due to its earlier and lengthy presence, is clearly identifiable as aboriginal or indigenous. Furthermore, in several African countries, particularly former colonies of francophone nations, the label indigenous has retained a strongly negative connotation due to its past history of use by colonial oppressors. For this reason, the expression *farmers knowledge* and *local knowledge* are sometimes preferred. The term local knowledge has the additional advantage of not excluding non-indigenous farmers, fishers, health practitioners and others whose extensive knowledge of the natural milieu is also a product of resource-based livelihoods extending across many generations. Its major weakness is a lack of specificity, as most knowledge can be labeled local.

Faced with the complexities of defining indigenous, special rapporteur J R Martinez Cobo provided a report in 1983 to the United Nations (UN) Sub-Commission on Prevention of Discrimination and Protection of Minorities, in which he stressed the right of indigenous peoples themselves to define what and who is indigenous. Further to this principle of self-identification, criteria retained to define the quality of being indigenous include common ancestry with original occupants, a distinct ethnic identity and shared patterns of vulnerability. These definitions are clearly of a political nature. They offer peoples encapsulated within states that may be reluctant to recognize territorial rights or the right to pursue a distinctive way of life, an opportunity to assert their difference and their collective identity. The debate on who and what to define as indigenous is far from closed, and it is unlikely that any single definition will satisfy all parties. Today, the UN Working Group of Indigenous Peoples estimates the world population of indigenous peoples as some 300 million, belonging to some 5000 groups in more than 70 countries, the largest population residing in Asia.

WHAT IS INDIGENOUS KNOWLEDGE?

Indigenous knowledge systems are the complex arrays of knowledge, know-how, practices and representations that guide human societies in their innumerable interactions with the natural milieu: agriculture and animal husbandry; hunting, fishing and gathering; struggles against disease and injury; naming and explaining natural phenomena; and strategies for coping with changing environments. It is through this fine-grained interplay between society and environment that indigenous knowledge systems have developed diverse structures and content; complexity, versatility and pragmatism; and distinctive patterns of interpretation anchored in specific worldviews. Whereas knowledge is conceived in Western culture as an abstract entity independent from practice (e.g., science as opposed to technology), such a compartmentalized view is alien to indigenous societies. It would be self-defeating to consider farmers' knowledge of rain patterns, soil types and crop varieties apart from the ways in which this information is put into practice in their fields. In other words, indigenous knowledge includes not only knowledge but also know-how. Transmission is not only oral, but also in the context of doing (Figure 1). Finally, unlike science, indigenous knowledge does not oppose the secular to the spiritual, and therefore does not separate the empirical and objective from the sacred and intuitive. In indigenous societies, such boundaries are permeable. On the one hand, much knowledge of nature falls within the empirical realm. Hunters have detailed knowledge of the habitat, behavior, diet and migration patterns of their prey. Farmers know how crops should be rotated to maintain soil fertility and which plant products have insecticidal or medicinal properties. This science of the concrete', however, blends imperceptibly into the metaphysical realm. For the hunter, the success of the hunt is as much due to assistance from spirit helpers, as it is to skillful tracking and steady shooting. The continued flow of water for the farmers' field is attributed as much to their respect for the deity of the sacred headwater forests, as to the water-drawing properties of the trees themselves. The concrete and the spiritual co-exist side by side, complementing and enriching rather then competing and contradicting.

Figure 1 Knowledge transmission through observation and practice: young Inuk boy helping his father skin and butcher a caribou (*Rangifer tarrandus*) on the banks of the Kuujjuaq River (Arctic Quebec, Canada). (Photo by D Nakashima)

ON THE NATURE OF THE ''SCIENCE OF THE CONCRETE''

While the current wave of interest in indigenous knowledge dates back no more than a few decades, the knowledge systems themselves have accompanied humankind through countless millennia of environmental change and cultural adaptation. The societies that developed them did not wait for official recognition before forging cultural landscapes and domesticating plants and animals that continue to play a major role in today's global economy. In 1962, Claude Levi-Strauss, a philosopher and renowned anthropologist, published his seminal work on *The Savage Mind*. In his opening chapter entitled the *The Science of the Concrete*, he reflects on the nature and character of indigenous knowledge, which he also qualifies as mythical thought (Levi-Strauss, 1962). More recently, Berkes (1999), a human ecologist, has dedicated a book to indigenous knowledge entitled *Sacred Ecology*. Between the early work of Levi-Strauss and Berkes' recent overview, numerous observers have pondered over these knowledge systems. While some accord them great value and others dismiss them as nonsense, their dual nature, combining the material and the spiritual, has been evident to all.

The first scientist to dedicate himself to the contemporary study of indigenous knowledge was Harold Conklin, who completed his thesis at Yale University in 1954 on *The Relations of Hanunoo Culture to the Plant World* (Conklin, 1954) (the Hanunoo are indigenous peoples of the Philippines). Pioneering a new discipline, ethnoscience, which would later come to be called the new ethnography, he dedicated himself to the study of a society's knowledge of its natural environment, through the examination of indigenous semantic categories. It is true that studies of human relations with plants and animals existed well before the 1950s, and that this intellectual tradition continues to this day under various labels composed of the prefix ethno-, followed by a qualifying term: ethnobotany, ethnozoology, ethnominerology. Ethnoscience, however, introduced a radically different approach that focused upon the knowledge of nature possessed by local peoples themselves. Unlike ethnobotany or colonial economic botany, which are basically applied Occidental sciences carried out in exotic locations and among exotic' peoples, ethnoscience strives to understand the view from within (an indigenous worldview). As a branch of cognitive anthropology, it focuses upon elucidating a cultural grammar, structures of thought built into the local language. For the first time, the recording of indigenous taxonomies was to reveal not only the breadth of a people's knowledge, but also insights into its very nature (cf. Friedeburg, 1979; Bulmer, 1979; Berlin, 1992; Ellen, 1993).

The classificatory prowess of indigenous peoples is on a par with that of scientists. As Levi-Strauss has amply demonstrated, the breadth of indigenous taxonomic knowledge is impressive: a single Seminole informant can identify 250 plant varieties and species, Hopi Indians recognize 350 plants, the Navajo more than 500. The Subanun of the Philippines use more than 1000 botanical terms and the Hanunoo, close to 2000. The diversity and sophistication of plant and animal use also attests to the subtlety of indigenous observations and the capacity to systematize knowledge and know-how. The Buriyat of Siberia, for example, derive from a single species, the bear, no less than 52 therapeutic applications: seven distinct uses for the

meat, five for the blood, nine for the fat, 12 for the brain, 17 for the bile, and two for the fur, etc.

As impressive as these figures may be, for the Hanunoo, plants are not the stuff of lists, but rather objects of passionate and prolonged debate. Having rigorously recorded Hanunoo discussions during and after the evening meal, Conklin concluded that plants, especially cultivated varieties, were the focus of a majority of exchanges. Combining the expertise and interests of systematic and economic botanists, Hanunoo conversations centered upon the hundreds of characteristics which differentiate plant types and often indicate significant features of medicinal or nutritional value (Conklin, 1954, 97). This knowledge is acquired very young and expanded throughout an entire lifetime. One morning, a seven-year-old Hanunoo girl surprised Conklin by suggesting that he show her the pictures of Brown's three-volume guide to useful plants of the Philippines. On her own initiative, she began to comment on the text, assigning each plant a hanunoo name, or solemnly declaring that she had not seen that plant before.' At the end of her remarkable performance, she had identified 51 out of 75 plants with only two errors!

While a science of the concrete' might be expected to have practical applications as its sole preoccupation, Levi-Strauss argues that indigenous knowledge is motivated by considerations other than utility. He cites Speck, for example, who has documented for the Indians of northeastern US and eastern Canada, an extensive herpetological taxonomy that is comprised of distinct terms not only for each genus, but also for species and certain varieties. Yet this knowledge is not practical, as reptiles and amphibians have no economic utility for these groups. Similarly, not only do the Pygmies distinguish between a phenomenal number of plants and animals, but they have also developed detailed knowledge of the habits and behavior of several species, including bats, that cannot be considered to be useful to them. These and other examples, drawn from numerous observers in diverse societies, have led Levi-Strauss to conclude that it is not, as one might expect, use that leads to knowledge. Of the endless trials conducted for the sake of knowing, only a few end up providing useful results:

> ••• animals and plants are not known because they are useful, they are found to be useful or interesting because they are first known .
>
> (Levi-Strauss, 1966, 9)

THE EPISTEMOLOGY OF SCIENCE AND OF INDIGENOUS KNOWLEDGE

The image of the Other held by the West shifts from one extreme to another. Since the time of the first encounter, indigenous peoples have always been a source of fascination. For many Occidentals they embody the ultimate otherness and, as such, they have been the object of both admiration and scorn. Are the savages' the embodiment of our unattainable dreams of freedom, courage, purity, simplicity and social equality? Or are they, as we imagine we were before becoming civilized' – cunning, cruel, ignorant, without faith or order, heeding only the law of the jungle? Until the development of cultural ecology in the 1960s (Lee and Devore, 1968), hunters and gatherers were portrayed as our poor backward cousins, struggling through great efforts and pains to maintain themselves just at the brink of survival. Subsequently, they became the distinguished representatives of what Sahlins (1972) has termed the original affluent society, rich not in material wealth, but luxuriating in time freed by the efficacy of their adaptation to the natural milieu and the adoption of a non-consumptive (Zen) lifestyle. Given these enduring disparities between our views of indigenous peoples, the deep ambivalence of our contemporary discourse on indigenous knowledge should come as no surprise. It is through pronouncements about the Other that Western society plays out its own doubts and fears. In this period of global change, have advances in science and technology brought well-being or alienation to our societies?

Whenever the issue of indigenous knowledge is discussed, sooner or later the recurrent question of validity is raised. Is it scientific? Or, being composed of odds and ends, does it combine the best with the worst, juxtaposing without distinction empirical observations and obscure superstitions?

As a first response, we must understand the persons behind the question. Science is a social construction of our own society, which being modern and Occidental is determined both historically and geographically. It presupposes a separation of the spiritual from the material, of religion from knowledge, and of culture from nature. Such a dissected worldview is not shared by indigenous cultures whose philosophy is better characterized as a cosmovision or as holistic. For this reason, qualifying the knowledge of indigenous people as science is both misrepresentation and reductionism. Nevertheless, this fallacious and futile approach of seeking ourselves in the Other has provided the basis for an entire critique of indigenous knowledge. It is formulated in most cases as negative definitions, i.e., what indigenous knowledge is not. For example, science defines itself as experimental (deductions from hypotheses are tested), systematic (results can be replicated) and universal (results are independent from context, as variables are isolated and controlled). In contrast, indigenous knowledge is often said to be practical (determined by immediate need and utility), local (only applicable in the setting in which it was developed) and contingent (context dependent).

Some even speculate whether this knowledge might lie somewhere between perception and conception, and better be considered as much skill, as concept (Sillitoe, 1998, 229). How do New Guinea highlanders assess the quality of their soil? Even if the results of their analysis do not differ from that of the agronomist, they are reprimanded for not being able to offer up on a platter the analytical discourse that the scientist requires. When asked to explain why or how, they reply: If one is a farmer, one just knows . But in this dialogue between the deaf, where are the barriers and to whose limits are they due? Scientists conclude that indigenous people lack the analytical capacity to raise their skills from the plane of the local and pragmatic to that of the systematized and universal (Sillitoe, 1998). But as Sillitoe's comments suggest, highlander farmers are undoubtedly equally frustrated by the difficulty of communicating their knowledge to scientists, and bewildered by the constraints that the latter impose on how knowledge must be packaged. Instead of opening all intellectual and sensorial pathways (touch, smell, taste, sight, sound) and accepting the farmer's invitation to feel the texture of the soil, smell its composition or taste its acidity, scientists narrow-mindedly insist that explanations pass by the single limited channel of an intellectual discourse compatible with the Occidental literate tradition. For the scientist, if a farmer's knowledge cannot be reduced to the written word, then it is not knowledge, but remains merely skills.

All of these criticisms (or more politely, definitions of what indigenous knowledge is not) arise from our own ethnocentrism and an inability to extricate ourselves from our own culturally-embedded point of view.

KNOWLEDGE AS A BASIS FOR SUSTAINABLE PRACTICE

Overshadowed by the pomp and promise of modern science and technology, indigenous knowledge systems have been disregarded until recently. While scientists and development agencies are only beginning to acknowledge their significance, their enduring role as the mainstay of local food production and health care in the developing world cannot be questioned. In sub-Saharan Africa, for example, local knowledge guides the decisions and practices of small-scale farmers who represent 70–90% of agricultural producers and more than 60% of the population. Artisanal fishers, who represent more than 90% of the fisheries work force world-wide, rely on their own knowledge and skills to locate fish, navigate safely at sea and bring home the catch. Similarly, it is estimated that some 80% of the world's population fulfills their primary health needs through the use of traditional medicines. Even in industrialized countries, local knowledge accumulated across generations continues to play a fundamental role in sustaining localized resource use practices whether they be small-scale farming, fishing, trapping or the gathering of wild produce.

Since the 1992 UN Conference on Environment and Development, and in particular the coming into force of the Convention on Biological Diversity, increasing attention has been drawn to the contributions that indigenous knowledge can make to global biodiversity conservation objectives. This emerging role for indigenous knowledge holders has flowed quite naturally from the recognition that most remaining regions of the world that are biodiversity rich are also homelands for traditional and indigenous peoples. This is no simple coincidence, as in sharp contrast with the biodiversity impoverishment that accompanies the processes of modernization and industrialization, the persistence of traditional ways of life has gone hand in hand with the maintenance of local ecological systems and the conservation, and even enhancement, of biodiversity. In these areas represented as wilderness or virgin in the Western mind, indigenous knowledge participates in the transformation of nature to create cultural landscapes, the products of social system–ecosystem interaction. One dramatic, but by no means unique, example of this process is the use of fire by Aboriginal peoples in Australia to create landscapes that are ecological mosaics (cf. Case Study 1 below). This sustainable practice, which is vital for maintaining biological diversity, has now been integrated into National Park policy in certain parts of Australia through directives that explicitly call for the reinstatement of traditional Aboriginal burning regimes.

Inventories of local biodiversity can also benefit from knowledge encoded in local languages in the form of indigenous categories of natural objects. Finally, as indigenous peoples retain within their knowledge systems an inter-generational memory of fluctuations, trends and exceptional events in relation to the local environment, they can contribute importantly to understanding processes of change, whether these might be long-term, global transformation processes or circumscribed local events. The invaluable contribution of indigenous knowledge to environmental and social impact assessment processes, for example, has been convincingly demonstrated.

Modernization and uniformization of agricultural practices has also triggered a severe loss of biological diversity of domestic plant and animal stocks. Here again, pastoral and peasant communities that have maintained traditional modes of production have today become the major custodians of the world's crop and domestic animal diversity. In tropical agroecosystems in Thailand and Indonesia, for example, peasants commonly maintain more than 100 domestic plant species, as well as harboring in their paddies, rice varieties adapted to a range of environmental conditions (Altieri, 1999). Slash and burn agriculture as practiced by the Karen of northern Thailand offers one example of a sustainable farming system based upon indigenous knowledge

and practice, that enhances biological diversity (cf. Case Study 2 herein).

CASE STUDY 1: ABORIGINAL FIRE REGIMES AND THE CREATION OF CULTURAL LANDSCAPES

Gagadju, indigenous hunter gathers of Australia s Northern Territory, focus their subsistence activities on a coastal fringe penetrating no more than a few kilometers inland (Lewis, 1989; Nakashima, 1998). Two habitat types dominate this area of atlands: tall-open eucalyptus forest and eucalypt woodlands. Interspersed between these habitats are freshwater oodplains, paperbark swamps and rain forest stands. A steep sandstone escarpment dominated by Spinifex and other grasses as well as by shrubs, marks the inland boundary of the coastal atlands. This tropical savannah ecosystem has been and continues to be shaped by the Gagadju through the judicious application of re.

Burning practices are carefully orchestrated, paying close attention to season, habitat, wind direction, state of vegetative growth, moisture levels, previous burn locations and accumulation of debris. The Aboriginal calendar is divided into six seasons. Three of these constitute the wet period of the year: rst, a season of pre-monsoon storms; followed by the monsoon season; and nally the period of knock em down storms. The dry period follows, also divided into three seasons, beginning with a cool, humid season, then a cold weather season and nally a period of hot, dry weather. The Gagadju begin their annual cycle of burning towards the end of the wet period and conduct most burning activities during the ensuing cool and cold weather seasons of the dry period. During the hot, dry season when vegetation is extremely ammable and res are dif cult to control, burns are only conducted under very limited circumstances.

Burning Patterns on the Floodplains

With the end of the monsoon season, water levels on the oodplain begin to recede. Sedges and grasses, which spring up on the exposed ats, quickly mature and are dry before the coming of the knock em down storms. The Gagadju set their rst res in these dry grasses, knowing that the burn will die out along the edges of the rain forests and paperbark swamps (much too moist at this season to burn) and will continue outwards into the oodplains no more than some 2 10 m. These habitat types differ markedly in their sensitivity to re. When dry, the grasses of the oodplains, as those on the escarpment, burn easily and recover quickly. In contrast, the vegetation of rain forests and paperbark swamps is re-sensitive, recovering from a burn only with considerable dif culty. At intervals of a few weeks, the Gagadju ignite and burn successive strips of grasses as they mature and dry, proceeding in this fashion farther and farther out onto the oodplain. On each occasion, previous burn areas and fresh vegetative growths on moister soils serve to contain the re.

This burning of the oodplains serves several purposes. First, the early res around the perimeters of rain forests and paperbark swamps create re barriers that shelter these fragile habitats from res occurring later in the season. Second, the razing of mature, dry stands of grasses triggers a regrowth, whose tender leaves lure kangaroos and wallabies out from adjacent rain forest stands in the early morning and late evening, thus offering the Gagadju hunting opportunities. Finally, the Gagadju note that res also favorably alter the oodplain habitat for the nesting of waterfowl, particularly magpie geese.

Creating Fire Mosaics

Beginning during the cool season and at the start of the cold season, the Gagadju set res in the tall-open forest and eucalypt woodland habitats that dominate the coastal atlands. These habitats are highly susceptible to burning and at the same time, well adapted to re. In the understory, leaf litter accumulates quickly and has high oil content, while sorghum grasses provide a dense cover. While these burn easily when dry, the vegetation is nevertheless quick to recover. Thick bark shelters eucalyptus trees from understory res, and high canopies reduce the likelihood of res spreading into the forest crown. Wind intensity and direction are important allies. The Gagadju use strong midday winds to aim the re towards areas of moister vegetation or previous burn sites to limit the extent of the burn. Furthermore, strong winds prevent heat and ames from licking up into the forest canopy, thus protecting trees in ower that will subsequently provide humans and animals with edible fruit. Early in the cold season the res go out after a few hours and burn relatively small areas. As the season progresses, the vegetation becomes successively drier, and res burn longer and cover larger areas.

Fires in these wooded habitats serve a number of functions. Circles of re are used as a hunting technique, driving animal prey to waiting hunters. By removing surface vegetation and debris, burning facilitates the gathering of yams and roots and the hunting of goannas (Figure 2). Burn sites attract kangaroos and wallabies that come to graze the fresh re-growth of grasses. Furthermore, these serial burnings create an ecological mosaic composed of sites at different stages of recovery from burning. This heightens biological diversity and provides the Gagadju with a choice of subsistence opportunities. Finally, regular bouts of controlled burning impede the growth of thick tangles of underbrush and prevent the dangerous build-up of leaf litter and debris that can result in uncontrollable wild res.

The central role of traditional Aboriginal burning practices in maintaining biological diversity, and in creating

Figure 2 Shaping landscapes with fire: Aboriginal peoples use controlled burning to maintain a habitat mosaic that offers a variety of foraging opportunities. Here a woman sets off to hunt goannas on a newly burned site (Northern Territory, Australia). (Photo by B Glowczewski)

and maintaining the cultural landscapes of Australia, has gained official recognition by National Park authorities in certain parts of the country. In Kakadu and Uluru National Parks the re-establishment of traditional Aboriginal burning regimes has become an explicit Park management goal.

CASE STUDY 2: SWIDDEN CULTIVATION AS SUSTAINABLE PRACTICE – THE KAREN OF NORTHERN THAILAND

Slash-and-burn (*swidden*) agriculture continues to be an important mode of agricultural production in many parts of Africa, Asia, South and Central America and the Pacific (*see* **Shifting Cultivation and Land Degradation**, Volume 3; **Swidden**, Volume 3). It has also been at the heart of one of the most prolonged and vociferous debates over the sustainability of this traditional practice. While the debate is far from closed, there is growing awareness today that swidden agriculture as practiced by many indigenous peoples is not only sustainable, but also contributes to other pressing global concerns including conservation of domestic and wild biodiversity, as well as carbon storage.

Land Use Strategies of the Karen

The Karen land use strategy is based upon the maintenance of several major categories of land that can be distinguished by their use, location and the pattern of ownership: rice paddy fields, areas of swidden cultivation, community forest and watershed forest (Figure 3) (Rerkasem and Rerkasem, 1994; Nakashima, 1998). Rice paddies are owned by individual families and tend to be established close to the village, often at the base of slopes where sediment fans have been created by the erosion of soils from swidden fields above. Lands used for rotational swidden agriculture are much more extensive, lying in a broad band surrounding the village. Families divide their holdings into plots among which cultivation is rotated on a 7–10 year basis. Fields are cultivated for only one or two seasons before being returned to fallow. The different types of forested areas, unlike rice paddies and swidden fields, are held as common property. The extensive community forests provide the Karen with wood and other forest products, as well as serving to graze livestock. Watershed forests harbor the headwaters of major water sources and are denoted as sacred.

Creating and Maintaining a Biologically Diverse Landscape
